Subdivided into GENERAL (including AUTHORS.) ENGINEERING LITERATURE and CONTRACT PRICES

INDEX

EXPLANATORY NOTE

This index follows, for the most part, the methods adopted, and more fully explained, with the index for Volume 71. An asterisk (*) indicates an illustrated article and (n), (ns) note, notes. Letters are not specified as such, nor are editorials usually. An editorial referring to an article may be indexed by appending the page number.

Following is a list of the pages included in the several numbers of this volume, by date;

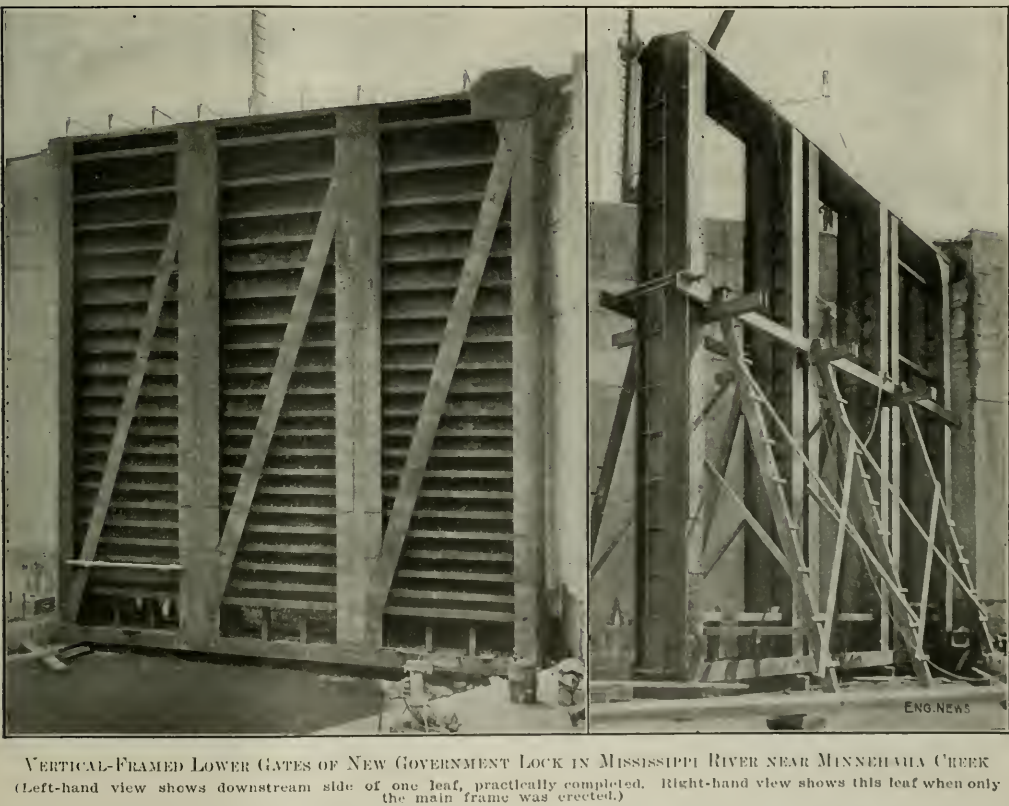
VOLUME 72 JULY 2, 1914 NUMBER 1

Vertical-Framed Lock-Gates, St. Paul-Minneapolis Dam

A rarely used form of lock-gate has been adopted for the 31-ft.-lift lock of the new government dam across the Mississippi River at Minnehaha Park, between St. Paul and Minneapolis. The gates do not miter except at the extreme top, where thrust blocks are fitted to the meeting ends of the gates and to the hinge joints; the rest of the gate pressure, or two-thirds of the total, is carried lower gate-recess to lift wall near upper gate. Each leaf is 47 ft. 3 in. long by 49 ft. 3 in. high over all, which brings its top about 39 ft. above the probable low-water level in the lower reach, and about 2 ft. below the estimated extreme flood level of the pool above (when a 10-ft. depth of water flows over the dam). The two gates, designed for maximum stresses of 12,000 lb. per sq.in., weigh about 300 tons. They were built by the Independent Bridge Co., of Pittsburgh, Penn., and erected by the U. S. Engineer Office, St. Paul, which is constructing the



Vertical-Framed Lower Gates of New Government Lock in Mississippi River near Minnehaha Creek
(Left-hand view shows downstream side of one leaf, practically completed. Right-hand view shows this leaf when only the main frame was erected.)

by direct bearing of the gate leaves against the sill. Thus the body of the gate leaf must transfer the water pressure vertically to the sill girder at the bottom and the miter or arch girder at the top, instead of horizontally to hinge joint and miter joint. This gives the type its name—vertical-framed gate.

The lock is 80 ft. wide by 350 ft. long between gate quoins, or about 365 ft. long from the upper edge of dam and lock on force-account. The cost of material and erection of the gates was unusually low, on account of the simplicity of design and the low stresses resulting from the type of framing.

In this type of gate, only one-third the arch-thrust of the mitering type of gate has to be carried, since two-thirds the water pressure goes direct to the sill. As height and width of the gate are practically equal, the lengths of

main beams would be about the same whether vertical or horizontal. However, the arrangement of the beams is somewhat more economical in the vertical-framed type, as it is possible to use vertical main beams and horizontal secondary beams, arranged with sole regard to economy of metal. Further, the thrust being reduced by two-thirds, the abutment or quoin castings are reduced correspondingly, in weight and cost.

Two views herewith show the gates during erection. They are now completed except for the water-stop members at hinge and miter joints, and the operating mechanism. The plating of the gates is at mid-depth of the girders, the secondary framing beams being shallow enough to permit this. This arrangement was utilized to reduce the uplift when the lock is full, to an amount corresponding to half the ground-plan area of the gate, which is enough to nearly balance the weight of the steel.

Lieut.-Col. Charles L. Potter is in charge of the construction of the lock and dam. Geo. W. Freeman, Assistant Engineer, designed the structures and is carrying out the construction work as superintendent.

A Private River-Straightening Enterprise at Cleveland

One of the many windings of the Cuyahoga River at Cleveland, Ohio, is being straightened by a cutoff, but private enterprise is doing the work for its own interests, on the basis of plans worked out and approved by public authorities. Work was begun last season, and by the end of 1914 it is expected to be so far along that water will flow in the cutoff channel. Filling the old channel will probably require the 1915 season.

The sketch map, Fig. 1, shows the location of the work now in hand (hatched portion near southerly end), and several projects proposed (more or less definitely) for acquisition of the entire width of the bottoms by Cleveland capitalists forming the Cuyahoga Valley Realty Co., and the sale by them of the westerly half to the Otis Steel Co. The project for the cutoff was worked out by the City of Cleveland, however, through its River and Harbor Commission and the City Engineer's office (Robert Hoffmann, City Engineer; E. B. Thomas, Assistant Engineer in charge of river and harbor). The U. S. War Department gave its approval to the proposed work in January, 1913. The central part of the work is being

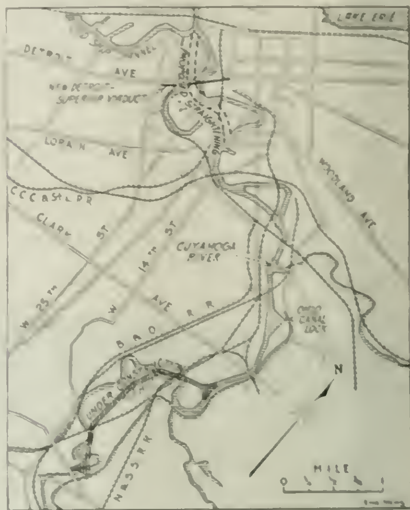


Fig. 1. Cuyahoga River, Cleveland, O., Showing Straightening Proposed and in Progress

Figs. 2-4. River-Straightening Work in Progress

(Fig. 2. Looking toward hill to be removed on line of new channel. Fig. 3. Steam shovel at work. Fig. 4. Fill made from steam-shovel excavation.)

the near future. A cutoff passing under the easterly part of the new Detroit-Superior viaduct was projected but has been abandoned; instead there may be cutoffs both upstream and downstream of the viaduct, leaving the present channel at the viaduct.

The valley of the Cuyahoga for three miles below the [illegible] viaduct forms a broad bottom over a mile wide. To the upper half of this stretch the present straightening enterprise is limited. It will divide the width of the valley into almost equal strips, and will give to the new plant of the Otis Steel Co., east of the new channel, an unbroken width of ground [illegible] fronting the full length along the new channel.

The construction of the cutoff came about through the done under direction of the Otis Steel Co., and is paid for by this company and the realty company. About one-third of the total length of the new channel, the upstream and downstream ends, will have to be constructed by the city (alone or in coöperation with private interests) on account of land-ownership difficulties and other reasons.

The location of the new channel cuts right across a hill rising some 100 ft. out of the bottom land. The first construction work was making the cut through this hill. This was steam-shovel work, the spoil, moved by cars, being used to fill low-lying ground nearby. The views, Figs. 2 to 4, show the shovel work in progress, and indicate the character of the valley generally.

Dredging was begun in a small way last season, but

primarily as regular work on the cutoff but for the purpose of obtaining sand, outside parties doing the dredging at their own cost. This was not carried very far, however, because of too much clay in the soil

Dredging by the contractor for the cutoff is to begin shortly, with equipment specially built for the job. Expectations are that it will progress fast enough to open the channel through the hill before 1915. The dredge is a suction dredge with electric-driven pumps, set in a light-draft hull, and supplied with power by pole-line. The American Shipbuilding Works, Cleveland, built the hull, and the Marion Steam Shovel Co. furnished and placed the machinery.

P. T. McCourt is contractor for the cutoff. The total cost of the work will be about $1,000,000.

A Safety Fire Escape*

The fire escape shown in the accompanying sketches has been installed in the printery of the Travelers' Insurance Co., at Hartford, Conn. Its distinguishing feature is a design whereby the lower flight is normally in a horizontal position well up from the ground, but is automatically swung to the ground by a person coming down the flight next above. The general outline is given in Fig. 1 and the details of the releasing mechanism in Fig. 2.

The projection at the free end of the stairway (Figs. 1-2) rests upon a lever, when the stairway is in the horizontal position (as shown by the dotted lines in Fig. 1), which lever is itself supported by a bracket and by bolts

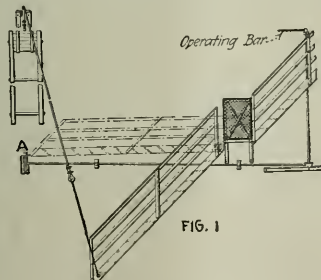

FIG. 1

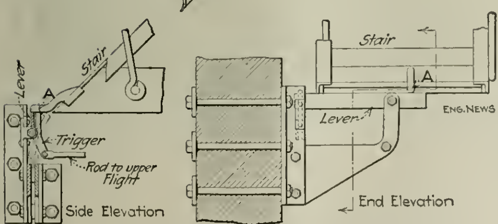

FIG. 2

FIG. 1. OPERATION OF THE SWINGING STAIRWAY
FIG. 2. DETAILS OF RELEASING MECHANISM

passing through the wall. Heavy plates are used between the nuts and the inside of the wall. A trigger fulcrumed to the bracket engages the lever and thus supports the stairway in the horizontal position. The lower end of the trigger is pivoted to a horizontal rod, which passes along the side of the wall through supports to a box, to which a vertical rod is connected, through a cam within the box. This vertical rod passes between the wall and the stairway to a point about half-way up the upper flight; the brackets are bolted to the wall to support this rod. The upper end of the rod is connected to the operating bar, which normally extends across the stairway.

In case of fire, a person coming down the stairway pushes against the operating bar and swings it against the wall. This causes the vertical rod to turn the cam in the box so that it pushes the horizontal rod and releases the lever by operating the trigger. The hinged stairway now being unsupported, tilts the lever and swings to the ground; the counterweight is purposely made too light to support the entire weight of the stairway. These operations take place before the person who moves these levers has reached the lower balcony; and upon reaching this balcony, therefore, he has a continuous solid stairway before him.

In moving from the horizontal to the inclined position, the stairway has a shearing action. The wire-mesh guard, shown in the upper diagram, is therefore provided to prevent accidents.

*Abstracted from the "Travelers Standard" for May.

An Engineering Competition for Students

A competition in the solution of engineering problems, open to students in technical colleges, has been recently completed by the Engineers Society of Western Pennsylvania, under the direction of its committee on Engineering Education. The results have been so satisfactory that a second competition will be arranged for 1914-15.

One problem was offered in each of the fields of civil, mechanical and electrical engineering. Copies were sent Oct. 15, to deans of engineering schools in which students wished to compete, four months actual work being allowed and a copy given to each competing student. An explicit statement of sources of information and procedure accompanied each. Contestants were third- or fourth-year men working alone or in pairs; solutions represented no assistance beyond the printed data and "such general discussion as was consistent with honorable competition." The prizes were a first, second and third "certificate of award" and "honorable mention," in each class. The judges were (I) Civil Engineering: Paul L. Wolfel, Chief Engineer, McClintic-Marshall Construction Co.; Richard Khuen, Jr., General Manager of Erection, American Bridge Co.; (II) Mechanical Engineering: O. P. Hood, Chief Mechanical Engineer, U. S. Bureau of Mines; F. C. Biggert, Jr., Chief Engineer, United Engineering & Foundry Co.; (III) Electrical Engineering: William Hoopes, Electrical Engineer, Aluminum Co., of America; W. Edgar Reed, Consulting Engineer.

The civil-engineering problem was the design of a country highway bridge—given survey notes, unit prices, etc. The mechanical-engineering task was the design of a grinding machine taking castings up to 12 in. wide. The problem in electrical engineering was to design a system by which 30,000-volt alternating current was transported and converted to 550-volt direct current.

Those receiving the first awards were: In civil engineering H. W. Terhune and R. W. Hill, Tufts College, Boston; in mechanical engineering, F. C. Eastman and A. D. Stewart; in electrical engineering J. R. Lambach, Georgian School of Technology.

Two Recent Water-Power Plant Accidents

Two accidents of rather unusual character have recently occurred at water-power plants located in the State of New York. In one the ashlar face of a 14-year old masonry dam slid off for the whole length of the dam under conditions not obviously abnormal; in the other a moderate flood was diverted, mainly by an incompleted culvert, in an undesigned direction with the result that about 700 ft. of new macadam roadway was destroyed by a serious washout that also undermined the foundations of 150 ft. of 7-ft. steel penstock.

Dam Face Failure

The dam affected is located at Hannawa Falls, St. Lawrence County, New York, and forms the storage reservoir for the Hannawa Falls Water Power Co. On the morning of Mar. 1, the Potsdam sandstone ashlar facing

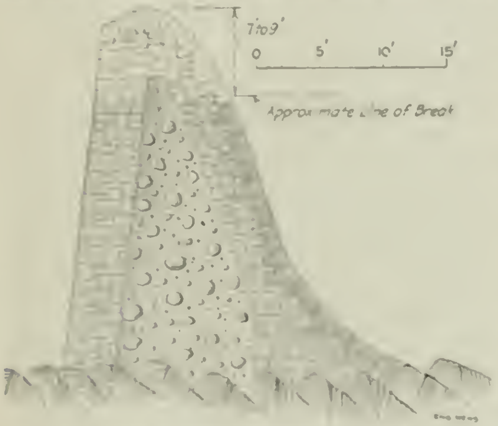

FIG. 1. CROSS-SECTION THROUGH HANNAWA FALLS DAM, SHOWING BREAK IN ASHLAR FACING

of the downstream side of the crest of the dam slid and broke off for a distance of about 7 to 9 ft. below the crest and throughout practically the entire length of the crest of the dam. This dam was constructed in 1900, having a cross-section as shown in Fig. 1,* the central core being concrete. The upstream rubble facing was injured to some extent but not to as great a depth as on the downstream side. The line of fracture occurred at the plane of contact between the cyclopean concrete core and the masonry facing. The concrete core remained intact.

The flow of the stream was relatively small at the time, being reported as follows at the nearest gaging station at Parishville: Feb. 27, 445 cu.ft. per sec.; Feb. 28, 417 cu.ft. per sec.; Mar. 1, 395 cu.ft. per sec.; Mar. 2, 373 cu.ft. per sec.

The drainage area at Parishville is 789 sq.mi. and that of Hannawa Falls about 1100 sq.mi. The dam formed a pond of about 200 acres area, which was covered with thick ice at the time of the accident, by the dam. Owing to the low stage of the stream, the water was quickly drawn down below the level of the injured portion of the dam.

Various theories have been offered to explain the injury to this dam; including, first, direct ice pressure against the ashlar coping above the level of the concrete; second, injury to or disintegration of the ashlar masonry by moisture and frost. Potsdam sandstone is a comparatively soft porous material. In view of the fluctuation in water-level in the pond and the manner of the dam failing without injury to the concrete core or upstream face comparable to the injury of the downstream face, it appears that no theory yet advanced is satisfactory.

Road and Penstock Washout

The washout described below occurred during the last part of April near another water-power plant in the northern part of the state. The plant in question has a solid masonry dam forming a pond which is crossed by a highway about 50 ft. above the dam. The highway, after crossing this bridge, turns away from the downstream face of the dam and runs along a sidehill, at the bottom of which is the gorge of the dammed stream. Between this gorge and the highway there was a 7-ft. steel penstock, built in a trench excavated in the loose sand and gravel which overlies the rock.

The results of the washout are shown in the view in Fig. 2, which is from a photograph taken looking along the sidehill toward the dam in the right background. The washout, alongside of the road and directly under the destroyed penstock, is in the center of the view and the highway is shown at the extreme upper left.

The flood was a sudden one, arising from the melting of the snow in the woods after a rapid rise in temperature. Although the flood was of unusual volume, the discharge over the dam did not reach the spillway capacity. The immediate cause of the washout was water following down the penstock trench to a gulley, where it accumulated and broke through the bank into the gorge below. The loose soft material—sand, gravel, and sawmill waste—was easily eroded, undermining the highway for about 700 ft. and the penstock for about 150 ft. The water which did the damage apparently came from two sources, partly from the pond above the dam and partly from hillside drainage from the slopes to the left of the dam looking upstream. This drainage came down the highway to a point where the macadam road turned to cross the bridge above the dam. Near this turn in the macadam road was a culvert intended to carry this hillside drainage into the river. Owing to the lateness of the season when the work was finished, no channel had been provided to take the discharge of this culvert after it crossed the highway, and the flow through the culvert entered directly into the penstock channel.

At the time the water in the pond reached a sufficiently high stage to flow over the highway, the water in the pond was rising very slowly and in fact did not rise to any appreciable height after the washout started. Damage from this source could apparently have been avoided by the simple expedient of throwing up a loose sand embankment 40 or 50 ft. long and not more than one foot high along the highway. However, the only persons present were the operatives of the power plant who, seeing the danger, devoted their entire attention to clearing the headgates. As a result, the water was diverted on

*Taken from a paper, "Water Power Development at Hannawa Falls," by W. G. Atwood, Trans. Am. Soc. C. E., Vol. 49, 1902.

of the penstock before any portion of the penstock was undermined.

The injured penstock was taken apart in sections; sent to the nearest boiler works, rolled into shape and is at this time being put back into position.

The drainage area above the dam is 110 sq.mi. There are numerous lakes and a broad flat valley with deep sand deposits which acts as a very extensive natural regulator, so that in spite of the precipitous rock slopes surrounding the basin, the runoff is very regular. The maximum discharge of the stream at the time of the accident is estimated to have been in the neighborhood of 1500 cu.ft. per sec. Judging by the reported conditions and from the cross-section of the channel where the water flowed over the highway, the quantity of water passing around the end of the dam apparently could not at any time have exceeded 100 cu.ft. per sec. Inasmuch as this channel was greatly increased in area by the washing out of a section of the highway, it appears probable that the quantity of water which flowed around the end of the dam did not at any time exceed 40 to 60 cu.ft. per sec. The fact that many thousand yards of earth were removed during the period of a few hours by this small quantity of water is due to the extremely loose character of the material excavated. The penstock was constructed in a trench excavated in the loose sand and gravel which overlies the rock. The work was completed late last fall and as excavated material had frozen the trench was not refilled.

Fig. 2. Washout of Highway and 7-Ft. Steel Penstock Due to Bypassed Overflow from a Dam and to Side-Hill Runoff

Cleaning and Repairing the Sudbury Masonry Aqueduct of the Metropolitan Water Works, Boston, Mass., is described in the recently issued annual report of the Metropolitan Water and Sewerage Board as follows:

Two gangs of men were employed one beginning at each end of the section to be cleaned and working toward each other. One gang used water and hand brooms in cleaning the sides and top of the aqueduct, a wagon with a tank body being used when cleaning the top. The second gang made use of a gasoline power sprayer, by which water under 200 lb. pressure was discharged against the interior surface of the aqueduct. This method proved more efficient, more economical and quicker than the hand method. The cleaning of the bottom was done with push brooms operated by hand. The ironwork of the gates and stop-plank grooves in the screen and terminal chambers was thoroughly scraped, dried by the use of torches, and painted with two coats of red lead and oil. When the aqueduct was first emptied it was found that water was flowing in through small crevices in the brick and concrete, the greater number of which were where the aqueduct is generally in tunnel. In this section 1400 leaks in the tunnel lining were repaired by driving the calking wedge lead, tea lead or lead wool into the joints. The cost of cleaning and repairing this section of the aqueduct was as follows:

	Labor	Materials	Total
Cleaning aqueduct	$270.05	$1.58	$274.63
Cleaning and painting ironwork	121.00	21.27	142.27
Repairing leaks in masonry. . . .	96.75	37.10	133.85
	$487.80	$62.96	$550.75

General Observations on Street Pavements of European Cities*

By Henry Welles Durham†

SYNOPSIS—In the summer of 1913 Mr. Durham was commissioned by the Mayor of New York City to attend the Third International Road Congress at London and to take several months to study European pavements, which from time to time had been compared with New York City pavements, to the disadvantage of the latter, by the popular press. In this article Mr. Durham summarizes European paving practice in such a way that municipal engineers may know just what foreign practice is and just what results have been attained.

Foundation

Up to the middle of the last century, the pavement consisting of stone blocks laid directly on the ground surface of the street was considered satisfactory in all European cities. At the present time, such a surface is used on a great part of the streets in every European city.

It was not until the year 1890, when was first commenced the placing of electric wires in underground conduits instead of on overhead poles, followed within a few years by the introduction of motor-driven vehicles in large numbers, that the necessity for a rigid foundation under a separate wearing surface for city streets assumed great importance.

At the present time, due to the great increase in weight of traffic on the streets of cities of the first class, and to the frequent necessity for opening them for the laying of various substructures required by conditions which have arisen within the past 25 years, there is universal agreement among those in control of city highways that concrete foundations are indispensable when constructing new pavements in important thoroughfares.

Such foundations are essential in almost all streets of American cities, which, in addition to having been disturbed for subsurface construction, are very largely on regraded ground; whereas many of the older cities of Europe have streets which have occupied their present position for hundreds of years; and where, as can be seen in Hamburg in the case of a street not subject to frequent opening, the stone block surface can be satisfactorily maintained on the original hard soil underlying it.

Fig. 1. Method of Construction, a 12-In. Concrete Foundation for Soft Wood Block; All Hand Mixing; Gracechurch St., London

Fig. 2. Finishing a Concrete Surface for Hard-Wood Blocks; Rotterdam

Subsurface conditions in London, on the other hand, due to the nature of the underlying material, are such as to justify the authorities there in demanding the heaviest foundations to be found anywhere, 12 in. being used in the central part of the city. But even in London there were found in the outlying residence districts a large proportion of satisfactorily surfaced streets without an artificial foundation.

Great differences exist as to the thickness of concrete foundation where used, and the proportioning of materials composing it. Concrete 4 in. thick is regarded as satisfactory in many places, even in such an important city as Brussels. Probably the standard thickness at the present time is from 6 to 8 in. The proportions in which foundation concrete is mixed vary greatly. For purposes of comparison, Table I shows some of the various proportions used abroad.

*Abstract of Chapter XII of the forthcoming report on "Street Paving and Maintenance in European Cities" to the Mayor of the City of New York.

†Chief Engineer, Bureau of Highways, Borough of Manhattan, New York City.

TABLE I

	Cement	Fine Aggregate	Coarse Aggregate	
London:				
City and Westminster	1	..	6	Thames ballast—unscreened river gravel
Lewisham	1	..	7	Thames ballast—unscreened river gravel
Battersea	1	3 sand	5	clean gravel
Liverpool	1	6 crushed slag	3	broken stone, 3-in. gage
Paris	1	3¾ sand	7½	stone or gravel
Berlin and Charlottenburg	1	..	8	fine gravel and sand
Hamburg	1	..	7	unscreened river gravel
Vienna	1	3 sand	5	gravel

The concrete is commonly laid between forms set transversely to the axis of the street at intervals of about 15 ft., materials being turned over on a mixing board between these forms directly into place. Final finish to the surface is then obtained by drawing a straight-edge across the width of the street, the concrete being mixed wet enough so that finer material flushes to the surface and produces a fairly smooth finish under the straight-edge.

Where this method is not followed, the forms are placed longitudinally and the finished surface obtained by drawing along on them a template formed to the proper transverse section.

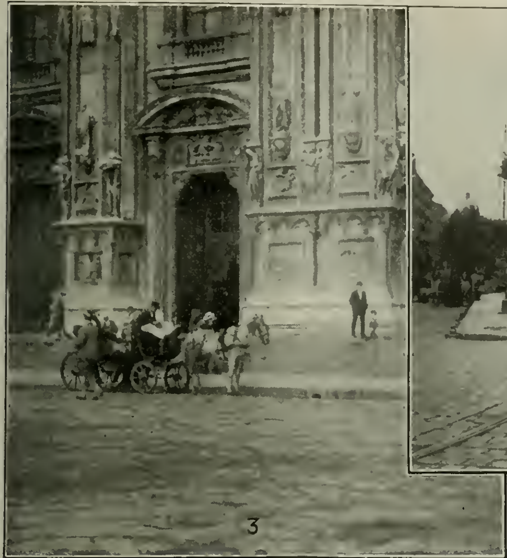

Fig. 3. Large 18x24-In. Stone Blocks in Front of Cathedral at Milan

Fig. 4. Large Stone Blocks, 8x10 In., Laid on Sand Foundation, Vienna

Fig. 5. Granite-Block Pavement, Liverpool

Typical Stone-Block Pavements in European Cities

The work of concrete mixing is done almost entirely by hand, although concrete-mixing machinery has been introduced in Germany to a small extent. The subfoundation is generally rough graded, with about the same accuracy prevalent in New York City, but it is more usual to finish the concrete surface smooth.

Where wood pavement is to be laid, particular attention is given to obtaining an accurate, smooth surface, and a certain amount of hand-smoothing is sometimes employed. It was noted in London and in other cities,

however, that by employing the method of accurately setting transverse strips to the surface grade on narrow widths of concrete, and then drawing a straight-edge or a screed along on these adjacent strips (between which the work of mixing and placing was carried on), that a sufficiently smooth finish was obtained with very little surfacing. For asphalt and granite pavement, it is not attempted to obtain such smooth results on the foundation surface; but usually a more accurate surface is obtained on all classes of work than in this country, though it is at the sacrifice of speed. The quality of the concrete is in no case inferior to that being produced at the present time in New York City; and frequently it is inferior.

Fig. 6. Liverpool Pavement of 4-In. Cubes

Fig. 7. Birmingham Alley Paved with Small Cubical Blocks on a 7-In. Slag-Cement Foundation; Pavement Less Than 2 Years Old

Fig. 8. Hamburg Pavement of Large Stone Blocks, of Remarkably Uniform Surface; Fairly Heavy Traffic

Typical Granite-Block Pavements in Europe

Stone Pavements

Perhaps the most frequently used block in Europe is the squared block having generally cubical dimensions, of the type known in this country as "Belgian" block. These blocks are usually laid without foundation, but their irregular shape permits of joints not exceeding 1 in. in width and a surface much smoother under wheel traffic than that of the old-style cobble.

Another variation, but of the same class, is the type of large slab block pavements employed in Italy and other of the more southern countries, composed of stones measuring from 18 to 24 in. on top, and having a 6-in. depth, laid with comparatively close-fitting joints. On a level street these pavements furnish fairly good foothold for horses, and still have a smooth surface under wheel traffic.

Variations from the cubical shape of the "Belgian" block were introduced in German and English cities approximating more nearly to the dimensions of our granite paving block of today, but having the same general quality and wide joints as the old "Belgian" block.

A great part of the stone-paved streets in the continental cities (constituting generally a majority of the total area of carriageways) is paved with one or another of the above types of block, either a granite or a material like trap, the latter called whin stone in Great Britain and porphyry in France and Germany. The granite, being a softer material and subject to more rapid wear, has not been so largely employed in the past, except on grades where its lack of extreme hardness makes it less slippery for horses' feet.

With the introduction of concrete foundations under stone pavements, came a reduction in the depth of blocks, and today where this foundation is used in France and Germany, the blocks have a depth of from 5 to 6 in., instead of 8 in. or more, as when laid without foundation.

In the German cities, two standard types of specifications are recognized for these two classes of pavement, and where concrete foundation is employed stones of smaller surface area and more closely dressed are used.

As characteristic of the extent to which concrete foundation is employed under stone pavements on the continent, however, reference may be made to the city of Paris, where only one-eleventh of the entire area of stone-block streets is so constructed. Liverpool has tried a great number of different types of block, both with and without concrete foundation, although for the past 25 years concrete foundations have been almost always used.

The fact that certain peculiarly shaped blocks are giving satisfaction in the streets of Liverpool does not indicate that this type of block is a standard nor one to be recommended for employment at the present time, because much difficulty is now experienced in obtaining any but the standard set from the Welsh and Scotch quarries which supply the English cities.

The best foreign practice is to lay stone pavement on a concrete foundation, as in this country, employing a cushion of sand or fine stone screening of 1 in. to 2 in. thickness, sometimes mixing in a small proportion of cement, in order to have subsequent rigidity in the cushion.

Joints are sometimes filled with gravel or fine crushed stone and then poured with tar or with a mixture of tar and sand; or, as is the practice in some cities, with a liquid cement grout. A combination of the two methods, using a mortar filled joint for half the depth with tar at the top, is sometimes used. For the large areas of stone pavements with no foundation, a great proportion has no filler in the joints other than fine gravel or sand.

On account of the lower rate of wages paid in Europe, it is possible to produce blocks more accurately dressed for the same amount of money than can be done in this country. Usually, a small amount of tool work can be done on the sides in order to permit the block to be laid with closer joints, but only in isolated instances where specially dressed blocks are employed are the joints less than ½ in. in width.

Fig. 9. Laying Replaned Old Hard-Wood Blocks on New Concrete Foundation, Birmingham

Fig. 10. Laying Rock Asphalt Pavement; Spreading Hot Asphalt Powder; Hand Ramming; Berlin

Fig. 11. Victoria Embankment, London; American Asphalt on Macadam Foundation; Granite Blocks on Tramway

There were nowhere found any road authorities who recommended small cube-block pavement (that is, blocks 2 in., 3 in., and 4 in. on the side) as a competitor or sub-

stitute for the large granite-block type of pavement on a concrete foundation. Where laid in England, the small cubes are used as an alternative to some type of bituminous concrete.

The small-cube pavement streets and roads in Germany are almost always a means of substituting a harder surface for ordinary water-bound macadam. The blocks are frequently laid with sanded joints as a carpet coat on the old macadam, and when laid on a concrete foundation with tar-filled joints, they are still employed only on streets of light traffic where bituminous concrete or a sheet-asphalt surface would otherwise be used.

The engineers in Birmingham and the Borough of Chelsea have found the small-cube pavement satisfactory; the engineer of Battersea does not think it adaptable for employment on a city street. The experimental lengths laid on the Sidcup Road running out of London, where the small cubes have been used in competition with various other types, are too new to allow the drawing of definite conclusions, but appear to have been satisfactory up to the present time. The Liverpool engineers do not consider the small-cube pavement suitable on any class of city street, and they regard the rectangular granite block as best for heavy traffic and the bituminous macadam the best for the light traffic residence streets.

FIG. 12. BRICK PAVEMENT NEAR DOCKS, AMSTERDAM

The advantages of the small-cube pavement for suburban roads are: Low cost of maintenance and absence from dust when constructed with tar-filled joints. The disadvantages appear to lie in its noisiness, the tendency of the blocks to wear round due to wide joints, and their liability to become displaced and cracked on account of their small size. Cases were observed where this type of road surface showed material wear both under high-speed pleasure automobile traffic and slow-moving steel-tired motor and horse-drawn heavy traffic.

There are a few instances abroad of small areas laid with specially dressed granite block at a cost much in excess of anything we have, and presenting a surface almost as smooth as asphalt. But even could such a pavement be laid economically in this country, it is doubtful whether it would be advisable, on account of its having a surface too smooth and slippery.

WOOD PAVEMENTS

There are two classes, soft pine and hardwood. The blocks have dimensions approximating those used in this country—a depth of from 3 to 5 in., a width of 3 to 4 in., and a length averaging between 6 and 10 in.

Australian hardwood has been very extensively laid, both in England and on the Continent. Wherever it has to carry heavy traffic it has proved unsatisfactory. The blocks have a tendency to wear round and become rough and uneven. Some attempts have been made to take up the blocks from streets where this has occurred, plane off about ½ in. from the heads and relay them. This has been done with some success in various cities, but it is at best a temporary expedient, and in no city of first importance is it regarded as desirable to lay hardwood blocks at the present time. The blocks are always laid directly on a smooth concrete surface, being previously hand-dipped in tar and the surface poured with the same material. Soft wood blocks, made of Norwegian, Swedish and French pine and similar material, somewhat softer than our long-leaf yellow pine but very much resembling it in appearance, are being used with great success at the present time.

In the construction of soft wood-block pavement, the concrete foundation is finished with a perfectly smooth surface to the proper crown of the street and the blocks, previously treated with from 4 to 12 lb. of creosote oil per cu.ft., are laid directly on this surface.

After the blocks are laid in place, and this is usually done with the joints a trifle less close than in the American practice, the surface is swept with tar, which has been hand poured, as a joint filler. When this has sufficiently hardened, the entire surface is gone over with a thin coating of liquid cement grout, presumably to reduce the amount of stickiness from the tar, and the street is finally spread with a layer of granite screenings or crushed gravel, which traffic soon rolls into the soft surface of the wood. This produces a gritty nonslippery surface, which permits this type of material to be laid on grades up to 5% with entire success, under horse-drawn traffic. When well done, a wood pavement presents undoubtedly the finest street surface in existence; when the contrary is the case, they are about as poor as any to be found.

ASPHALT

The asphalt pavements of European cities are largely constructed from the natural asphalt rock found in various parts of Italy and southern France. It consists of a limestone impregnated with bitumen, which is mined in rough fragments, and run through a crusher and mill, and after being reduced to a fine powder, is heated to a high temperature, producing a material similar in consistency to the artificial asphalt topping used in this country, but it is of a brown color. The heated material is taken to the streets in wagons, spread to a depth sufficient to give a final thickness of from 1½ to 2 in. on the concrete foundation, and, after a preliminary rolling with a hand roller, is given its final compression by hand-ramming. Where the rock contains a deficiency in the amount of bitumen necessary, the required addition is made.

The City of Paris prohibits the reuse of any of the old wearing surface removed from the street, but on new pavements in Berlin and Charlottenburg the contractor is permitted to employ this old material in the proportion of about one-third of the total quantity. The practice is to take the old wearing surface as it is brought in carts

to the plants, mixing it in alternate layers with the broken rock from the mines, the mixture then being run through the crusher.

Rock-asphalt pavement has been employed for a long time in the principal European cities, producing a surface very similar to asphalt pavements of American cities, but somewhat harder and possibly a trifle more slippery under cold-weather conditions. In extreme warm weather it is liable to the same tendency encountered in this country to soften and roll. It is successfully employed in London, Paris, and Berlin, on streets that would not be regarded as suitable for our type of asphalt. It is nowhere regarded as satisfactory on any grade.

Abroad, asphalt pavement is usually thought to be too high priced to employ in quiet light-traffic residence streets to the extent followed in New York City. All new districts in Berlin, however, are being developed by asphalt roadways, and Paris has made contracts for the repaving with asphalt of a large extent of the existing wood, stone block and macadam. Vienna is now undertaking an extensive repaving of its old stone-block streets mainly with asphalt.

There have been some attempts to introduce American asphalts in competition with the European. The Thames Embankment has a Trinidad asphalt surface on the old macadam foundation, which has given satisfaction. A few experimental lengths of American asphalt have been laid in Berlin, and a company now operating there is preparing to make contracts for the use of some of the asphalts from this country. In general, however, the foreign engineers are satisfied with their own type of material and are somewhat averse to trying experiments with another.

The point must be emphasized that many of the superior features in regard to foreign asphalt streets, as they strike the observer's eye, are directly attributable to the much better and more thorough street-cleaning system in operation; while the points of criticism based on the condition of certain American asphalt streets can also be attributed in many cases to the faulty foundation conditions, which have not prevailed abroad.

Summary

These three types of surface—rectangular stone block, wood block, and compressed rock asphalt—are the prevalent surfaces for modern city street construction in the great cities of Europe. A great variety of other types can be found in small amounts and generally used where traffic is light. These include various kinds of compressed asphalt block, usually a thin slab or plate laid on concrete foundation; concrete blocks cast in forms under pressure, usually large slabs and laid more often for sidewalks than for other purposes; slag blocks, which present a smooth surface when new but rapidly deteriorate even under light traffic conditions; and brick, both ordinary hard burned and vitrified. Hard-burned bricks dipped in tar have been used in Brussels on some of the parkways, and there are many miles of brick roads in Holland.

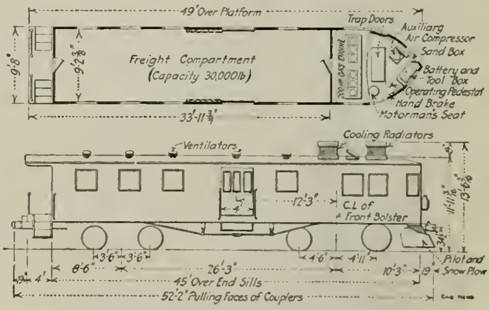
All classes of tar and bituminous macadam made under many processes, some of them patented and with various names, are being tried out and extensively used for suburban and country-road traffic, as in the United States. Tar macadam particularly is being largely introduced in the residence districts of European cities, under conditions similar to those where sheet asphalt on concrete is so often employed in the Borough of Manhattan, New York City.

After classifying all improved and modern pavements, it is found they are much in the minority as compared with those which may be termed ordinary or usual—large stone blocks on sand, or water-bound macadam.

A Self-Propelled Convertible Freight Car*

The Minneapolis & Northern Gasoline Motor Ry. has recently purchased a motor freight car to be used for freight and express service between Minneapolis and Anoka. It is a semiconvertible car which, during periods of heavy passenger traffic, can be used for transportation of passengers—removable seats and chairs being installed for that purpose.

The accompanying floor diagram and side elevation illustrate the general design of the car, from which it will be noted that the front end is wedge shaped and the rear end has a platform for passengers' ingress and egress. The now familiar depressed side-center entrance has not been used. The car structure consists of a metal underframe,



A Self-Propelled Convertible Freight Car

and continuous 2-in. grooved steel combination side posts and car lines extending from side sill to side sill with metal diagonal bracing. The outside and inside wall sheathing is of 1⅛-in. fir. The floor is of 1⅝-in. fir. The motor truck is forward. The air-brake system is arranged for "straight" operation on the motor car and "automatic" on trailers.

The main dimensions are:

Length over end sills	45 ft.
Length over platform	49 ft.
Length overall	52 ft. 8 in.
Width over side sills	9 ft. 8 in.
Width over sheathing	9 ft. 9⅝ in.
Width overall	10 ft. 4¾ in.
Width inside	9 ft. 2¾ in.
Length freight compartment	33 ft. 11¾ in.
Height, rail to roof	11 ft. 11 3/16 in.
Weight	56,000 lb.

An Appropriation of $100,000 for a Valuation of the property of the New York Telephone Co. by the Public Service Commission of the Second District (New York City) has been approved by Governor Glynn. The valuation will afford a basis for rate readjustment.

*From information furnished by the McKeon Motor Car Co., Omaha, Neb., builder of the car described.

Construction Difficulties with Stockton St. Tunnel, San Francisco

The chief engineering features of the Stockton St. tunnel in San Francisco were described in Engineering News, Feb. 12, 1914, p. 344. The contractors who are performing the work have encountered a serious problem in supporting the enormous weight of the shattered shales and schist traversed by the bore. Owing to the looseness of this material and to the necessary flatness of the arch, at certain locations a great proportion of the dead

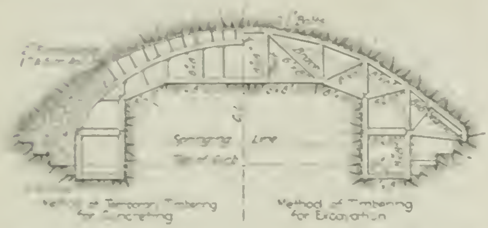


Fig. 1. Original Method of Timbering Stockton St. Tunnel, San Francisco

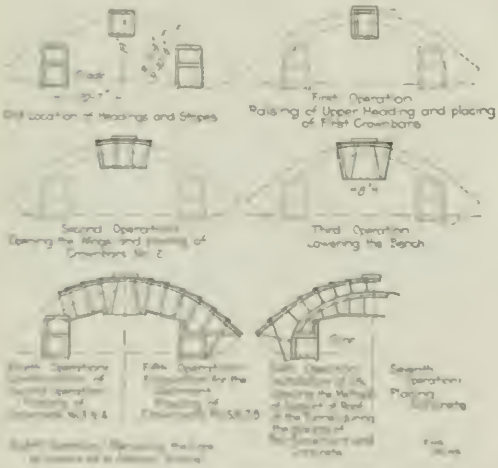

Fig. 2. Details of Progress of Later Method of Timbering Designed by L. F. [illegible]

weight of the material between the extrados and the ground surface must be supported by the falsework until the concrete lining is in place. The original plan of timbering is shown in Fig. 1. Near the portals this method was satisfactory, but when the central drifts had been advanced a distance of 130 ft. from the south portal a slide of loose, plastic material, which extended to the surface, temporarily blocked progress in the east drift.

After clearing the débris, instead of continuing to use the long [illegible] crown bars, the type of timbering illustrated in Fig. 2, proposed by L. F. [illegible], consulting engineer for the contractors, was adopted. This drawing shows each successive operation as followed in advancing the tunnel. So great was the stress to which the timbers were subjected that in one instance while performing the third operation the heavy longitudinal crown bars were crushed almost to failure. The hasty substitution of additional and larger timbers saved the section from failure.

A small portion of the tunnel is through sandstone, and in this formation the original concrete section was placed for the lining, wherever the formation was sufficiently solid to warrant its use. At other locations a modified and heavier section was substituted.

Fig. 3. View of Later Timbering

The present city engineer revised the plans and designed the thicker section. This resulted in an additional expenditure of $60,000 for 800 lin.ft. of tunnel lining. The new concrete lining is carrying the pressure successfully without any signs of settlement and makes this work monumental as the widest long span tunnel yet constructed.

New York City Ordinances for the Prevention of Sewer Explosions

The disastrous explosion at the Chelsea St. pumping station of the Metropolitan sewerage system in East Boston, Mass., June 1, again brings to the front the dangers resulting from gasoline and oils in sewers. With the universal use of gasoline motor vehicles, these explosions are increasing in frequency in every large city and must be stringently guarded against. Not only must laws be passed to prohibit the escape of gasoline and inflammable oils into sewers, but frequent investigations should be made of the sewer air in suspicious districts to make sure the law is being complied with.

New York City has had its share of explosions, but of late they have not been so frequent or so serious as they were a few years ago. The New York ordinances covering this point are given below:

EXTRACT FROM CODE OF ORDINANCES OF THE CITY OF NEW YORK

Section [illegible]. No connection with or opening into any sewer or drain in the City of New York, either public or private, shall be used for the conveyance or discharge, directly or indirectly, into said sewer or drain of any volatile inflammable liquid, gas or vapor, it being noted that a volatile inflammable liquid is any liquid that will emit an inflammable vapor at a temperature below 140° F.

Section 562. Every occupant of any premises which may be connected with a sewer or drain, public or private, who shall use or permit or allow to be used said sewer or drain for such purposes as hereinbefore specified in Section 1, and every owner of any premises who shall use, permit or allow the use of such sewer or drain for such purposes shall be deemed to have violated the provisions of this ordinance and be guilty of misdemeanor, and shall be punished upon conviction thereof by a fine of $50, or imprisonment for 30 days. (Ord. app. July 6, 1906).

EXTRACT FROM THE REGULATIONS OF THE MUNICIPAL EXPLOSIVES COMMISSION

Section 376. No garage permit authorizing the storage of volatile inflammable oil shall be issued for any premises which are not provided with an oil separator, trap or other similar apparatus attached to the house drain for the purpose of preventing volatile inflammable oils from flowing into the sewer; provided, however, that the Fire Commissioner may, upon the recommendation of the Municipal Explosives Commission, exempt from the requirements of this section a garage draining into a short sewer line.

Section 396. Each oil separator installed in a garage shall be connected to the house drain, and shall be so arranged as to separate all oils from the drainage of the garage.

A Continuous Reinforced-Concrete Girder Bridge for Interurban Cars

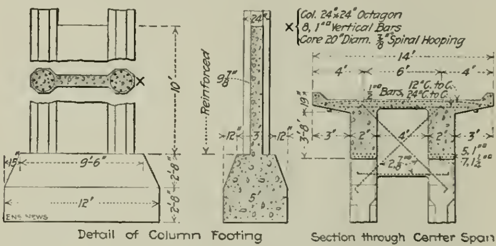
A reinforced-concrete girder bridge of simple details but effective design has recently been completed across White Rock Creek, about 6 miles outside of Dallas, Texas, for the Eastern Texas Traction Co., an interurban electric line to run between Dallas and Greenville. Fig. 1 shows the general details and Fig. 2 a view when it was nearly completed.

White Rock Creek has an intermittent flow; it is generally nearly dry, but at flood times reaches over a wide area of bottom lands. In addition, the railway crossing is within the back-water area of the White Rock Reservoir of the Dallas water-supply, so that ample provision had to be made for the water section. This consideration, together with the reduced cost due to simplicity of construction, led to the adoption of the girder bridge shown.

In brief, this bridge consists of three 50-ft. spans resting on two intermediate column bents and two twin-wall abutments. The roadway, for a single-track line, is a ballasted track laid on a solid concrete floor, continuous between abutments and forming a double T-beam with the girders, which in turn are monolithic with the bents and the abutments. There is no expansion joint in the structure, it being considered that it was strong enough to take all movement from end to end. The approaches are wooden trestles, with the end stringers resting on the abutments. The reinforcement of the superstructure is the normal rod system; the columns of the bents are reinforced by spirals.

Fig. 2. View of Bridge during Moderately High Water

The west abutment (right hand in Fig. 1) is founded on a satisfactory clay and the other abutment and piers on rock. Work was carried out by the company's forces, who, from inexperience in this type of work, had some trouble, but it is thought that for future similar bridges on the same line, better progress will be made. The bridge was designed by W. E. Beilharz, office engineer, under the direction of W. A. Obenchain, Chief Engineer of the company.



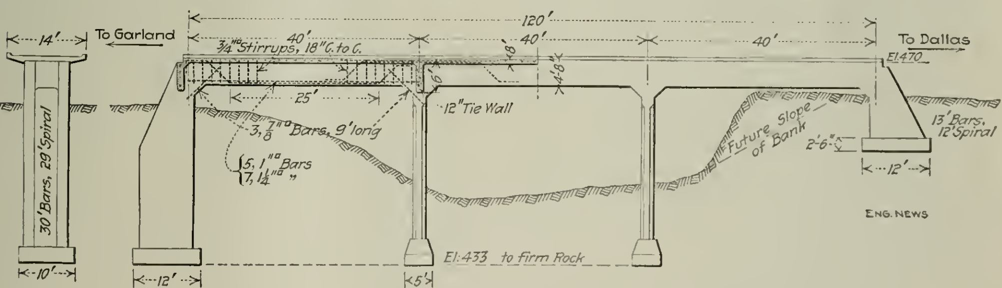


Fig. 1. Details of White Rock Creek Bridge, Eastern Texas Traction Co.

Road Improvement Work in Ohio during the present season will amount to about $15,000,000, according to a recent estimate of State Highway Commissioner James M. Marker. Of this sum $9,000,000 will be spent on contracts under the supervision of the State Highway Department and the remaining $6,000,000 directly by the counties and townships. About 320 miles of road are now being improved, 140 miles with macadam, and about 90 miles each with brick and concrete pavements. Since the organization of the State Highway Department in 1905 contracts have been let for the improvement of 67 miles of road. The only states which, it is claimed, surpass Ohio in the percentage of improved roads over all roads are Massachusetts, 19%, and Rhode Island, 49.1%, while Ohio has 34% of its highways improved.

Reducing the Per Capita Consumption of Water, Metropolitan District, Boston, Mass.*

The accompanying chart shows the remarkable results obtained by a systematic campaign to reduce the waste of city water in the Boston Metropolitan Water District. Of the 18 towns and cities using the water of the Metro-

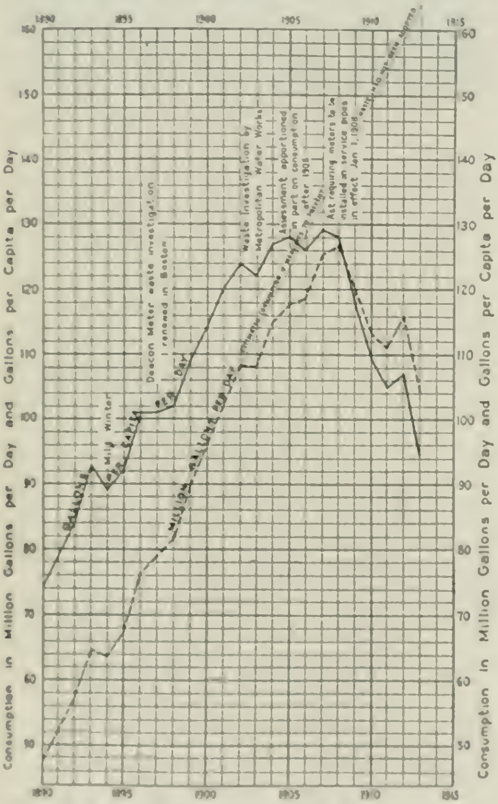

DIAGRAM SHOWING REDUCTION OF WATER CONSUMPTION IN THE METROPOLITAN WATER DISTRICT

politan Water District, has have practically all their services metered. Of the total of [illegible] services in [illegible] Dec. 31, 1913, [illegible] were metered. Had the per capita consumption continued at the rate at which it stood ten years ago, some [illegible] gal. per day more water would now be required and the Metropolitan Water Board would have spent and would be spending millions of dollars to develop new supplies.

Besides the service inspections, [illegible] every effort is made to detect and repair leaks in mains. To simplify this task there are now 77 Venturi meters connected with the works. Four of these are at the Wachusett Dam and are used in measuring water drawn from the Wachusett Reservoir. Two are located on the pipes leading from the Sudbury Dam and are used for measuring water drawn from the Sudbury Reservoir and delivered into the Weston Aqueduct. Sixty-five are on connections through which water is supplied to the different municipalities. There are also 3 Hersey disc meters, 1 Hersey torrent meter and 5 Hersey detector meters used in measuring small quantities which cannot be conveniently measured with meters of the Venturi type. The work of caring for these meters in the Metropolitan District has been done by two men, assisted at times by a third. The cost of the work connected with the reading, operating and maintaining of these meters has been $1,974.38.

*[illegible] Metropolitan Water and Sewerage Board, Boston, Mass.

Methods Used in Investigation of Explosive Gases and Oils in Sewers

By G. J. White*

City engineers are interested in the investigation of sewer explosions, yet perhaps but few of them have much knowledge of the methods used to determine whether the gas in a sewer is explosive or not, and if so, what makes it explosive. The purpose of this article is to give the average engineer, who is not a chemist, an outline of a method which may be used to determine if a sewer gas is explosive. A complete gas analysis is a long tedious process and if the gas is not explosive either alone or when mixed with air, the engineer has but little interest in it.

Gas Sampling

Gas-sampling pipettes (Fig. 1) of the mailing type (fitted in tin tubes or wooden boxes), may be purchased at a reasonable price and are convenient for handling. These should hold at least 300 c.c. to give a large sample to work on. An aspirator bottle (Fig. 2) holding a little more than the pipettes and a few feet of rubber tubing are necessary.

The pipettes should be filled with sewage which is saturated with the gas with which it is in contact. To do this fill the aspirator bottle with sewage, attach the rubber tube to the bottle and the lower nipple of the pipette; elevate the bottle above the pipette and open both cocks of the pipette, allowing the sewage to flow into the pipette by gravity. When the pipette is full, close both cocks, remove the rubber tube leading to the aspirator bottle and return the pipette to its case. As many pipettes as are necessary to secure the required number of samples may be thus prepared on the surface before entering the sewer.

The pipette is now taken into the sewer, to the point from which it is desired to secure a sample of the gas present, removed from its case and held in a vertical position with both cocks open. The sewage flowing out draws the gas in and when the sewage is all out, the pipette is full of gas. The stop cocks are now closed and the pipette returned to its case and the case marked for identification.

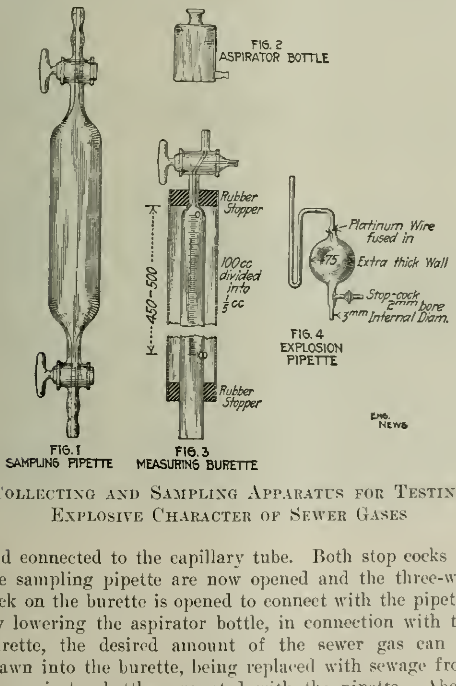
Examination in the Laboratory

For the examination in the laboratory, a water-jacketed [illegible] burette (Fig. 3) with a three-way cock

*[illegible] Department of Public Work, Detroit, Mich.

similar to a Hempel burette is necessary for the gas measurements. An explosion pipette (Fig. 4) connected up with two or three batteries and a good sparking coil is necessary for the explosion tests. The explosion pipette should be mounted in a wooden case with a sliding front of heavy plate glass in order that the operator may watch the explosion, yet be amply protected from harm in case of a too violent explosion.

The sampling pipette is removed from its case and mounted in a suitable holder in position to attach the capillary tube from the gas-measuring burette. The aspirator bottle is filled with sewage and placed on a shelf above the pipette, the end of the rubber tube being closed with a pinch cock. The rubber tube is now allowed to fill with water and slipped over the lower nipple of the pipette. The capillary connecting tube is attached to the burette with heavy rubber tubing and securely wired. The aspirator bottle connected with the gas-measuring burette is filled with sewage and the bottle raised, with the three-way cock open straight through, until water appears at the end of the capillary tube. The upper nipple of the pipette is now filled with sewage



Collecting and Sampling Apparatus for Testing Explosive Character of Sewer Gases

and connected to the capillary tube. Both stop cocks on the sampling pipette are now opened and the three-way cock on the burette is opened to connect with the pipette. By lowering the aspirator bottle, in connection with the burette, the desired amount of the sewer gas can be drawn into the burette, being replaced with sewage from the aspirator bottle connected with the pipette. About 25 c.c. of gas should be drawn over and allowed to stand three minutes (to allow water on the sides of the burette to run down), before measurement. In the meanwhile the cocks on the pipette are closed, the pipette removed from its holder, returned to the case and the explosion pipette connected to the capillary tube. The three-way cock is now turned to connect through from the explosion pipette to the air, the stop cock on the explosion pipette opened, the aspirator bottle filled with mercury raised to allow the explosion pipette to fill with mercury. A cushion (about ½ in.) of water should be carried on top of the mercury in the explosion pipette. When the explosion pipette is full and water appears at the three-way cock, the cock is turned to connect through from the burette to the explosion pipette, the mercury bottle lowered and the sample of gas drawn into the explosion pipette. When the gas is all over, the three-way cock is closed and a pinch clip is placed on the rubber tubing connecting the capillary tube to the explosion pipette—to protect the gas-measuring burette in case of a too violent explosion. The mercury bottle is now raised to the level of the mercury in the explosion pipette and the stop cock closed. The gas sample is now confined in the explosion pipette over mercury and at atmospheric pressure. The switch connected with the batteries is then closed for a moment, passing an electric spark through the gas. If the gas is explosive, the operator will see a flash of flame through the gas. If the gas is not explosive in its original condition, it may only need oxygen to make it explosive: so it is passed back to the gas-measuring burette, the capillary tube disconnected and equal parts of air drawn into the burette. After measurement the mixture is passed into the explosion pipette and a spark sent through it. Various mixtures of the gas and air, under various conditions of pressure may be passed into the explosion pipette and sparked. If it is found that the sewer gas cannot be exploded alone or when mixed with air, then measured amounts of city gas from a gas tap may be added to find the amount needed to make the sewer gas explosive.

If it is desired to measure the relative intensity of the explosion of various gas mixtures, a sensitive recording gas-pressure gage may be connected in series with the explosion pipette and the mercury bottle and the blow of the explosion thrown directly onto the recording chart. While this method will not give absolute measurements of the intensity of the explosions, it will give relative measurements which are of value.

If it is found that the sewer gas is not explosive alone or when mixed with air, the engineer is no longer interested in it. If it is found to be explosive, then the remainder of the sample in the sampling pipette should be sent to an experienced gas analyst for analysis to determine what makes it explosive.

Examination of Sewage for Oil

At least ten liter samples of the sewage should be obtained in bottles with a small neck. Two or three pounds of common salt (NaCl) are added to the sewage to make a fully saturated brine and the bottles are allowed to stand at least 24 hr. The salt increases the density of the solution and hastens and makes more complete the separation of the oil. After standing a sufficient length of time, the oil is siphoned off the top (preferably with a vacuum pump) into a distilling flask with a side-arm outlet. It is impossible to prevent some of the water coming over with the oil, so the flask is now connected with a Leibig condenser and the oil distilled off at 205° F. This will give a fairly good separation of the oil from the sewage and does not necessitate the distilling of the entire sample. If it is desired the oil may be redistilled and fractionated to determine the boiling point of the various fractions. A Westphal balance or hydrometer may be used to determine the specific gravity of the fractions for further identification.

Two Interesting Bridges on the El Paso & Southwestern Ry.

The bridges on the El Paso & Southwestern line between Fairbanks and Tucson, Ariz., include a riveted-truss bridge in which the trusses have no counters, and a plate-girder bridge with three-post towers which are triangular in plan. The other structures are mainly concrete arches and concrete slab-deck trestles. The bridges are designed for Cooper's E-55 loading. J. L. Campbell is engineer of the railway.

Bridge Trusses without Counters

Near Irene, Ariz., the line crosses the Southern Pacific Ry. and the cañon of Cienega Creek by a bridge having two riveted-truss deck spans of 168 ft., with a single 50-ft. plate-girder span (65 in. deep) at one end and two 75-ft. plate-girder spans (85 in. deep) at the other end. This bridge is shown in Figs. 1 and 2. The assumed dead-load for the truss spans is 2100 lb. for the trusses, 600 lb. for the floor and 500 lb. for the track, or 3200 lb. per lin.ft. of bridge; for the girder spans it is 1100 lb. and 800 lb. for steel and 500 lb. for track, making 1600 and 1300 lb. for the 75-ft. and 50-ft. spans, respectively.

The trusses are of the parallel-chord Pratt type, with vertical end posts. They are 23 ft. 9 in. deep, and have a panel length of 23 ft. 9 in., the length c. to c. of end pins being 166 ft. 3 in. The expansion bearings are on the middle pier and the fixed shoe bearings on the end piers. The trusses are spaced 15 ft. c. to c., and have plate-girder floorbeams riveted between the posts. The floorbeam at the outer end of each span is 60 in. deep, all the others are 46 in. deep. Upon the floorbeams are two lines of 38-in. plate-girder stringers 7 ft. 6 in. apart, which carry ties 10x10 in., 10 ft. long, boxed out $\frac{1}{2}$ in. over the flanges and carrying guard timbers 6x8 in., which are boxed out 1 in. over the ties. Each third tie is secured to the stringers by $\frac{3}{4}$-in. hook-bolts which pass through the guard timbers.

The top chords of the trusses are of trough section, with two 22-in. web plates (16 in. apart), four outside flange angles 4x4 in., and a top cover-plate 26x$\frac{5}{8}$ in., while double lacing is riveted across the lower flanges. The bottom chords are similar, but with double lacing top and bottom, and in the three middle panels the 22-in. web-plates are reinforced by outside 13-in. plates. The vertical end posts are of similar section to the top chord, with the addition of an interior transverse diaphragm or web-plate secured to the side plates by four angles. The

Fig. 1. Bridge with Riveted Truss Spans of 166 Ft. 3 In., across Cienega Creek; El Paso & Southwestern Ry.

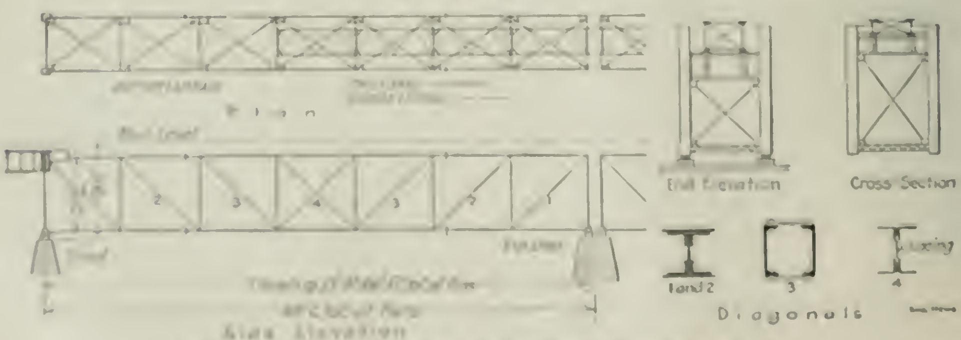


Fig. 2. Riveted Deck Truss Spans for Cienega Creek Bridge

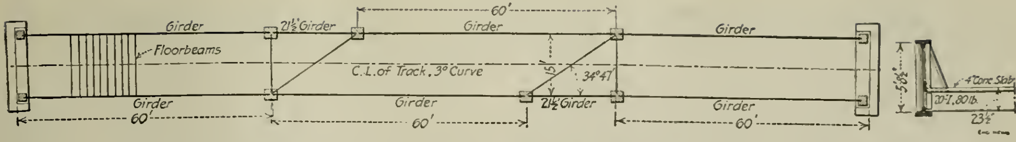

FIG. 3. THREE-SPAN PLATE-GIRDER BRIDGE WITH THREE-POST TOWERS; EL PASO & SOUTHWESTERN, RY.

shoe pins are 8 in. The intermediate posts are of box section, built up of plates and angles or of a pair of channels (with flanges inward).

The diagonals in the first two panels at each end are of H-section (three plates and four angles), while those of the next panels are composed of two 15-in. channels with flanges inward. In the middle panel, each diagonal is of four angles and transverse web lacing, with two connection plates 45 in. square at the intersection. All connection plates are large, to provide for ample riveting.

BRIDGE WITH THREE-POST TOWERS

At Mescal, Ariz., the line again crosses over the Southern Pacific Ry. It is carried by a through plate-girder bridge having three 60-ft. spans, and the angle of skew (34° 47′) led to the use of the three-post pier arrangement shown in Fig. 3. Each tower has one 21½-ft. girder to fill in between the two 60-ft. girders, and is braced on all three sides. A view of this bridge is shown in Fig. 4.

Each column is composed of a pair of 15-in. channels (with flanges inward), a diaphragm or web-plate 15x⅜ in., and four angles 5x3½ in., connecting the web to the channels. The open sides have no bracing or batten plates. The shoe rests on a concrete pedestal and the top has a ½-in. cap plate 25x25 in., secured to the column by four angles 4x6 in. The struts, braces and hangers are pairs of angles with lacing or batten plates over the flanges. The hangers are used only on the two longer sides of the tower.

The 60-ft. girders have ½-in. web-plates 68½ in. deep, four flange angles 8x8 in., and cover-plates 20x$\frac{9}{16}$ in. They were made in half lengths and spliced in the field. The 21½-ft. girders have the same web-plates, with flange angles 6x4 in., and no cover-plates. A solid floor is used, so that the ordinary ballasted track is carried across the bridge. The floor consists of 20-in. transverse I-beams resting on the inner flange angles and secured to the girders by angle connection plates. Over these beams is laid a 4-in. concrete deck, which is sloped up against the girder web on each side. This construction is shown in Fig. 3.

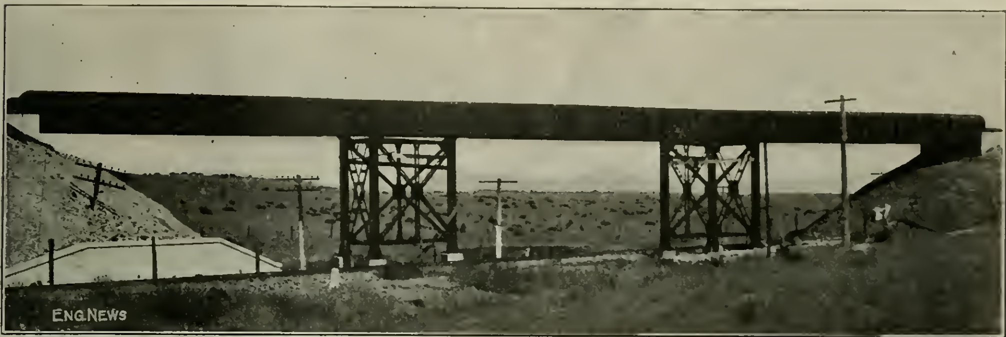

FIG. 4. PLATE-GIRDER BRIDGE WITH THREE-POST TOWERS

Dust on Underground Railways in Paris has been investigated owing to the condition of the air in the tunnels of the Metropolitan line being much worse than in those of the North-South line. It is found that the former contains 134 milligrams of dust per c.c. as against only 6 to 16 milligrams in the latter. The principal cause (on the Metropolitan) appears to be in the rails, which are of relatively soft steel, and in the braking, the brakeshoes being of cast iron. On the North-South line, the rails are of harder steel and the brakeshoes are faced with a tar-treated fabric, which reduces wear and noise. Another cause is in the car-floor construction, the cars of the former line being of wood with narrow wearing strips which make it difficult to clean the floor. On the latter line the floor is covered with a composition which gives a smooth and uniform surface that is readily cleaned with wet sawdust. Another proposed plan, as noted in "The Engineer" (London) is to cover the ballast with tiles at the stations, so that the track can be cleaned and the dust removed.

A Reinforced-Concrete Pier Damaged—What appears to be a serious imperfection in the concrete jetty erected by the Gladstone Harbor Board, Queensland, has been noted by E. A. E. Cullen, Engineer for Harbors and Rivers, who has recommended that the necessary repairs be undertaken forthwith. Mr. Cullen, who inspected the jetty, submitted a report as follows: "It is a matter of great disappointment to find that a reinforced-concrete wharf may require a periodic maintenance, as it was hoped that such would not be the case, except for surface wear and tear. What has occurred at Gladstone is that the concrete in the beams has not proved impervious to the water everywhere, and in consequence moisture has in places reached the steel reinforcing bars, causing corrosion. The expansion of the rust caused cracks in the concrete. Another factor which may have produced cracks, permitting moisture to enter, is the severe punishment the jetty receives at times from the impact of steamers. To repair the structure it will be necessary to cut away the damaged concrete, clean any rust off the bars, and restore with fresh mortar. It is very difficult to estimate the cost of such work. Probably it will not exceed £250. The structure was completed in 1908, and showed no visible deterioration until recently, save for a few rust spots in places where the steel had been insufficiently covered with mortar. These were cut out and restored in November, 1912."—"The Commonwealth Engineer," Melbourne, Australia.

A Novel Flexible Locomotive

SYNOPSIS—Several types of locomotives with flexible wheelbase have been designed for railways having numerous and sharp curves, and where the limiting conditions of power and axle load necessitate distributing the load over several axles and a considerable total length of wheelbase. The general principle of these is to mount the engine on groups of wheels, some or all of which are carried in swiveling trucks, while the wheels of each group are driven directly or by gearing. The accompanying article describes an English design of flexible locomotive which is in use on a number of railways, and which has the peculiar feature of carrying the boiler suspended between the trucks.

⁂

The Garratt type of flexible locomotive, now in use on some foreign railways, has the boiler mounted on a girder frame whose ends are pivoted upon two steam trucks, there being no wheels under the boiler. This is the distinctive feature which differentiates it from all other flexible locomotives (articulated or otherwise), as noted in a brief description in our issue of Apr. 13, 1911. Fig. 1 shows a freight locomotive of this type for the Tasmanian Government Railways. It will be seen that the engine consists of three separate and distinct units: the boiler with its girder frame, and the two steam trucks or driving trucks. The pivots or king-pins forming the attachments of the boiler frame to the trucks are near the inner ends of the trucks (or nearly over the inner driving axles), and the requisite weight on the forward part of each truck is supplied by a water tank.

In the Fairlie and Mallet engines the wheels are divided into two groups, each with its own cylinders, but all the wheels are placed beneath the boiler. The Fairlie engine has two swiveling trucks, while the Mallet engine has the rear group carried in rigid frames and the leading group carried in a swiveling truck having a pin-jointed connection at the rear end. In furnishing us with information as to the newer type of engine, the inventor calls attention to some points in comparing the Garratt type with the Fairlie and Mallet types, especially the greater possible sizes of boilers and wheels under like conditions of gage, and the relative stability of the three types.

In the Garratt type, as the wheels are not under the boiler, both they and the boiler may be of any size that will pass through the clearance limits. In the Mallet and Fairlie types the wheels are under the boiler, and therefore limit each other. Mr. Garratt thinks it would be difficult to build a high-speed engine on these designs, because, if the wheels are to be of suitable diameter for fast running, there would not be room for a large boiler and firebox of sufficient capacity. However, Mallet engines with 73-in. wheels and weighing 188 tons are in use in passenger service on the Atchison, Topeka & Santa Fe Ry. They are of the 4:4:0—0:6:2 type, and operate on grades of 1.75% with curves of 16°.

It is claimed that in the Garratt arrangement the trucks swing more freely and follow the curves with less resistance than in engines having the trucks under the boiler. As the boiler frame does not extend beyond the truck centers, when the engine is on a curve there are no overhanging ends of the frame of the boiler (tangential to the curve) to reduce the stability. With regard to stability, Fig. 3 shows three types of flexible engines on the same curve, the Mallet engine being shown

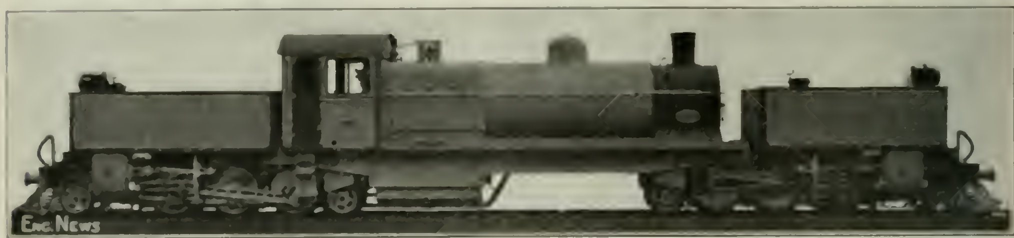

FIG. 1. FREIGHT LOCOMOTIVE OF THE GARRATT FLEXIBLE TYPE; TASMANIAN GOVERNMENT RAILWAYS

without its tender and the other two being tank or self-contained engines. The portions shaded black indicate weight displacement unfavorable to stability, and the cross-hatched portions indicate weight increasing the stability. It is noted that in the Garratt engine, the sharper the curve the greater the favorable displacement of weight, while in the Mallet and Fairlie types, the unfavorable condition increases as the curve becomes sharper.

Further, as the rear-wheel system of the Mallet type is rigid, the center line of the engine is tangential to the curve, as from the center of the rear-wheel system, thus throwing greater weight on the outer leading wheels, which at high speeds, may exceed the official fixed maximum weight. The engine described is the invention of

(Each truck has four cylinders.)

Herbert W. Garratt, 9 Ellerker Gardens, Richmond (Surrey), England, and is built by Beyer, Peacock & Co., locomotive builders, Gorton Foundry, Manchester, England. For information regarding it we are indebted to Mr. Garratt and the builders.

Garratt Locomotives for the Tasmanian Government Railways

A Garratt freight locomotive for the Tasmanian Government Railway is shown in Fig. 1, while Fig. 2 shows one of the steam trucks for a passenger engine for the same railways. In the former, each steam truck is of the 2:6:2 type, with six driving wheels, while in the latter each truck is of the 4:4:2 type, with four driving wheels. They are for service on the main lines (3-ft. 6-in. gage), where the maximum grades are 2.5% (up to 6½ miles long) with curves as sharp as 17°.

The passenger engine has four cylinders to each truck, 60-in. driving wheels with 6-ft. rigid wheelbase, and a maximum axle load of 12 tons. It is designed for a maximum speed of 55 mi.p.h., and to haul a train load of 200 tons at 30 mi.p.h. on the maximum grade with 17° reverse curves. The freight engine has two cylinders to each truck, 42-in. driving wheels with 8-ft. rigid wheelbase, and a maximum axle load of 9½ tons. Its tractive force, at 75% boiler pressure, is 28,284 lb. The boilers are alike and the parts of the two engines are made interchangeable as far as possible. The ordinary engines used in the same service are 4:4:0 passenger engines(which haul 100-ton trains), and 2:6:0 and 4:6:0 freight engines, all having tenders.

The absence of side tanks and of wheels beneath the boiler permitted the use of a barrel of large diameter and moderate length, with a wide and deep firebox of the Belpaire type. The grates are designed for burning the inferior native coal, but provision has been made for using oil fuel, in view of the development of oil wells in Tasmania. The boiler is of steel, with copper firebox, steel tubes and a 24-tube Schmidt superheater. The steam pipes have ball joints directly over the king-pin pivots. The exhaust from the two groups of cylinders is led to a double exhaust nozzle in the smokebox, having a central opening for the forward cylinders and an annular opening for the rear cylinders.

In the passenger engine, the driving and rear axles of each steam truck are equalized. The four cylinders drive the first driving axle (which is of nickel-chrome steel), the inside and outside cranks being placed at

Capacity of coal bunkers		4 tons	2 tons	

* 1220 gal. on front truck.

180°. The Walschaerts valve gear is used, with screw reversing gear. The inner carrying axle of each group has a lateral play of ¾ in. The water tanks are connected by equilibrium pipes, with flexible connections, and the coal bunkers have inclined bottoms so as to feed the coal to the deck by gravity. Steam and vacuum brakes are applied to all driving wheels, while the truck at the firebox end has also a hand-brake for the coupled wheels. A steam sanding apparatus is applied, and the engine has an electric headlight and a speed indicator.

In the freight engine, the front truck and first driving axle of each group are equalized, while the second and third (main) driving axles and inner carrying or pony-truck axle form a separate equalizing system. This engine has an acetylene gas headlight. A satisfactory distribution of weight is secured, so that even with both bunkers and tanks empty (which condition would not exist in service) there is ample weight on the pony truck axles. The general dimensions of these two engines are given in the accompanying table.

The first Garratt engines used on the Tasmanian lines were for the Northeast Dundas branch, of 2-ft. gage, having maximum grades of 4%, and sharpest curves of 99-ft. radius. Each engine had two four-wheel trucks (with the cylinders at the inner ends), and weighed 33 tons complete. The ordinary engines on this branch were tank engines of the [illegible] type.

THE GARRATT LOCOMOTIVE ON OTHER RAILWAYS

Six locomotives of this type were built in 1911 for the Western Australian Government Railways (3-ft. 6-in. gage), and they proved so satisfactory that six additional locomotives (equipped with superheaters) were ordered and were delivered in 1913. Each truck has a 2:6:0 wheel arrangement, with [illegible] for the boiler frame between the second and third driving axles. These engines were designed to [illegible] grades of [illegible] with curves of 17°, and the axle load was limited to 8 tons. The dimensions of the engines are given in the accompanying table.

In addition to the Tasmanian and Australian railways noted, locomotives of the Garratt type have been built for the Darjeeling-Himalayan Ry., in India; the Arakan Flotilla Co., of Burma; the San Paulo Ry. and Mogyana Ry., of Brazil, and the Belgian-Congo Ry., of Africa. The Darjeeling Ry. (24-in. gage) is noted for its steep grades and its extremely sinuous location, including several loops. The engines have two four-wheel trucks (0:4:0—0:4:0), with the cylinders at the outer ends; they weigh 28 tons, and can traverse reverse curves of 60-ft. radius. The Congo Ry. engine (30-in. gage) has six-wheel trucks (0:6:0—0:6:0), with cylinders at the extreme outer ends connected to the inner driving axles. Oil fuel is used, carried in a cylindrical tank on the forward truck. The engine was built by the Société de St. Léonard, at Liége, Belgium, and was shown at the international exhibition at Ghent in 1913.

Designs have been made for a large standard-gage engine of the 0:8:0—0:8:0 class, with eight driving axles.

A Special Rail Section for Curves

An interesting development in railway-track construction is a so-called "frictionless" rail designed to be used on the inside of curves. Its special feature is a very narrow head, and its purpose is to reduce the slip of the inside wheel, which takes place in compensating for the greater length of travel of the wheel on the outside rail. It is claimed that there is a diminution of friction and resultant wear to both the outer and inner (frictionless) rails and the wheel flanges; while the reduced friction gives a freer and smoother passage of the wheels, with a reduction in power required to handle a given tonnage. The rail is supplied by the Frictionless Rail Co., of Boston, Mass.

Other special rails for curves have been designed mainly to give additional metal available for wear. The Manning rail, tried some years ago on the Baltimore & Ohio R.R., had $\frac{3}{32}$ in. of additional metal on the inner side of the head and $\frac{3}{32}$ in. less on the outer side. The special 110-lb. rail of the Lehigh Valley R.R. (ENGINEERING NEWS, Oct. 24, 1912) has the head slightly wider and considerably deeper than that of the standard rail.

SOUTHERN PACIFIC RY.

The Southern Pacific Ry. has ordered 5000 tons of the frictionless rail, using a 90-lb. section as a companion to the standard 90-lb. A. R. A. (A) type section, and for information as to this we are indebted to John D. Isaacs, Consulting Engineer, Southern Pacific Co. The rail is laid on 9° and 10° curves on single track, carrying heavy traffic. The track has 18 ties 7x9 in. to a 33-ft. rail length, the ties having tieplates and being laid in a full bed of ballast. The rails are laid with suspended joints, 18 in. c. to c. of ties, and are spliced with [illegible] bars, having four bolts ([illegible] in. c. to c.) with heads alternately on the inside and outside of the rail. This is the standard joint construction.

The rail has not been in service for a sufficient time to enable a definite statement to be made as to its performance, but we are informed that so far the reports are satisfactory. The sections of the standard and frictionless rail are shown in Fig. 1, while Fig. 2 shows the

taper rail for connecting the two sections at the ends of the curves. The dimensions are shown in the accompanying table:

Boston Elevated Railway

On the Boston Elevated Ry., the frictionless rail has been laid on several curves, ranging from 9° to 57°, the length of rail used being from 116 to 482 ft. The rail weighs 79½ lb. per yd. and is used with the 85-lb. Am. Soc. C. E. section. Both are of openhearth steel, treated with ferro-titanium, with chemical composition as follows: carbon, 0.80 to 0.95%; phosphorus, under 0.04%; silicon, 0.10 to 0.20%; manganese, 0.65 to 0.90%; metallic titanium, 0.10%; sulphur, 0.03 to 0.05%. For information as to the service we are indebted to H. M. Stewart, Chief Engineer of Maintenance-of-Way.

On account of the short length of these curves it has not been possible to obtain accurate tests as to the increase or decrease in power consumption used by a train in going around the curves, but it is known that less power is required than when the curves were laid with the 85-lb. rail. In some instances where power was required to pass a curve laid with the 85-lb. rail, it is now possible to coast through the curve. It is not found that the narrow-headed rail decreases the braking power of the trains. Practically all of the special rail is on the elevated structure where it is considered necessary to use a heavy guard rail, rigidly attached to the inner rail of the curve. Therefore, the results on this road may not conform with those obtained on steam roads where guard rails are not used.

As an example of the experience with this rail, the curve at Causeway and Haverhill St. may be taken. This has a radius of 90 ft. on the center line, and about 297 ft. of the frictionless rail was laid on the inside of the curve in 1912. The conditions on this curve have been as follows:

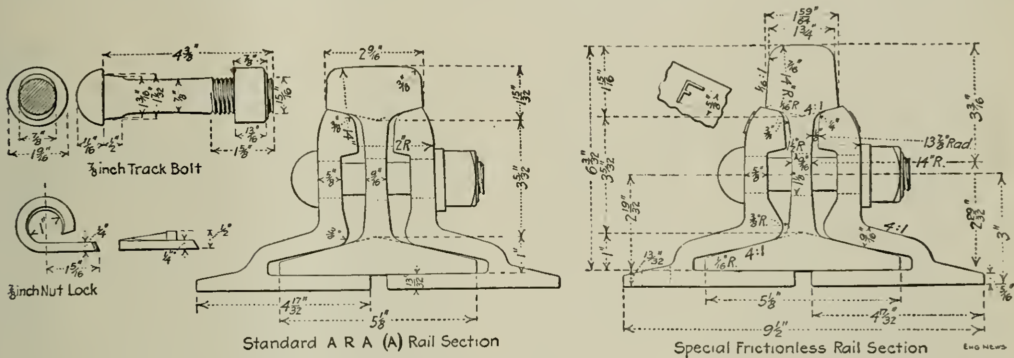

Fig. 1. Comparative Sections of the Standard 90-Lb. Rail and the Special "Frictionless" 90.29-Lb. Rail Used on the Inside of Sharp Curves; Southern Pacific Ry.

On the inside of the curve, the 85-lb. Am. Soc. C. E. rails of openhearth ferro-titanium steel were removed Nov. 16, 1912, after a life of 262 days, with a wear of 0.029 ft., being removed on account of corrugations. The 79-lb. "frictionless" rails of the same steel, laid on the above date, were examined on Aug. 26, 1913, after 283 days' service. The wear was 0.036 ft., while there was very little corrugation. The permissible amount of wear is 0.015 ft., and the life of this rail therefore was estimated at 351 days, or 35% more than the actual life of the former ordinary rails.

On the outside of the curve, the 85-lb. rail showed a wear of 0.039 ft. during the 262 days' life of the 85-lb. ordinary rail on the inside, while it was 0.040 ft. during the 283 days' service of the 79-lb. special rail.

The Wheeler Filter Bottom

By Robert Spurr Weston*

It has been clearly demonstrated by J. W. Ellms† at Cincinnati that the sand beds of mechanical filters can be most effectively cleaned by the application of wash-water at rates exceeding a vertical velocity, above the sand, of 8 mm. per second (18 in. per min.). Other engineers have confirmed the truth of Mr. Ellms' observations. Where lower velocities have been used, it has been necessary to agitate the sand during washing by means of revolving rakes, compressed air or other devices.

To make use of the higher velocities of wash-water, it has been the practice either to deepen the whole gravel layer of the filter or to hold in place the lower coarse layer (that immediately above the wash-water inlets) by means of suitable screens. When the bottoms of such filters consist of a series of troughs or inverted pyramids, the screens cover the depressions, but where a flat bottom is used special standards have to be provided. All of these arrangements are expensive and not in all cases satisfactory.

The disadvantages of existing arrangements led William Wheeler,‡ on June 29, 1907, to design an improved filter bottom. At that time his idea was to use it in connection with a filter plant in Kentucky. This work, however, was postponed and the device was not worked out until 1913, when the writer and his assistants experimented with it and later embodied it in the design of the filters at Belfast, Maine, recently put into operation.

Mr. Wheeler's original design (Fig. 1) consisted of a series of concrete inverted pyramids, spaced 1 ft. c. to c. At the bottom of each pyramid is a 0.75-in. tube which serves both as filter outlet and wash-water inlet. There is nothing particularly novel in the so called hopper bottom; it has been used in water filters for many years, notably at the plant of the Hackensack Water Co., at Milford, N. J.§

Hitherto all filter bottoms with depressions, pyramidal or prismoidal, have been provided with strainers of some sort and have been filled either with uniform or ununiform material placed at random—for example, shot, quartz, gravel, rods, etc. The Wheeler filter bottom obviates [illegible] the objections to previous designs and differs from them in that it substitutes for a wash-water distributing layer placed at random, an assembly of distributing elements in the form of true spheres of cement, earthenware or other suitable material. In other words, it substitutes for a random layer a system of spheres arranged according to definite mechanical principles. These make use of the adhesive force between the water on the one hand and the spheres and the slopes of the inverted pyramids on the other, effecting a nearly perfect distribution of wash-water, so that it leaves the tops of the pyramids with a nearly uniform vertical velocity. It does this without allowing any of the sand to work down into the voids between the spheres, and at the same time it renders available substantially the entire top of the depressions to collect and discharge the filtered water.

The ball nozzle is an example of the action of the sphere on the jets issuing from the bottom of each pyramid during washing. It is a well known fact that a solid sphere is the geometrical form having the greatest weight in proportion to its surface. Therefore, it presents a form which has the greatest weight with the least surface friction. The form and the surface of the spheres, therefore, makes them least liable to disturbance by the upward flowing stream of wash-water. In fact, they will not move with wash-water velocities of less than 25 mm. per sec. (5 ft. per min.) even when uncovered with gravel. This immobility of the spheres allows the use of very thin gravel layers to support the

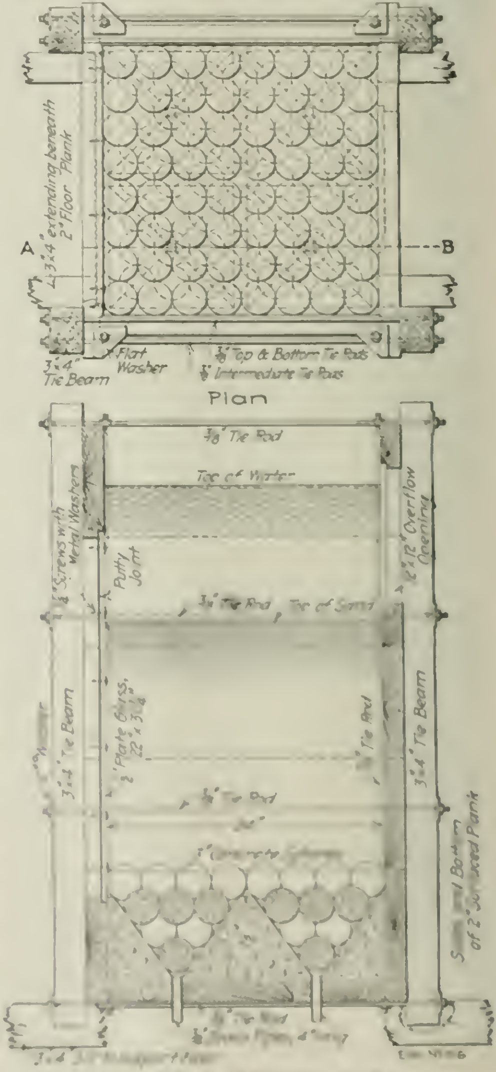

FIG. 1. WHEELER FILTER BOTTOM IN CONCRETE EXPERIMENTAL FILTER

§"Engineering Record," Vol. 50, p. 672.

sand layer—thereby reducing the thickness of the underdrain system and the cost of construction.

Design of the Filter Bottom

Mr. Wheeler's original design was as follows: Directly over each wash-water inlet was placed a 3-in. sphere molded of Portland cement; over the first sphere were placed four others; over these four, nine; and over these nine, twelve more—making a system of 30 spheres arranged like an inverted pile of cannon balls.

Experiments showed that this first design was unnecessarily refined. Accordingly, the number of 3-in. balls was reduced from 30 to 5, and above these were placed nine glazed, earthenware marbles, eight of which had a diameter of 32 mm., and one (the center one) a diameter of 40 mm. Above this system of spheres were placed three layers of gravel. These layers may be surprisingly thin without allowing any of the sand to escape during filtering or any mixing of it with the gravel during washing. In the plants in practice a layer 6 in. in thickness has been used, but the writer feels reasonably sure that a 3-in. layer would satisfy all requirements, so good is the distribution of wash-water and the grading of the gravel layer. The inverted pyramids are truncated and their sides do not meet to form a sharp edge.

Experiments—Preliminary to designing the new filters for the Belfast (Maine) Water Co., Mr. Wheeler and the writer conducted a series of experiments at Concord, Mass., with a small observation filter.

Filter—The filter is practically that shown in Fig. 1. It had an area of cross-section of 4 sq.ft. and four 3/4-in. effluent tubes were connected by means of reducing fittings and 1½-in. pipes with an adapter, the latter connecting with the 2½-in. hose to the hydrant. With this arrangement it was possible to maintain a vertical velocity of 25.2 mm. per sec., equivalent to about 5 ft. per min.

Sand—Five different kinds of sand were used. Two, from Concord, Mass., were bank sands, and three were beach sands from the Massachusetts coast. The results of mechanical analyses of samples of these sands, taken after they had been in use, are shown in Table I.

TABLE I. MECHANICAL ANALYSES OF FILTER SANDS

Sand No	Kind	Lab. No.	10% finer than	60% finer than	Uniformity coefficient
1	Concord	348	0.49	0.94	1.92
2	Concord	355	0.33	0.47	1.42
3	Plum Island	363	0.53	0.79	1.49
4	Salisbury Beach	370	0.40	0.60	1.50
5	Ipswich	377	0.26	0.44	1.69

Gravels—Three grades of gravel were used to support the sand. This gravel was screened from Concord sand No. 1 and separated into three grades, first that passing a coarse screen having 1 in. square meshes and retained on one having 3/8-in. square meshes, second that passing through a screen having 3/8-in. square meshes and retained on one having 1/4-in square meshes, and third that passing through a screen having 1/4-in. square meshes and retained on one having 12 meshes per lin.in. Two of these gravels were subjected to mechanical analysis (see Table II).

TABLE II. MECHANICAL ANALYSES OF FILTER GRAVEL

Sample	Lab. No.	10% finer than	60% finer than	Uniformity coefficient
Medium	383	12.5	18.0	1.41
Fine	384	2.36	2.60	1.10

Cement Balls—The 3-in. cement balls used to fill the pyramids were made in the laboratory from neat Portland cement. Their specific gravity was 2.4.

Marbles—The marbles used to fill the interstices between the cement balls were ordinary German, blue agate marbles—that is, cheap glazed earthen ware. They averaged 1.2 in. in diameter, and had a specific gravity of 2.84.

Trials

Trial No. 1—The first trial was made with each pyramid filled with four layers of concrete balls, that is, 30 balls to a pyramid. The interstices between the balls at the surface were filled with 25 marbles.

Water was applied to this system of balls and marbles at the rate of 25 mm. per sec. without disturbing the position of the marbles.

Trial No. 2—In this trial the upper layer of balls was removed, leaving the first 14 balls in each pyramid arranged in three layers. These balls could not be displaced with the velocity available, and 16 marbles were placed in the interstices at the surface. Table III gives the results of observations at different velocities:

TABLE III. RESULTS OF TRIAL NO. 2 WITH THREE LAYERS OF BALLS, AND ONE LAYER OF MARBLES, AND WITH AND WITHOUT GRAVEL LAYERS

System	Vertical velocity mm. per sec.	Vertical velocity ft. per min.	Results
A—Balls and marbles only.	8.0	1.6	No movement
	20.0	4.0	No movement
	21.8	4.3	No movement
	22.6	4.4	Marbles revolve
	23.5	4.6	Marbles revolve
B—Like A with 2 in. of ⅜ to 1 in. gravel. Level of gravel was 1 in. above tops of balls.	12.7	2.5	No movement
	24.4	4.8	No movement
	24.6	4.8	No movement
C—Like A with 1 in. of ⅜ to 1 in. gravel, 1.5 of ¼ to ⅜ in. gravel.	24.6	4.8	No movement
D—Like A with 0.3 ft. of graded gravel.	20.0	4.0	No movement
	24.6	4.8	No movement

Trial No. 3—Trial No. 3 was similar to Trial No. 2, with the exception that fine gravel of two different thicknesses, namely 0.1 and 0.3 ft., was placed above the coarser graded gravel.

When the finer layer (*A*) was used, most of the movement took place around the periphery of the filter and at the corners of the pyramids. The lift or boiling in the center of each pyramid was less than around the periphery but was in spots, and always in the same spots. With velocities below 18 mm. per sec., equivalent to 3.5 ft. per min., the fine gravel was undisturbed. With higher velocities there was a slight movement.

With the thick layer of fine gravel, the surface was lifted at two spots from 0.2 to 0.3 ft. above its average elevation.

The results are summarized in Table IV (p. 24).

Trial No. 4—Trial No. 4 was made with two layers of balls and one layer of marbles; that is, four marbles and nine balls in each pyramid. In addition to the balls, gravel layers of various thicknesses were tried.

It will be noticed that when balls and marbles alone (*A*) were used, a velocity of 10.7 mm. per sec. caused the corner marbles to revolve slowly. When the velocity was increased to 16 mm. per sec., the side marbles revolved; the corner marbles were lifted one-half way to the top of the pyramid, while the center marble remained stationary. When the velocity was increased to 17.9 mm. per sec., a large percentage of the corner marbles was lifted nearly to the top of the pyramid and all of the marbles except the center ones were moved.

TABLE IV. RESULTS OF TRIAL NO. 3 WITH THREE LAYERS OF BALLS, ONE OF MARBLES AND VARIOUS GRAVEL LAYERS

System	Vertical velocity mm. per sec.	Vertical velocity ft. per min.	Results
A—With 0.3 ft. graded gravel and 0.1 ft. fine gravel	12.7	2.5	No movement
	16.9	3.3	No movement
	17.9	3.5	No movement
	20.3	4.0	Slight movement at edges
	21.8	4.3	Slight boiling
	22.0	4.3	Boils and expands 0.5 in.
	23.5	4.6	Boils and expands 0.5 in.

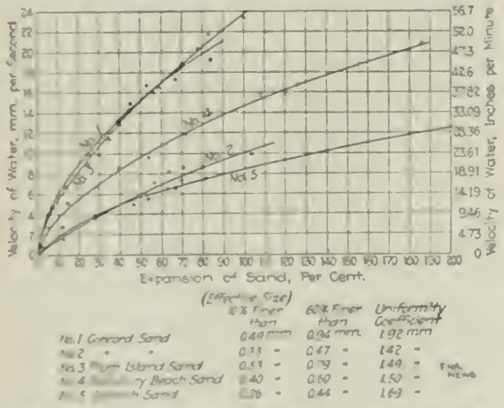

FIG. 2. RELATION BETWEEN UPWARD VELOCITY OF WASH WATER AND EXPANSION OF SAND IN MECHANICAL FILTERS

With the highest velocity, 25 mm. per sec., the action was similar to that observed at a lower velocity. A larger percentage of the particles, however, was lifted to the tops of the pyramids. With the velocities available none of the marbles could be washed from one pyramid into another. It is doubtful if this could be brought about even with a considerably higher velocity.

When coarse gravel was used (B and C) there was no lifting of the gravel, but only when fine gravel was used (D and E) was the gravel disturbed, in some cases being expanded by the action of the water according to the velocity.

The results of these experiments are shown in Table V.

Trial No. 5.—Trial No. 5 was made with the same arrangement of balls and marbles used in Trial No. 4. Above this was placed the following arrangement of gravel: 1.5 in. coarse gravel, ⅝ to 1 in.; 1.5 in. medium gravel, ¼ to ⅝ in.; 3 in. fine gravel, No. 13 mesh to ¼ in. Above the gravel was placed 12 in. of one of the various sands described above.

The action of the gravel and sand layers during Trial No. 5 was all that could be desired. In no case was the gravel disturbed and the sand was uniformly expanded.

Analyses of these various sands have showed how complete was the separation of the sands into sizes by the process of washing. They also indicated considerable va-

TABLE V. RESULTS OF TRIAL NO. 4 WITH TWO LAYERS OF BALLS, ONE LAYER OF MARBLES, AND VARIOUS GRAVEL LAYERS

System	Vertical velocity mm. per sec.	Vertical velocity ft. per min.	Results
A—Balls and marbles	13.7	2.5	Marbles revolved slowly
	16.0	3.2	Marbles moved (1)
	17.9	3.5	Marbles moved (2)
	25.0	4.9	Marbles moved (3)
B—Like A with 1 in. of ⅝ to 1 in. gravel.	13.4	2.6	No gravel lifted
	17.7	3.5	No gravel lifted
	21.8	4.3	No gravel lifted
	25.0	4.9	No gravel lifted
C—Like B with 1.5 in. of ⅝ to 1 in. gravel and 1.5 in. of ¼ to ⅝ in. gravel	16.6	3.3	No gravel lifted
D—Like C with 1 in. of No. 13 mesh to ¼ in. gravel.	13.1	2.6	No gravel lifted
	14.9	2.9	No gravel lifted
	17.5	3.4	Slight boiling
	21.8	4.3	Gravel expanded ¼ in.
	25.0	4.9	Gravel expanded ¼ in.
E—Like D with fine gravel layer increased to 3 in. in depth.	13.7	2.5	No gravel lifted
	16.0	3.2	No gravel lifted
	17.9	3.5	No gravel lifted
	20.3	4.0	Slight lifting of gravel more marked at periphery of filter
	21.8	4.3	
	25.4	5.0	Gravel boils gently

(1) Side marbles revolving, corner marbles lifted half way.
(2) Side and center marbles revolving, corner marbles lifted half way.
(3) Side marbles lifted half way, corner marbles lifted to top.

riation in uniformity. For example, the Concord sand to a degree dependent upon its size and the vertical velocity of the wash-water passing through it. It is believed that even a considerably thinner layer of fine gravel could be used in practice than the 3-in. layer used during the experiments, and with equally good results.

SORTING OF THE SAND PARTICLES BY WASHING—After the trials with each kind of sand had been made, samples were taken for mechanical analyses, from the surface of the sand layer and from various depths below its surface.

No. 1 varied in size between the surface and the bottom of the sand layer from 0.25 mm. to 0.84 mm. effective size, while the Ipswich sand varied only from 0.21 mm. to 0.31 mm.

The summarized analyses also showed how the effective size of the sands might be markedly altered by scraping the surface of the sand after washing. For example, by scraping 1 in. from Concord sand No. 1, after washing, the effective size could be increased from 0.25 to about 0.45 mm.

FIG. 3. PYRAMIDAL FILTER BOTTOM USED FOR THE MECHANICAL FILTER PLANT, BELFAST, ME.

EXPANSION OF SAND—Many data were obtained during these experiments which had reference to the sand and not to the filter bottom. Fig. 2, showing the relation between the upward velocity of the wash-water and the percentage expansion of the five sands as observed during

the experiments, is of interest in this connection.

To determine the degree of expansion the sand layer was measured before and after washing and the average elevation of the surface of the sand during washing was estimated as accurately as practicable.

It will be noted that the degree of expansion for any given velocity of water varies not only with the effective size of the sand but also with the shape and character of

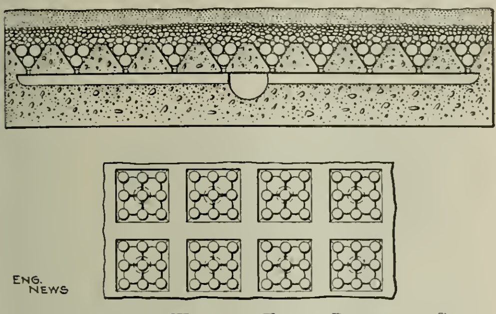

Fig. 4. Design of Wheeler Filter Bottom as Shown in Patent Application

the sand grains themselves. Consequently, two sands of different sizes and uniformity, like Nos. 1 and 3 and 2 and 5, respectively, show similar degrees of expansion with various velocities of wash-water. Still greater variations could be expected if the sand contained mica, limestone or other minerals varying in shape, specific gravity and structure.

The effective size of the sand, that is, its 10% size, is of especial value for determining the friction of the sand layer when water is being filtered through it. For estimating the friction during washing, the average size of the particles is of far greater importance. The value nearest the average size which is given by the ordinary sand analysis is the 60% size, that is, the size when 60% of the sand is finer than any given diameter.

The uniformity coefficient of the sand layer affects its hydraulic value and also the degree of expansion of the sand layer with varying velocities of wash-water (Fig. 2).

In addition to the above trials, the optimum velocity of wash-water for each of the five sands used was determined; also the percentage expansion of each sand when washed at the optimum velocity. Other experiments were also made but like the ones just mentioned they had no reference to the design of the filter bottom, although its precise action made the results of filter-sand experiments of greater value than usual.

Results in Practice

The filters at the Belfast Water Co., mentioned above, have been in operation a very short time. Nevertheless, there is no reason to believe but that they will continue to operate as efficiently in the future as they do at present. Since the Belfast filters (Fig. 3) were designed, Frank A. Barbour, of Boston, Mass., has embodied the Wheeler filter bottom in the design for the new water-purification plant for the city of Akron, Ohio, and negotiations are now in progress for its use in a still larger plant.

To protect the design (Fig. 4), patents were applied for on June 26, 1913.

The Gatun Hydro-Electric Plant, Panama Canal*

The following particulars of the hydro-electric plant at Gatun Dam are of interest on account of the part of this station in the general canal development and because of the various features themselves. The project for the use of electric energy in various services in connection with the operation of the Panama Canal has been noted from time to time in Engineering News as the plans developed (and were summarized in an article on the lock-control system, Dec. 25, 1914).

The Gatun Lake storage offers good opportunity to generate current for lighting the canal, for operating the gates and other locking machinery, for the towing locomotives, for coal-handling plants at both ends of the canal, for machine shops, water-works, dry docks, and possibly in the future for hauling trains on the Panama Railroad.

The Gatun plant has a present capacity of 6000 kw and this can be increased to 12,000 kw. if advisable, outlet pipes having been installed in the dam along with the original pipe lines. (To insure continuity of service in case of accident, a 4500-kw. steam-electric station at Miraflores, erected a few years ago to supply power for construction work, will be ready to pick up the load when necessary.)

Operating Head and Intake—The gross head available from Lake Gatun to mean-tide level of the Pacific Ocean varies from a maximum of 91 ft. in the extreme flood times to a minimum of 79 ft., to which level the lake may possibly drop toward the close of the dry season. The plant is designed consequently to develop full capacity under an effective head of 75 ft. For three or four months of every year there is absolutely no rainfall on the Isthmus; and during this period, it is desirable to conserve the water to as great an extent as possible. Maximum efficiency was therefore demanded for the apparatus of both the waterwheel and generator manufacturers. As shown in Fig. 1, in the masonry at one side of the Gatun dam spillway, are six 12-ft. passages protected with iron trash racks. Only three pipe lines have been put in with their headgates $10\frac{1}{2}$ ft. in diameter.

Each gate has two steel stems with bronze nuts in roller bearings; each pair of nuts is driven through bevel gears by a 15-hp. motor. Hand-operating mechanism is disconnected during power operation (two men are required to open).

The gates have an automatic control consisting of a limit switch geared to one of the gate stems and a float switch actuated by the water in the pipe. The gate-motor switch is closed at the power house, the gate being closed and the pipe line empty. When the gate has opened a distance which would fill the pipe line in about five minutes, the limit switch opens the circuit and stops the motor. When the pipe line is filled and the water rises in the 36-in. vent just below the gate, it actuates a float switch and again closes the motor circuit, thereby causing the gate to be opened fully, when the limit switch again operates to prevent over-travel. The gate is closed by reversing the main switch.

Pipe Lines—Each gate is bolted to a steel pipe line 10 ft. 6 in. in diameter with an average length of 420 ft.

*From information furnished by the General Electric Co., Schenectady, N. Y.

The pipes are of $\frac{5}{8}$-in. plate, courses 8 ft. long and three sheets around the circumference. Each course has a center ring of $\frac{3}{8}$x3-in. Z-bar. The pipes are covered with reinforced concrete as rust protection. They come down on a uniform slope and turn under the station with 90° bends of 30-ft. radius. Each pipe is arranged for Pitot-tube tests in service.

Each pipe has two 6-in. saddle-nozzle connections located 15° on each side of the vertical center line of pipe. From these connections there are two Pitot-tube guide supports placed across the pipe at right angles to each other. These are bolted in the pipes and, while intended to be permanent, can be removed readily if desired.

STATION BUILDING—The principal buildings are designed along simple lines in harmony with the unbroken surfaces of concrete of the adjacent engineering works. For the same reason they are devoid of all modeled ornament, the plain wall surfaces are relieved only by the base moldings, cornices and the architraves bounding the openings. This has the effect of enlarging the apparent size of the buildings, though they must appear dwarfed by proximity to large masses of concrete.

The station building is 61x137 ft. and 74 ft. high. There is a single room open to the roof, exposing the trusses upon which is laid the reinforced-concrete roof slab, which, in turn, receives the red Spanish tiles. The walls are of poured concrete, 30 in. thick to the level of the crane rails, near the cornice. The exterior overhang of the main roof is 13 ft. 2 in. and that of the monitor roof 4 ft. 8 in., the exceedingly large projections having been generally adopted for all the permanent buildings in the Canal Zone as a shelter from tropic rains, as well as from the heat of the sun.

Beyond the general use of tile for flooring, and an interior white enameled brick wainscot 14 ft. high, to relieve the coarseness of the walls, there is no difference in the finish of the concrete surfaces within and without. There are four principal interior elevations: (1) turbine pit with an area of [illegible] sq.ft., [illegible] ft. below the main floor and reached by [illegible] stairs [illegible] from the pit to store, compressor and pump rooms. The pit is lined with white enameled brick. Between pit and main floor levels are the following rooms—separate [illegible] for black and white employees; (2) the main floor, partitioned off to give two [illegible] passageway for [illegible] electrical equipment, etc., and the other as an uninterrupted passage along the line of turbines; (3) a mezzanine gallery reached by concrete stairways at the building ends; (4) a second gallery which with the mezzanine carries the switches, reactances, control boards, etc. These run the entire length of the building; in one corner are two superimposed galleries, one used as an office and the other as a machine shop.

TURBINES—The three 2000-kw. main generating units in the hydro-electric station are each driven by a special, 30-in., vertical, single-runner, Francis turbine. Each has a maximum capacity of 3000 hp. when operating under an effective head of 75 ft. and at a normal speed of 250 r.p.m. The center of the runners is 20 ft. above tail water.

Water is discharged through steel-lined ($1\frac{1}{4}$-in. plate)

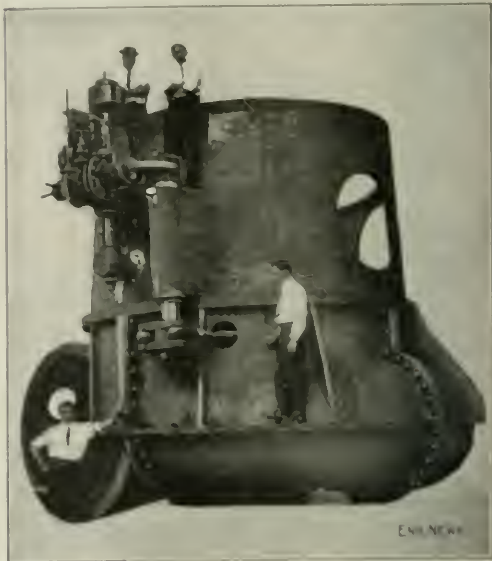

FIG. 2. SPIRAL CASING FOR FRANCIS TURBINE, DISTANCE RING AND GOVERNOR

FIG. 1. PANORAMIC VIEW OF HYDRO-ELECTRIC STATION WITH PENSTOCKS AND SPILLWAY FOR MAIN DAM; GATUN LAKE, PANAMA CANAL

concrete draft tubes, which are 71 in. in diameter at the discharge from the runners and increase to an elliptical section of 9 ft. by 17 ft. at horizontal outlets.

The spiral casings carry the generator frames through cast-iron distance rings (Fig. 2). A roller thrust-bearing on top of the generator frame carries the load of revolving parts (32 tons); at full capacity on upward thrust of 20,000 lb. relieves the bearing. Geared to the main shaft is a small oil pump for the thrust-bearing; the returning oil lubricates the lower guide.

The turbine runners (weight 7000 lb.) are of bronze, hand finished, bored taper and held on the shaft by bronze nuts. The wicket gates are steel castings, hand finished; the pivot stems rise through glands to levers. The levers are linked into the gate ring and the whole gear is outside the turbine casing except the gates proper. Oil-pressure governors are provided, geared to the main shaft. Small motors permit remote control of governor setting to vary speed for synchronizing.

Generators—The main generators are of a three-phase 25-cycle revolving-field type developing 2000 kw. at 0.8 power factor, 2200 volts and 250 r.p.m. They have 25% two-hour overload rating.

The exciter is mounted below the main generator but is readily accessible through large holes in the distance ring, a platform being provided inside the ring from which the exciter commutator and generator-collector rings may be reached. All windings were made moisture proof on account of extreme climatic conditions. Provision is made for securing the magnet frame of the exciter to the revolving element of the generator, so that the complete rotating element, together with the exciter frame, is raised at once in disassembling. In addition, there are two motor-driven exciters.

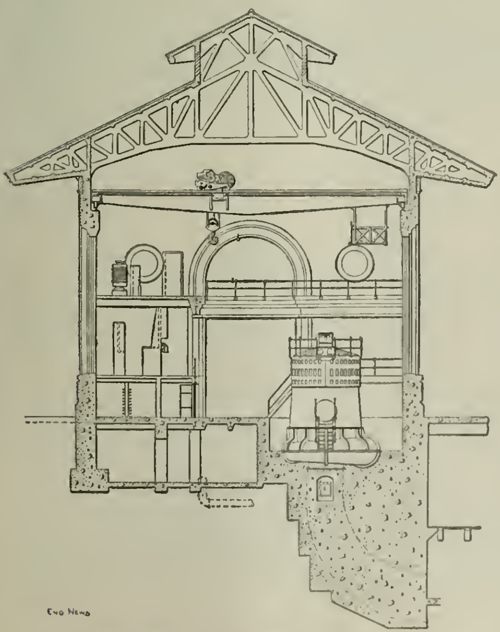

Fig. 3. Sectional Elevation of Gatun Station

The official tests showed generator efficiencies (at 0.8 power factor) of 95.1% at 2000 kw., 94.3% at 1500 kw., and 92.5% at 1000 kw.

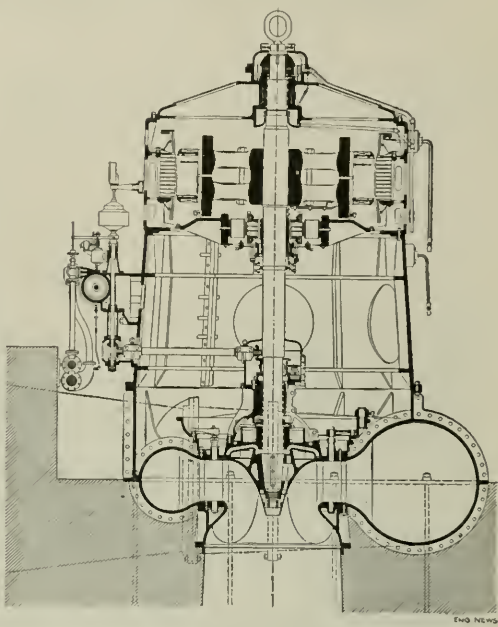

Fig. 4. Section through Turbine Generator and Exciter, Gatun Hydro-Electric Station

Switchboards—Current is transmitted at 44,000 volts, but the step-up transformers are not in the main stations. The connection schemes throughout follow a double-bus, double-switch scheme as being most flexible for uninterrupted operation during repairs. The main switchboard comprises a control bench and a vertical rear panel for relays, uniters, etc.; a second story houses the motor-operated rheostats.

The complete hydraulic equipment was designed and built by the Pelton Waterwheel Co., of San Francisco; the electrical apparatus was designed and built by the General Electric Co. All details of design and construction were subject to the requirements and approval of the engineers of the Isthmian Canal Commission.

Structural Steel Frames of very considerable size and complication of design are being used in Europe as hangars for large dirigible balloons. In "Le Genie Civil," May 23, 1914, there is an extended article describing some typical sheds in use in France and Germany. In general these sheds consist of a series of simple arch frames, similar in design to the usual armory roof in this country but of much lighter material because of the very light roofing. They are usually rectangular in plan, providing room for one airship with exit or entrance at either end, but some of the newer sheds are wide enough for two airships, side by side, and proposals have been made to build them in triangular or in starshape plan, so as to provide entrance in the direction best favored by the prevailing wind. To accomplish this latter end, at least one shed has been built, 413x85 ft. in plan, mounted on a turntable so that it may be turned to meet any wind condition.

The Design and Construction of Sanitary Sewers, Carlisle, Penn.

By C. A. Bryan*

SYNOPSIS—This article is published not because it describes anything novel but rather because it illustrates the opposition and delays encountered and the methods commonly followed establishing a sewerage system for a small town.

The borough of Carlisle, Penn., has a population of about 10,000, is of slow growth and is considered very conservative. That the majority of the younger generation realize the necessity of improvements is evident but their influence is far outweighed by the majority of their elders who are opposed to improvements of any nature.

Sewerage was agitated in Carlisle as far back as 1905, at which time Chauncey Ives, Chief Engineer for the Cumberland Valley R.R., was consulted and prepared an estimate of the cost of sewering the town. No further definite action was taken until 1907-08, when T. Chalkley Hatton, Consulting Engineer, of Wilmington, Del., was instructed to prepare plans and specifications covering the proposed work. Plans were submitted in 1908 and approved by the Borough Council and a special election authorized to determine by popular vote whether the system should be constructed. The proposition was defeated. At the expiration of two years, the time specified in the act of assembly regulating elections of this nature, a second election was held, and the sewerage system was authorized. Exceptions to the result of this election were taken, a bill in equity filed and an injunction restraining the borough from proceeding with the work was issued. The case was carried up to the Supreme Court of the State and was finally decided in favor of the borough. The work was therefore advertised in March, 1913, the contract signed and construction work started in April, continued through the summer, and the system finally finished during March, 1914.

Photographs, here reproduced as Figs. 1 to 4, were taken for the purpose of demonstrating the need for a sewerage system. These views were not taken to present the worst phase of the question, but to show that sewerage was unquestionably necessary.

Fig. 5 is a plan of the borough, showing the layout of the streets and the sewer lines. Elevations of the street surfaces and of the inverts of the sewers are given at all street intersections [but not all elevations are reproduced.—Ed.]. The town is divided into two natural drainage areas by the two principal streets, Hanover and High, as the ground falls to the east and west of Hanover St. and also to the north and south of High St.

After considerable study it was determined that the entire sewage of the town could be collected by two intercepting sewers, one to carry the sewage from the northern portion of the city and the other to carry that from the southern section, as shown by the map. For convenience in handling, the plan was then subdivided into five sections—each being entered by a main branch line which joined either one or the other of the two intercepting sewers.

From the company supplying the city with water, what information relative to the total water consumption of the city that they could furnish, was obtained. This information was at best very approximate inasmuch as the company had no accurate records. It was estimated that the average per capita consumption per day would amount to 100 gal., and the system was designed on this assumption.

The minimum velocity of flow of the sewage through the mains was fixed at 3 lin.ft. per sec., and the grades determined in accordance therewith. The topography was such that this velocity could be obtained without undue expense and in only a very few instances was it necessary to resort to the minimum velocity of flow.

It was assumed that the rate of increase in the population of Carlisle would be 500 per year (considerably greater than in the past), and it was also assumed that the system will serve 25,000 people, or more than double the present population of the borough. Allowance was made for an infiltration of ground water into the system amounting to 5000 gal. per mile of sewer per day.

The sizes of the various mains were then computed, profiles of each sewer were made, and an estimate of the cost of the lateral sewerage system computed.

In designing this system, careful attention was given to both the matter of cleaning out the mains and to their ventilation. The former was accomplished by placing the manholes at a distance of not over 250 ft. apart and the latter by providing eight holes, each 6x1 in. in size, in the center of the cast-iron manhole covers. To prevent dirt and other foreign matters from getting into the sewers through these holes galvanized-iron catch buckets were hung in each manhole frame just under the cover. At the dead ends of all sewers, flush tanks were placed and at each flush tank a lamp-hole was built, thus providing a method whereby the sewer barrel between the flush-tank and the next manhole downstream could be easily inspected. Each flush-tank was designed to discharge a flush of 190 gal. into the sewers. Miller siphons 5 in. in diameter were specified and it was decided that the tanks would operate twice in 24 hours when put into service.

The specifications also provided that previous to the final acceptance of the system by the engineer each section of sewer should be tested by the passage through it of a ball whose diameter was to be 2 in. less than that of the sewer itself. The testing of the entire system of lateral sewers was put under the supervision of one of the inspectors well qualified for the work and a resident of the city. The city is thereby assured that the sewers when taken over were practically clean.

In computing the cost of construction, it was quite necessary to obtain an approximate estimate of the amount of rock to be removed. This was accomplished by taking a boring at each street intersection and also at a point in the middle of each block. These elevations were then plotted upon the profiles and the quantity of rock estimated.

*Resident Engineer, Sewerage Commission, Carlisle, Penn.

It was estimated that the lateral system would cost $49,600 to construct.

Bids on this work were asked for in March, 1913, and the lowest bid for the construction of this portion of the system was submitted by the H. C. Brooks Co., Inc., of Martinsburg, W. Va., and the work was awarded to it. Construction work was started early in April and continued through the summer and up to February, 1914, when bad weather set in just after the last block of sewer had been laid. During construction nothing especially difficult was encountered, the contractor finding but little ground water to contend with, and fully 80% of the work was laid in dry trench. More rock was encountered than was estimated and as it was all limestone and very hard to remove, progress was slow. In most of the alleys in which sewers were built, progress was also slow because of the extreme narrowness of these alleys, a fact which made it difficult to take care of the materials excavated from the trench. This was especially true in those alleys in which the cut was deep.

In general, the earth excavated was of a clayey composition and the sides of the trenches did not require much shoring. In those ditches in clay, where the cut exceeded a depth of 9 ft., considerable difficulty was experienced. In one stretch where the ground appeared to be of a character similar to that encountered in the other portions of the town, it proved very treacherous and caused no end of trouble. The material seemed to pulverize upon exposure to the atmosphere and was constantly falling upon the workmen in a sort of fine shower, and it

Views Taken for Use in Campaign to Show the Need for Sewers in Carlisle, Penn.

(Fig. 1. Cesspool back of laundry. Fig. 2. Laundry wastes from overflowing cesspool. Fig. 3. A Main St. eyesore, but common to whole town. Fig. 4. Alley in east end of borough.)

was soon shown that the only way to prevent this was to sheet the ditch throughout.

The futility of attempting to execute work of this sort by using local labor was well illustrated at Carlisle. The contractor experimented with local labor for fully two months and was able to complete only about 1.5 miles of sewer in this time. Local labor was therefore discarded and foreign labor imported and retained on the work until it was completed.

The final estimate given the contractor shows that a total of 7.2 miles of 8- to 18-in. vitrified-pipe sewers have been constructed at a cost of $71,000, or $9,750 per mile of completed sewer. The increase of approximately $20,000 in excess of the estimated cost is due principally to the fact that the rock encountered exceeded by nearly 50% the quantity estimated. This unexpected increase in the rock excavation cannot be laid to the engineer, for his preliminary investigation was carried on much more carefully than was warranted by the amount paid him by the town for his services.

Fig. 3. Layout of Sewerage System of Carlisle, Penn.

(Only a few samples of the figures showing grade elevations are here reproduced.)

The cost of constructing this system of sewers will be borne by an assessment levied upon abutting property owners on the basis of $1.20 per front foot. In the case of corner lots where sewers have been constructed on two sides, the assessment on the street on which the property fronts will be the same as in any other case, while

for the computation of the assessment on the other frontage, distances up to 130 ft. will be divided by two and the quotient assessed on front footage at the rate adopted. In cases where the distance on the side exceeds 130 ft., 65 ft. will be deducted from the total side distance and the remainder assessed as front footage. A survey of the town showed that a total of 60,000 lin.ft. was assessable. The rate quoted above was determined on this basis.

This sewer system was designed by and installed under the supervision of T. Chalkley Hatton, now Chief Engineer of the Milwaukee Sewerage Commission, Milwaukee, Wis. The writer was the resident engineer in charge of the work.

In conclusion, the writer is of the opinion that the attitude of the citizens of Carlisle in regard to the construction of the sewer system is illustrative of a condition unfortunately only too prevalent throughout the country. Sewerage in any city of the size of Carlisle is a necessity beyond a reasonable doubt. The demands for it on the grounds of the public health are constantly growing stronger and stronger. Had the citizens of the borough of Carlisle realized the necessity of sewerage at the time when the proposition was first submitted to them every taxpayer would be unquestionably better off. The increase in the prices demanded for labor, materials and other commodities used in the construction of this system was so great during the years that this proposition lay dormant that it has increased the cost of the construction of the system by many thousands of dollars. In addition, the borough has been obliged to bear the expenses of a long drawn out lawsuit which failed to accomplish its purpose.

The experience of Carlisle should serve as a lesson for and be carefully studied by the authorities of those cities in which this matter is now being agitated.

Water-Works Plans of the Public-Utilities Commission of Denver

By A. Lincoln Fellows*

In the year 1910, the people of the city of Denver created a commission called the Public Utilities Commission, whose only powers, however, were to have charge and control of the operation of a water-works, to supply the city and county of Denver and its inhabitants with water for all uses and purposes, and to have control of such other public utilities as might be acquired by the city.†

†See "Eng. News," June 2, 1910, p. 659.

This Commission was specifically directed to offer to The Denver Union Water Co. the sum of $7,000,000 for its plant, and if this were not accepted, to proceed with the construction of a new plant. Naturally, as the valuation of the plant of the Denver Union Water Co., made about a year prior to that time, gave a value of $14,400,000 to the plant, the company refused to accept the offer and brought suit restraining the city from proceeding with the construction of a new plant. This case was finally settled by the United States Supreme Court, which rendered an opinion to the effect that the city had acted entirely within its rights, and that the Public Utilities Commission might proceed with the construction of a new plant, if it desired to do so, in accordance with the terms of the charter amendment, previously mentioned. This decision was handed down in July, 1913, and immediately thereafter the Commission appointed a committee of engineers to make an investigation as to the value of the plant of The Denver Union Water Co., and also make a preliminary estimate as to the cost of a new plant. This committee consisted of the engineering member of the Commission, A. Lincoln Fellows, and of Edmond C. VanDiest, of Colorado Springs, and Charles P. Allen, formerly Chief Engineer of The Denver Union Water Co.

The sum allotted and the time permitted for making the investigations were so limited, that surveys of a new plant were impossible, and only an incomplete report could be made. The committee reported in January, 1914, $10,045,000 as the physical value of the plant, including approximately $375,000 as development expenses. The committee did not place any value upon water rights claimed by the company, taking the position that this was a legal question, which could be determined only by the courts, and no allowance was made for going value other than the development expenses, this being considered also a question to be passed upon by the courts.

The Commission also gave a preliminary estimate of the cost of $12,750,000 for a new plant for the city, this estimate, however, as was stated in the report, being made without surveys, and with only the most incomplete information.

Soon after the completion of that report, at another election held in the city, a plan proposed by some of the business men of the city, which provided for arbitration as to the value of the Denver Union Water Co.'s plant, was rejected by the people by a very large majority. Immediately thereafter the Public Utilities Commission commenced further investigations for the acquisition of certain reservoir sites, and the preparation of plans for a new plant, this being the only course open to the Commission. It has, however, been hampered by another suit, seeking to enjoin the Commission from issuing bonds. The bill was, however, dismissed in the Federal District Court on June 10, 1914, and although an appeal was taken to the Court of Appeals, the Commission is proceeding to advertise the sale of the $8,000,000 of bonds which have been authorized by the people: bids to be opened July 20, 1914. The bonds are to be issued in blocks of $500,000 each, as money may be required.

The Commission plans the commencement of surveys and the preparation of plans as soon as money is available for its work. Certain tentative plans have already been drawn, which will be submitted to a consulting board to be selected at the proper time by the Commission, and the details will then be passed upon by the consulting board.

A number of plans have been presented to the Commission, as follows:

(1) The use of the water of the South Platte River, which is now used as the source of the water-supply for Denver by the Denver Union Water Co.

(2) Tunneling of the Continental Divide by means of a tunnel, approximately 4½ miles in length, and the diversion of the waters of Blue River from the Western to the Eastern Slope. The waters would then be turned

*President, the Public Utilities Commission of Denver; General Manager, the Field, Fellows & Hinderlider Engineering Co., Denver, Colo.

down the South Platte channel to be again taken out in accordance with the laws of the State of Colorado and used for supplying Denver with water.

(3) A similar plan might be adopted with reference to the waters of the Fraser River. An additional complication in this plan is the fact of the voting of $3,000,000 by the city of Denver for the construction of the so called Moffat Tunnel, which tunnel, while it is to be used for railroad purposes, is nevertheless, in theory at least, primarily for the purpose of bringing water from the western to the eastern slope for the use of the city of Denver.

(4) A similar plan with reference to the waters of Williams Fork, or a combination of Williams Fork and Fraser River.

Whatever course is adopted, large reservoirs must be constructed for the regulation of the supply to be used in the city. Fortunately, good reservoir sites are available and can be had for the purpose when required.

It is the Commission's intention to proceed as rapidly as possible with the preparations of the plans for the construction of a new plant, but as yet no details are ready to be given out. It is hoped that by the first of August parties can be sent into the field for the commencement of this work.

It will be of interest also to note in this connection that the City Council recently passed an ordinance, initiated by the people of the city, for the purpose of reducing the rates of the Denver Union Water Co. 20%. The company has brought suit to restrain the City Council from carrying out the provisions of the ordinance on the usual theory that it is confiscatory. A master has been appointed by Judge R. E. Lewis for the purpose of hearing the testimony, and the hearings are now going on. The company has engaged as its experts in the case Clarence Goldsmith, John R. Freeman, W. L. Holman, George G. Anderson, and Leonard Metcalf. The city will depend for its case largely upon cross-examination and the testimony of local men familiar with various details. The main questions at issue are:

(1) The value of the physical plant.

(2) The value of the water-rights claimed by the company.

(3) Going value.

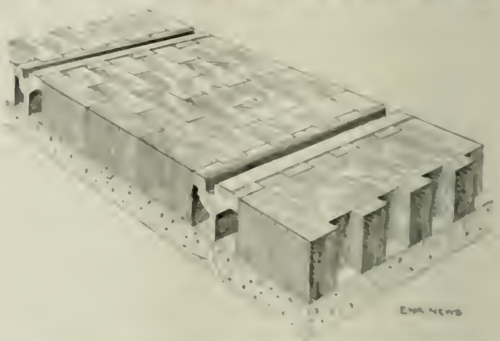
The company claims approximately $11,500,000 for the physical value; $3,[illegible] for value of water-rights, and $1,[illegible] for going value, a total of $17,000,000.

The city on the other hand contends that there should be included in the physical valuation only those parts of the plant actually useful at the present time in furnishing water to the city; that only such amounts should be paid for water as will compensate the company for the water-rights which it has purchased, and that these amounts should be included in the values given for the basis with water-rights; and that in a case, such as this, where there is no franchise and no expectation of granting a franchise, but where, on the other hand, the company is allowed to use the streets only by sufferance and until such time as a new plant shall be completed, no going value should be allowed.

In answer to this last contention the company contends that the fact that the construction of a new plant is threatened should entitle it to increased rates because of the ultimate abandonment of the plant to a condition of complete uselessness within a period variously estimated at from five to seven years. At the present writing the master has not definitely ruled regarding this point, but is admitting evidence upon practically all relevant points for later consideration.

A Street-Railway Rail for Block-Paved Streets

The accompanying view shows an indented rail which has been in service for eight years on one of the street railways of Paris, France. The rail was designed to provide a bond between the paving block and the street-car



A Special Rail to Prevent Excessive Wear between Track and Pavement

(From Le Génie Civil, Paris, France.)

rails so that the usual excess wear of the blocks immediately adjacent to the rail might be avoided.

The rail is of the usual tramway type, but is rolled with alternate notches into which the adjacent paving blocks fit. This bond acts to bridge the wearing action of wheels alongside of the rail and the device has been quite successful in retaining an even surface at the edge of the rail. The City Council is so satisfied with its performance in the one place where it has been laid that a much longer stretch is to be placed with a view to further experimentation.

The Fottinger Hydraulic Turbine Transmission for marine propulsion is being developed on a considerable scale in Germany. In the Fottinger system, high-speed steam turbines are directly connected to hydraulic turbines. The water delivered from the latter exerts its power to rotate a low-speed hydraulic turbine mounted on the propeller shaft. While there is in this system a continuous loss due to the friction of the water passing through the two hydraulic turbines, this is claimed to be more than offset by the ability to use a steam turbine of very high rotative speed and consequent compactness and efficiency and a propeller at the stern of the vessel of low rotative speed and corresponding high efficiency.

One of the vessels on which the system has been applied is the [illegible], a German [illegible] steamer of [illegible] tons. The vessel is equipped with a steam turbine developing [illegible] h.p. at [illegible] r.p.m. The low-speed hydraulic turbines which drive the propeller shaft run at [illegible] r.p.m. A second hydraulic turbine on the propeller shaft has its vanes reversed so that when the water is turned into it the propeller is rotated in the reverse direction. A simple valve controls the movement of the pressure water delivered from high-speed hydraulic turbine either to the ahead or astern low-speed turbine. The system therefore has the additional advantage of avoiding the use of reversing steam turbines which are a necessity on the ordinary steam-turbine driven vessel. It is stated that the system is to be applied to a transatlantic steamship and also to a German cruiser of [illegible] tons.

Editorials

The Salem Conflagration

The horse has been stolen from the stable at Salem and it does no good now to say that the stable door should have been and might have been locked. Salem's fire department and water-supply were both insufficient; on the other hand it is doubtful whether twice the fire-fighting equipment and a liberal water-supply would have availed to stop the progress of the flames, once well started. The fire hazard of Salem lay in the extensive frame construction in and surrounding high-value districts, and the narrow streets.

The local fire department was augmented by about 60 pieces of fire apparatus and 700 firemen from neighboring cities and towns; but this was too much of a tax on the water-supply, which was further reduced by leakage from broken supply pipes which could not be shut off. A number of buildings were dynamited, in the path of the original fire, but the wind carried burning embers over the waste and the flames advanced without check.

Warnings to Salem were not lacking. As far back as 1907, the National Board of Fire Underwriters made a report on fire risks in Salem. The following significant extracts are taken from the general summary of that report:

Water-Supply and Fire Department—Water supply from sources barely sufficient for present needs. Fire department weak in both apparatus and men.

Building Department—Laws old and poorly arranged. No mention of many fire-protective requirements and devices.

Explosives and Inflammables—Laws inadequate. Inspection not in hands of fire department.

Conflagration Hazard—Severe in and around the principal mercantile districts and the south mercantile and manufacturing district.

Salem has received a fearful blow, but with the energy and pluck characteristic of American cities which have been visited by a similar calamity, is already planning to rise from its ashes. With the erection of new buildings of more modern design and of materials more fire-resistive in the burned-over district the fire hazard of Salem will be less portentous.

Other cities where similar conflagration risks exist might well learn from Salem's disaster. Frame structures cannot, of course, be replaced in a day by steel and concrete and brick; but an inadequate water-supply and weak fire department ought not to be allowed to continue in any city, where such serious conflagration hazards exist.

Engineering Societies and the Public

There are two opposing views as to the functions of an engineering society. One view is that such a society should concern itself solely with the purposes for which such societies were originally organized, which may be defined as the social and professional advantage of its members. The other view holds that engineering societies should improve the opportunities for public leadership which are opening before them at the present time and should become working organizations rather than social clubs.

An excellent illustration of the sort of responsibility which is being laid upon engineering societies where they are willing to assume it is afforded by the laws regarding steam boilers. A half-dozen States have enacted laws fixing standard requirements which makers and users of boilers must observe, and also in some cases establishing examinations for those responsible for the care of steam boilers and their inspection. These legal requirements fixed by different States are so varying and in some instances conflicting that they are a serious burden to steam-boiler manufacturers and purchasers.

It is all very well to say, as many engineers do say, that the States should not pass legislation of this sort interfering with private industry and matters of a technical character. The fact to be faced is that such legislation had been enacted and much more of it is certain to come in the near future. It is said on good authority that the legislatures of some seven or eight states are practically certain to pass a steam-boiler law at the next session.

The American Society of Mechanical Engineers, fortunately, has had a committee at work on this matter for some time and it has already framed a preliminary report and will very likely have a complete report ready for the December meeting of the Society. That report is, we understand, likely to be accepted by the various legislatures as a guide in the framing of laws. Not only this, but other organizations and interests directly affected by such legislation are looking to the Mechanical Engineers to take the lead.

The reason for this is obvious. The public is deeply distrustful of business organizations. If the associated steam-boiler manufacturers should frame a law and offer it for passage by the States, charges would at once be circulated that they had so framed the law as best to protect their interests. The same sort of criticism might be brought against the steel makers, or the boiler-insurance interests. A professional society like the Mechanical Engineers, however, can come before the public and stand a much better chance of having its work accepted as authoritative and unprejudiced.

It may be said that the States should employ and pay engineers as expert advisers to do the technical work of drafting such laws; but suppose the several States did follow this course. What are the chances that the engineers whom a legislative committee might select for work of this sort would be such men as the profession would approve as well qualified to carry it out? Would not the inevitable result be the passage of different laws by different states embodying different and conflicting requirements, making ten times worse the confusion which already exists?

This is but an example of numerous cases where the public demand for legislation effecting Government control of industry can only be satisfied if the expert technical knowledge of the engineer is sought. And it is

vastly easier to shape legislation in the making—to aid in making a law effective and preventing it from being so framed as to work serious injustice—than it is to secure the repeal or amendment of a bad law after it has been placed on the statute book.

It deserves emphasis, too, that the engineering organization is as powerful in this matter, provided it will realize and use its influence, as the individual engineer is helpless. Organization in every branch of trade and industry and professional work are making their influence felt in these matters. The engineer must realize that his own organizations, formed originally for the purpose of mutual benefit and the advancement of the profession, must assume the responsibilities that properly belong to them in working out solutions for the serious social and industrial problems of the present day.

The Neglect of Brick Pavements

In the notable appeal for the substitution of brick pavements in place of bituminous macadam in State highway construction in New York, made by Gov. Glynn some months ago, our readers will remember that he based his chief argument on the small cost of maintenance of brick pavements, placing this maintenance cost at no more than $50 a mile per annum.

From recent inspection of a considerable mileage of brick-paved roads and streets in various parts of the Central West it appears to us that a very considerable percentage of the brick pavements recently laid are suffering deterioration because they apparently have had nothing at all expended on them for maintenance. On many miles of brick-paved roadways in Cuyahoga County, Ohio, which have been laid within a comparatively short time, and are good examples of first-class construction, the only defect noticeable is longitudinal cracks, extending usually along or near the center of the roadway. So long as these cracks remain merely open cracks, they do no injury to the road and apparently nobody pays any attention to them.

What happens, in no very long time, however, is that the calks of horseshoes and steel tires gradually chip away the sides of the crack, and what has been a crack becomes a groove. As soon as the groove becomes wide enough for a steel tire or a horseshoe calk to drop into it, the destructive effect is rapidly accelerated. One sees not a few places on these brick roads where depressions half an inch or more in depth, and six inches to a foot in width, have been hollowed out along the line of what were originally mere cracks in the pavement.

This is, in fact, exactly what would naturally be expected to happen, and what is bound to happen so long as the fallacy obtains that a brick pavement once well laid needs no repairs whatever. It is entirely true, we believe, that such a pavement needs a comparatively small amount expended on it to keep it in good repair, provided it has been originally constructed in a first-class manner, but that small amount it must have, even though it be as little as $50 per mile per year, or damage will be done compared with which the cost of repair would be a mere trifle.

It would be an exceedingly easy matter when these longitudinal cracks form in a brick pavement, to fill them flush with the surface, either with a cement grout of the consistency of cream or with a mixture of tar and sand in the same way that cracks in concrete roads are mended. From the practical point of view, the tar and sand is probably the best possible material to use. About the only objection that we know of is that it is more or less unsightly and brings the defect to notice just as it does when the same method of repair is applied to a concrete pavement. If cracks in concrete pavements could be filled with cement grout, so that the cracks would not be noticeable, instead of filling them with tar, which advertises the crack to everybody who passes over the road, the reputation of the concrete road would probably be a good deal higher, even, than it is.

City Governments and Electric Lighting Companies

Relations between cities and electric-lighting companies are to be considered at a national conference of city officials next autumn, a call for which has just been issued by Mayor Blankenburg, of Philadelphia, in cooperation with Mayor Mitchel, of New York, Mayor Harrison, of Chicago, Mayor Baker, of Cleveland, and Mayor Shroyer, of Dayton, Ohio.

In the call for this conference, which was sent out last week, it is stated that the city of Philadelphia is soon to appeal to the new Public Service Commission of Pennsylvania, for the adoption of a proper schedule of rates for the sale of electric light and power in Philadelphia. In preparing this case for presentation to the Commission, it has been found that in previous rate cases before Public Service Commissions of other States the side of the public has seldom been adequately represented, while the organization of public-utility companies has in its service the best informed and most able men to be found.

Mayor Blankenburg's letter continues as follows:

> If the cities do not join together for the presentation of their cases, as the public utility companies have done, the laws and precedents established by the Commissions stand in danger of being biased by the able arguments of the representatives of the corporations.
>
> The equipment required for an adequate presentation of the rights and interests of the people involves a degree and extent of technical knowledge and information which it is not practicable for any one city to obtain. It must be borne in mind that the utility companies constitute an offensive and defensive alliance probably stronger than any other interest in this country. Its weakest member is never without information and assistance of every kind. To meet this situation it has been suggested that there should be formed a bureau of public utility research, which shall equip itself to give to the cities the same able assistance which the public-utility companies' association gives to the public utility companies.

That there is need and opportunity for such an organization as Mayor Blankenburg suggests, would hardly be denied even by the officers of the public-service companies themselves, if they are candid.

So far as water-supply is concerned, there is fortunately no need for such an organization, as the proportion of water-works owned by municipalities is so large that a city desiring to present its side in a rate proceeding or a proceeding to acquire a privately owned works has no difficulty in securing able engineering and legal experts to present its side of the case.

An entirely different situation exists, however, with respect to electric lighting, gas supply and street railways. In this country, practically all the engineers in the gas business are in the employ of private companies and would run serious danger of blacklisting were they to en-

gage as experts on the public side in proceedings to lower gas rates or further municipal ownership of gas plants.

Almost the same situation exists in the distribution of electric current and it is a situation which from the nature of the case cannot permanently continue. It is everywhere recognized by candid and intelligent men, even among the officers of public-utility companies, that the growing public sentiment in favor of municipal ownership can only be counteracted by making public regulation of the utility companies a success. But public regulation can only be a success provided it is guided with the same high-class expert knowledge that is at the disposal of the utility companies themselves.

It is doubtful whether the officers of public-utility companies fully realize the extent to which they have failed to secure the backing of intelligent public opinion in the conduct of their business. We have passed through the stage of competition in the distribution of gas and electricity and the public accepts the fact that the business must be a monopoly; but being a monopoly, the principle of public control must be recognized to the fullest extent. There must be corresponding publicity in relation to corporate affairs. Sooner or later the companies must make public their actual cost sheets of generating and distributing electric current and manufacturing and distributing gas. The public is willing to pay the cost of what it purchases and a fair rate upon invested capital, but it is not willing to be unfairly taxed by reason of monopolistic control or to pay interest on dead capital.

A Searching Criticism of the River and Harbor Appropriation Bill

Senator Burton, of Ohio, is probably the best informed man in Congress on the government's work for the improvement of rivers and harbors. He served for many years while in the House as chairman of the Rivers and Harbors Committee. He was also chairman of the National Waterways Commission of 1909-10, which reviewed the whole subject of government expenditure for the improvement of navigation and laid down the policy which the government should follow to meet economic conditions of the present day.

Notwithstanding the publicity which was given to the report of that Commission and the general discussion which has taken place on the subject, river and harbor bills continue to be framed in the same old way. It is therefore refreshing to find a man of Senator Burton's ability and experience coming forward with a public criticism of the present pending river and harbor bill, which deserves to attract public attention.* Certainly it should receive the attention of engineers, for the subjects therein discussed are subjects on which the expert technical knowledge of the engineer is essential to sound reasoning.

And at the outset it may be well to lay down what is the point of view from which river and harbor appropriations should be considered. As a matter of fact, the strong influences at work for river and harbor appropriations are first of all the local interest which judges the efficiency of a Congressman by the extent to which he can draw upon the Federal treasury for funds to be spent within his district. Second comes the interest of those who wish appropriations made for rivers and harbors, ostensibly to improve navigation, but really for the benefit of lands subject to overflow, erosion, etc. In the third place come the interests which seek large river and harbor appropriation bills because of the opportunities for profitable contracts that may result. Finally comes the comparatively small minority which seeks Federal appropriations for the benefit of water transportation.

There can be no dissent, however, from the proposition that the last consideration is the only one that can in any way justify the use of the nation's funds, collected from the taxpayers, upon waterways for interstate commerce. Not a few of the Congressmen who join in the scramble to secure their proper share of the distribution from the river and harbor pork barrel frankly deplore the necessity which compels them to join in a riotous waste of the public funds for which no corresponding benefit is received.

The river and harbor appropriation bill, as reported by the House, carried total appropriations of $43,400,000, which have been increased by the Senate to $53,680,000. Of this amount about $10,350,000 is for beginning work on projects which are to be completed under the "continuing contract" system. This means that small sums have been appropriated to start works on projects for which much larger amounts must be appropriated in following years, or the entire work will be a total loss.

In the present year the amount necessary to be appropriated in the sundry civil appropriation bill on continuing contracts will be between seven and eight million dollars. On this basis, therefore, the entire amount to be spent by the government on river and harbor improvements during the fiscal year under the pending appropriation bill as reported in the Senate will be in round numbers $60,000,000.

Senator Burton, however, rightly says that it is not the amount of the appropriation, large though it is, but the methods by which the appropriations are made that most deserves public criticism. He declares that many of the appropriations are made for waterways which under present conditions cannot be profitably improved. And, further, that the bill contains large appropriations for local benefits which have little to do with navigation.

As our readers know, the idea has been spread abroad by energetic workers for river and harbor appropriations that the United States has neglected its water courses, and that this is the reason why the traffic upon them has declined and in many cases entirely disappeared. On this subject, certainly, Senator Burton, by reason of his long service on the Rivers and Harbors Committee of Congress, can speak with high authority. We quote from his report as follows:

> An erroneous impression prevails that the government of the United States has not been liberal in its appropriations for the improvement of rivers and inland waterways. This is altogether incorrect. More money has been expended for these purposes by this country than by any other of equal population or equal area.

As is well known, commerce on the Mississippi River has dwindled away until its commercial importance is today trifling. In 1880, the volume of traffic on the Mississippi River between St. Louis and Cairo was reported as 1,030,000 tons, and with a ruling depth of water of only 3½ to 4 ft. Since that time the government has

*Senator Burton has submitted a minority report on the River and Harbor appropriation bill, printed as Senate Doc. 522, 63d Congress, second session, Report 599, Part 2.

expended $15,574,000 to provide an 8-ft. depth of water over this section of the river, and such a channel has been available to traffic for years. The traffic on the river, however, has steadily decreased and was only 265,000 tons in 1912.

The money which Congress has appropriated to improve these [illegible] miles of the Mississippi River in the last 25 yr. has far exceeded the amount spent by Germany in the improvement of the River Rhine from the frontier of Holland to Strassburg, a distance of 355 miles. Yet this section of the Mississippi had only 265,000 tons of traffic in 1912, while the commerce on the Rhine was nearly 40,000,000 tons, or about 150 times as great. In addition to the amount above noted, there has been spent by the government on the lower Mississippi between Cairo and the head of the Passes since 1879 the sum of $78,-[illegible], notwithstanding which fact the traffic shows a steady decrease. It fell off one-half in the decade from 1901 to 1910.

It may be remarked in this connection that it is not always safe to take mere tonnage figures as a basis on which to estimate the importance of commerce on an inland stream. An analysis of the commercial statistics shows that in many cases the tonnage of traffic which is reported consists largely of sand, gravel and stone. In 191[illegible], more than a third of the Mississippi River commerce between Vicksburg and New Orleans consisted of these low-grade materials.

It should not be understood that Senator Burton in his report stands opposed to all appropriations for river and harbor improvement. On the contrary, he approves of the expenditure of public money upon those projects which can be shown to justify the expenditure upon them by the traffic which they bear. Many so called rivers included in the river and harbor appropriation bill are really arms of the sea. The money expended upon them to enable ocean vessels, larger or smaller in size, to navigate them and use them as harbors shows often very large returns in the way of benefits to commerce.

There is a general popular impression that the United States has been derelict in the improvement of its seaports. Regarding this, Senator Burton says:

> The United States has first-class harbors not only in much greater number than any other country of the world, but the distance between them is generally not so great as in the very densely populated countries of Europe. The Republic of France has but four of the first-class harbors, and Germany has but three. The harbors of the United States already improved, or on which improvements are well underway, surpass those of any other country.

It is with respect to the improvement of inland waterways that Senator Burton's chief criticism is directed. Prior to the advent of the railway as a freight carrier, the navigable rivers of the country rendered an important service in carrying long-distance traffic. Analysis of the present water-borne traffic proves that long-distance inland transportation by water has almost wholly disappeared. Where the rivers are still being used for freight it is almost wholly local.

Turning now to the record of actual results from the Government expenditures on inland waterways, Senator Burton instances the Red River below Fulton, Ark. For a distance of 175 miles on this river there was in 1912 a total traffic of 44,567 tons, of which 42,6[illegible] tons were saw logs. The United States has spent on the improvement of this stream $1,7[illegible], and the pending River and Harbor bill proposes to add $[illegible] to this sum. Senator Burton computes that, figuring interest at 4%, the cost to the Government for every ton of traffic carried on this stream last year would be $4.68. With the saw logs excluded (since they have been floated on the river without any improvement) the cost per ton, to the Government would be $90.56, and the cost per ton-mile, $1.53. The Red River, moreover, is not an isolated example of the waste of river and harbor appropriations by any means. The United States has spent on the Arkansas River $3,108,000, and the pending bill proposes to add $164,-000 more, yet the river carries a total traffic of only 71,516 tons in a year, of which 56,000 tons were saw logs. Going to the far West, on the Columbia River about Portland, the United States has spent about $9,000,000, and the total traffic on this stretch of the river is now only about 80,000 tons per annum.

There has been great agitation, in recent years, as many of our readers will recall, to secure the improvement of the Missouri River. Great things were promised by certain commercial associations as to a revival of boat traffic upon that stream, and the agitators were successful some years ago in inducing Congress to resume appropriations for its improvement.

Before the advent of the railway the Missouri was, indeed, an important avenue of traffic for the pioneers, but steamboat traffic on it disappeared years ago and in 1902 Congress decided that it was not worth while to expend further money on the stream. At that time the appropriations for it had amounted to $7,227,000. As a result of the agitation above referred to, the Government is now committed to a project to spend $20,000,000 more on the river between Kansas City and its mouth, of which $4,100,000 have already been appropriated. The traffic on the river in 1912 was 185,110 tons, of which sand and gravel hauled one mile made up 155,420 tons, leaving 29,690 tons for all other freight. The bulk of even this, however, was local traffic and the only long-distance traffic to be found in the record is 4174 tons of miscellaneous freight carried 330 mi., and 1404 tons of manufactured iron and steel products, carried 158 mi.

Senator Burton, however, suggests the real reason behind the agitation for the Missouri River improvement. From an official report filed in 1908 it appears that lands adjacent to the river, amounting to over half a million acres, would be benefited by the proposed improvement. Naturally the owners of this land desired to have it protected from erosion or overflow at the expense of the Federal Government.

The most signal instance of waste of public funds in river and harbor appropriations, however, is in connection with the improvement of rivers by slack water navigation. "It may be confidently asserted," says Senator Burton, "that the only waterways in the United States which can be profitably improved by the construction of locks and dams are the Monongahela, the Kanawha and the Ohio, which are improved by the Federal Government, and the Barge Canal connecting Lake Erie and the Hudson River, improved by the State of New York. It is possible also that the improvement of the Allegheny and the Black Warrior River in Alabama will prove desirable."

We should say that it is an open question whether the traffic on even these streams will in the end justify the expenditure which has been made upon their improve-

ment. Certainly at the present time, with the sole exception of the Monongahela, there has been no evidence of such a result.

As examples of waste of public funds in slack-water navigation, Senator Burton cites among others the famous Hennepin Canal, which connects the Illinois and Mississippi Rivers. Its advocates thirty years ago maintained that its construction would save the public $20,000,000 per annum in freight. Its construction dragged along over many years with the piecemeal appropriations which Senator Burton roundly condemns, and it was finally opened for traffic in 1908. Up to date the Government expenditures upon it have been in round numbers $8,740,000, and it carried last year only 11,962 tons of commercial freight. In the year 1909 the tonnage of material hauled for repairs and improvement of the canal itself was more than 22 times as great as the commercial freight handled over the canal.

Muscle Shoals Canal, on the Tennessee River, has cost the Government four and one-half million dollars and in 1912 the freight passing through the canal amounted to 5520 tons.

On the Big Sandy River, located on the boundary between Kentucky and West Virginia, the Government has expended about $2,000,000 in constructing locks and dams, and the total tonnage carried in 1912 was 500 tons. During this same period the railway operating in the Big Sandy valley handled 2,225,000 tons of freight.

These are extreme, but not isolated, examples of the practically total failure of the Government's expenditures in slack-water navigation projects to produce any benefit to commerce at all proportionate to the cost. Yet in the face of these well known facts, government appropriations for building locks and dams still continue. There might be the shadow of an excuse for them where such structures are built to complete a project already begun; but what possible excuse can there be for the Government to undertake new projects for improving inland rivers by a system of transportation which has been proved obsolete? The present river and harbor bill, however, contains appropriations to begin the construction of a complete system of locks and dams on the Brazos and Trinity rivers in Texas. Senator Burton sets the cost of the entire project at $10,000,000 for each of these rivers, and there is reason to believe that much larger sums would be required before the useless work could be carried to final completion.

Much more could be said to prove that of the sixty million dollars a year which the Government spends for navigation improvement, a large part is spent on works which afford no corresponding benefit to commerce; but the facts are already well known to many engineers. That the remedy for this wholesale waste does not lie in change of political parties is seen by the fact that the Democratic majority responsible for the present River and Harbor bill has pursued the same methods and gone merely a little farther than its Republican predecessors. It is seen also in the fact that some of the Progressive party leaders have been leaders also in the popular agitation in favor of waterway improvements.

How strongly the beneficiaries of the present River and Harbor system are intrenched is proved by the fact that with all the exposures of its iniquities by such men as Senator Burton and President Taft, and many years ago by President Cleveland, to say nothing of many others of prominence, the system still continues to draw money from the national treasury in a flood which increases year by year.

Sometime, perhaps some influential commercial or technical organization may be able to bring about a reform. Until that happens the nation will continue to calmly pour out millions a year into pools and ditches to perpetuate obsolete systems of transportation and benefit a traffic which has disappeared.

Letters to the Editor

Band vs. Spiral Hooping for Concrete Piles

Sir—Referring to the note on "Strength of Band and Spiral Hooping," in reinforced-concrete piles, in your issue of May 28, 1914, p. 1202, it seems possible that a more comparative test of the spiral and band reinforcing would have resulted from two test piles being driven under identical conditions, one reinforced spirally and the other reinforced with bands.

The effect of the band reinforcement probably was such that the two systems, being in conjunction, influenced detrimentally the weaker system. Although a great many experiments have been made to determine, if possible, the best method of pile and column reinforcement, no agreement has apparently been arrived at between the various authorities.

From his experience with reinforced-concrete piles the writer is inclined to think that the weakness of the spiral system lies in the fact that a rupture at any point must necessarily affect detrimentally the spiral binding for a considerable distance on either side of the break—this effect diminishing as the ratio of the distance from point of rupture. The whole of that portion of the pile contiguous to the rupture being no stronger in its resistance to crushing stress than if the pile were reinforced with longitudinal bars only. In other words, spiral reinforcement depends almost entirely for its effectiveness upon its continuity, whereas band reinforcement, being made up of a series of units, does not allow the compressive strength of the pile to be affected except locally by the breaking of a band.

Tests have shown that while spiral or band reinforcement increases the crushing strength of the column, the shortening due to deformation is very great at a comparatively early period of the load application—so much so that it would seem hardly good practice to base the safe strength directly on the breaking strength. This early deformation appears to be about equal to the maximum for plain concrete. Upon the increase of the load the

failure of the concrete is prevented by the hooped reinforcement, but the concrete continues to expand laterally; thus the elasticity of reinforced-concrete piles depends upon the strength and elasticity of the hooped reinforcement. It has been found that hooped reinforcement—while giving the necessary elasticity to columns or piles, and postponing failure beyond the time when the concrete shell outside the reinforcement has failed by cracking and peeling—does not increase the stiffness under comparatively low loads.

F. H. FRANKLAND.

Bridge Engineer, Highway Dept., Calcasieu Parish, Lake Charles, La., June 5, 1914.

Floods in Texas Since December, 1913

SIR—Since the disastrous floods of December, 1913 (described at length in my article in ENGINEERING NEWS, May 21, p. 1116), Texas has suffered another, but less severe loss by a series of heavy rains which began on Apr. 21 and continued at close intervals until June 1. The rainfall for May, 1914, averaged 7.68 in., which is 0.61 in. more than the average for June, 1899, which heretofore was the wettest month of record. Until the latter part of April the weather was about right for the farmer and prospects for bumper crops were excellent. A temporary let-up of precipitation occurred during the week ending May 11, which was promising at the time, but did not appear to help much. Heavy rains set in again on May 12 and after that date farm work came to a standstill.

The soil was too wet for cultivation and roads for the most part were impassable. In some parts land was badly washed, resulting in much loss of crops; in others, weeds and grass made rank growth and injured the crops, especially corn and cotton, and a large acreage will have to be replanted. Railways suffered from washouts and softened roadbeds.

All streams from the Rio Grande to the Sabine were more or less flooded, but the runoff was smaller than the amount of precipitation would indicate, and it is probable that the rank growth of weeds and grass prevented or at least retarded drainage into the main channels. There were strong fluctuations in the streams and at many stations flood stages were attained several times during the month. The stages were generally well below high-water mark, but there was much apprehension among the farmers of the lowlands.

The damage from the flood so far reported aggregates $1,750,000, and is likely to be much greater, as the returns are far from complete. Of this amount $405,000 was reported from the Trinity; $707,000 from the Brazos; $[illegible] from the Colorado and $[illegible] from the Guadalupe Valley; and the remaining $1[illegible] from other watersheds, and from a small per cent. of railway and telephone companies. There were 11 deaths by drowning in the swollen streams. Savings effected from warnings, so far as reported, amount to $[illegible]. Loss of live stock was small.

While pessimistic reports were received from many sections of the state during the rainy period, the outlook in the Panhandle and West Texas is promising. Ranges were reported never better; cattle fattening, and small grains in good condition; and now, that favorable weather has set in, the soil cultivated and much cotton and corn replanted, hopeful reports are coming in from nearly all sections.

So far as known the levees which were injured or destroyed by the December floods have not been rebuilt; but the matter is being agitated in the press, and the Reclamation Department of the state is receiving applications to furnish surveys and hydraulic information. Arthur A. Stiles, State Reclamation Engineer, in a letter to this office stated his belief that the tendency will be to give more careful attention to engineering details in rebuilding these levees than seems to have been exercised when they were first built.

B. BUNNEMEYER,
Section Director.

Local Office of U. S. Weather Bureau,
Houston, Tex., June 25, 1914.

A Mexican Engineer on International Relations

SIR—Owing to the irregular postal service, due to the situation prevailing in this country, it is only lately that I received ENGINEERING NEWS of Apr. 30. The interest which I always find in the editorials was considerably increased when I found that the title of one of them was "War with Mexico."

For many years I have constantly read ENGINEERING NEWS, as I consider it to be the first engineering publication in the United States and, most certainly, one of the best in the world. For this reason I esteem it as a safe guide in professional matters, as well as one of those old friends which we love because we know they are good. I fancy that I am intimately acquainted with its editors, although I have never seen them, and although they belong to another race, talk a different language, profess a different religion, have different habits, are inspired, perhaps, by different ideals and their hearts beat under different sentiments. At the same time, they are in communion with myself because of our common high regard for the engineering profession, and because of their strict proceedings and the nobility of their aims. We are all members of the great human family, and honest men of every nationality must stand together in defense of righteousness and truth. For all of these reasons I venture to write you to tell you the impressions made on my mind by that editorial entitled "War with Mexico."

I did not find—nor did I expect to find—a single word of sympathy for the people which struggles in such anguish for the solution of their tremendous political and social problems, nor did I find a single reproach to the American Government for its aggressive action toward a weakened people, action taken contrary to the promises of President Wilson before his arrival in power, which promises announced to the Latin-Americans the initiation of an era when the jingo would be suppressed and politics would be made subordinate to morals. But I certainly saw in the editorial "War with Mexico" the same intelligent viewpoint which has always inspired the editors of "ENGINEERING NEWS," the same sound basis in their arguments, the fair and judicial spirit which rules their discussion, and above all, the sense of honesty which characterizes the conduct of this journal.

I have always believed that the American engineers, considered as a body, represent the highest principles of probity and justice. George Washington and Abraham Lincoln devoted some of their activity to the noble profession of engineering. I have been personally acquainted with many engineers who are your fellow countrymen and I hold in high esteem their talents as engineers and their qualities as men. Some of the men who stand in the first rank of American engineers have lived in Mexico at some time and undoubtedly their hearts beat in sympathy with this hospitable land which tendered them every kind of favors and courtesies: A. M. Wellington, Captain Jas. B. Eads, E. L. Corthell, Howard and James Schuyler.

The high opinion I always held of the Yankee engineer has been strengthened by the wonderful address of Prof. George Fillmore Swain, Past-President of the Am. Soc. C. E., which was read at the 45th Annual Convention of the Society, held in Ottawa, Ontario, in the month of June, 1913. When a corporation has such eminent members as Prof. Swain, we can be sure it will always go forward in the right track.

As a general rule, the engineer (the genuine engineer, not the man who empirically carries on the profession), due to his knowledge of exact sciences, physical and natural, as well as to his intimate touch with nature, loves truth and justice and right, and hates deceit and hypocrisy. For this reason such a man everywhere stands above the common level. If in the United States, at some happy day in the future, engineers should rule over the political life of the nation, the Latin-American peoples could rest in tranquility. Such men would surely disclaim the infamous maxim of Bismarck: "Reason and Right stand on Strength." They would direct their activities through different channels as they would understand that justice and respect for another's rights are the firm foundation for the moral greatness of nations, the only one that can last through centuries.

Turning to another subject: Whenever, in any country, foreigners live and prosper during peaceful and orderly times and enjoy every kind of security for their honest industry they are bound to suffer the consequences of disturbances in connection with any struggle for the solution of the problems connected with the internal life of the nation and the settlement of the basis of civilization. According to the sound principles of international right and justice, a powerful government must not interfere with the internal differences of another country, nor even exact from it any claims for his citizens who have suffered damage, and this will assuredly happen when moral law rules in the world.

You know well how General Sherman's army devastated the country in his triumphal march throughout the Southern states, at the time of your Civil War. You know also that the Federal Government did not pay any claims on account of this damage either to Americans or to foreigners. When England exhibited its claims, the answer was the most round refusal.

At the moment I write these lines I do not know the result of the Niagara Falls Conference, but be it what it may, and whatever the destiny reserved to this country, weakened and impoverished by nearly four years of civil war, and held by an extraneous hand which hinders the solution of its difficult social problems, I will always keep in good remembrance the honesty and fairness of Engineering News, in reference to the possibility of a war with Mexico, virtues in harmony with the irreproachable conduct of that journal which has won its great reputation.

L. Perez Castro,
M. Am. Soc. C. E.

Box 1354, City of Mexico,
June 4, 1914.

Unit-Stresses for Steel Highway Bridges

Sir—Recently, while designing several highway bridges, the writer noticed that different specifications give widely varying results, although all are supposed to give a bridge of the same capacity.

One of the bridges has a span of 250 ft., 20-ft. clear roadway, brick pavement on a reinforced-concrete slab. The stresses in the bottom chord at the center of the span are dead-load 411,700 lb., live-load 153,000 lb. The net section required, etc., according to several specifications is shown by the accompanying table.

TABLE OF UNIT STRESSES FOR STEEL HIGHWAY BRIDGES

Specification	Tension Unit-stress live load	Tension Unit-stress dead load	Unit shearing stress shop rivets	Net area required	Number ⅞-in. shop rivets required in single shear	Impact
Cooper's Highway '09	12,500	25,000	10,000	28.7	94	No impact
Ketchum	16,000	16,000	12,000	37.9	84	$*I = \frac{S \times 150}{L+300}$
American Br. Co.	17,000	17,000	12,000	35.5	84	25% live-load
Osborn Eng'g Co.	22,000	22,000	10,000	27.6	101	$*I = \frac{S \times S}{S+D}$
C. C. Schneider	16,000	16,000	12,000	37.9	84	$*I = \frac{S \times 15}{L+300}$

*I = impact stress. S = liveload stress. D = deadload stress.
L = loaded length, ft.

It seems to the writer that this wide discrepancy should be eliminated and standard unit-stresses adopted. It also seems reasonable that where the dead-load is large in proportion to the live-load a higher unit-stress might safely be used than where the dead-load is comparatively small.

It would also seem reasonable to make little or no allowance for impact where you have a concrete-slab floor.

E. P. Knollman.

Columbus, Ohio, June 20, 1914.

A Highway Water Supply—A very unique feature relative to the Manila-North Road, unique when the highways of the world are considered, but not unique in the Philippine Islands, is the copious supply of excellent artesian water flowing at its side. The traveler will not find it necessary to trouble the housewife for a drink of water, nor the cantina nor the hotel, neither will he find it necessary to trespass upon private property to reach water. The Bureau of Public Works has drilled hundreds of these wells, and several of the provinces have purchased well-drilling machines in order to extend the well system more rapidly. Nearly every town has several of these wells and generally one may be observed at the roadside every few minutes as the traveler passes along. The water is pathogenically pure, clear, sparkling, cool and flowing, which conditions are a natural sequence after the waters have fallen upon the distant and forest-covered sierra, and have percolated for miles through the porous stratum to the perforation made by the bit of the well-drilling machine. Thus, it may be observed that ample facilities to obtain potable water exist for man and animal, and for motor cooling. Previously, it was stated that the artesian wells were not unique relative to this main trunk line. They are also being drilled by the side of the second- and third-class roads, not only in the plains region of central Luzon, but throughout the archipelago.—"Quarterly Bulletin," Bureau of Public Works, Philippine Islands, Apr. 1, 1914.

Timbering in Open Cut for Fourth Ave. Subway, Brooklyn

The collapse of the timbering in the excavation for the new Fourth Ave. subway between 76th and 77th Sts., Brooklyn, N. Y., at about 9 a.m. on June 23, dropped a 10-ton stiffleg derrick mounted with hoisting engine on an 8-wheeled truck to the bottom 30 ft. below. When completed, this section of the subway will be the 76th St. station; hence the cut is about 17 ft. wider than between stations. At this point the width is about 55 ft. and the depth to subgrade 30 ft.

The soil is mixed sand and clay and quite firm. The 8-in. timber sheet piling (not tongued and grooved) which retains it, is braced every 10 ft. by a bent built of four tiers of transverse braces, which extends entirely across the cut, butting against the wales of the sheet piling on each side. Between the several tiers at irregular intervals wood posts are set. Further stiffening against buckling is provided by two lines of 3x8-in. longitudinal bracing. The transverse braces and posts are, for the most part, 10x10-in. Fig. 1 shows the method of bracing the sheet piling.

A traveling derrick, located approximately as shown in Fig. 1, was working ahead, removing with a 1-cu.yd. dump bucket the lower 15 ft. of earth. The traveler was built of four longitudinal 12x12-in. stringers, mounted on 8 steel wheels, four per side, on a track of about 20-ft. gage. A number of wood beams placed at right angles to the stringers carried the flooring, upon which was mounted the derrick (in front) and a shanty containing the hoisting engine. The derrick had a 40-ft. boom.

Figs. 2 and 3 show conditions subsequent to the collapse. The mass of wreckage gives little indication as to the direct cause of the failure. Just prior to the acci-

Fig. 2. View of the Break from the West

[illegible]

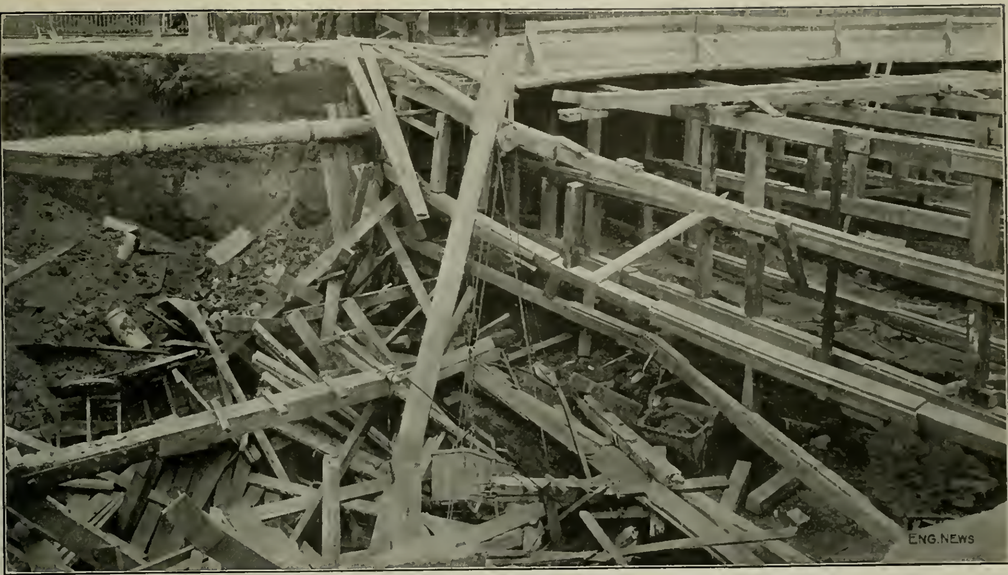

Fig. 3. The Wrecked Derrick and the Timbering at Upper Face of Break

Fig. 4. General Method of Bracing Sheet Piling in 15-Ft. Cut

dent the traveler had been moved forward about 20 ft. and was again operating. Three bents, together with the sheet piling on one side, collapsed. The fourth bent on the upper side of the break sagged, and several of the posts were displaced, as shown in Fig. 3.

It is possible that earth pressure caused one of the braces to knuckle, as the longitudinal bracing was flimsy. On the other hand, the timbering carried a live load in the form of a derrick; it is, therefore, possible that one of the bottom posts supporting the lowest brace in one of the bents collapsed, due to undermining, either from the digging operations or from ground water. There is no information that a moving bucket struck the timbering nor that the derrick itself failed.

At the time, 20 men were working down in the cut (12 muckers and a timbering gang of 8 men). One man was killed, another died a few days later, and five others were injured. A team and truck fell into the cut, killing one of the horses. Three 10-ft. lengths of a 16-in. water main were left entirely without support (Figs. 2 and 3): but the main did not break. The water, however, was ordered cut off, and there was no pressure from 9 a.m., until 5 p.m. In the meantime the main was stiffened by suspending from a steel I-beam.

Since the Collapse

A jinney-winch, to be caused by the steel erectors, was fortunately at hand and was pressed into service. It was installed just back of the collapsed portion of the timbering, and proceeded to retimber the break, working forward. On June 26, this work was nearly completed. To continue the mucking a new traveler has been erected of the same design as the old, but on the opposite side of the break. This was done so as not to interfere with the operations of the jinney-winch.

The new traveler was placed in service June 30. It moved backward on the timbering of the first cut, which is only 15 ft. deep. The transverse bracing here is of the same character as in the deeper cut, but there are only two cross braces per bent instead of four. The spacing between bents is still 10 ft.

This method of moving the traveler is not so satisfactory as was the old, where it moved on the final timbering; but the total duration of the work will be shorter than would be the case with the jinney-winch taken out of service and moved to the opposite side of the break. The new traveler could not be erected back of the winch,

because of the interference of a temporary highway bridge.

METHOD OF EXCAVATING AT 76TH ST.

The first cut, of 12 to 18 ft., was made with a steam shovel traveling on the ground. It was the original intention to make the second and final cut with a locomotive crane traveling on the bottom of the first cut. Failure to deliver the steelwork for the subway caused this plan to be abandoned; the locomotive crane merely removed

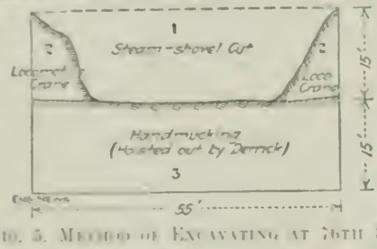

FIG. 5. METHOD OF EXCAVATING AT 76TH ST.

(The first cut was made with a steam shovel, side slopes removed by a locomotive crane traveling at 15-ft. sublevel. The next cut will be mucked by hand and earth removed by a derrick traveling on top of timbering.)

the side slopes left by the shovel. The cut was then timbered, and work transferred to other portions of the line. Had the work proceeded without interruption at this point, this section might have been completed several months earlier.

When it was decided to reopen operations here, the presence of the timbering made the employment of the locomotive crane impracticable. A traveling derrick was, therefore, erected on the timbering, and the work proceeded until the unfortunate accident described. The mucking was done by hand and the material hoisted by the derrick. Three buckets in rotation were employed. About [illegible] ft. of mucking remains to be done here. The derrick had been in use several weeks on this class of work.

The Degnon Contracting Co., New York City, was general contractor on this section. The subcontractor was Carpenter, [illegible], Inc., Roanoke, Va.

Annual Convention of the American Railway Master Mechanics' Association

The 47th annual meeting of this association was held at Atlantic City, N. J., June 15 to 17. Below is a brief account of the proceedings supplementing that given in the "Society Proceedings" column of last week's issue.

MECHANICAL STOKERS FOR LOCOMOTIVES—This subject is of growing importance with the increase in train loads and power of locomotives, and the committee's report showed that the mechanical stoker is no longer an experimental machine. At the present time there are about [illegible] stoker engines, [illegible], [illegible] Crawford stokers, and a few of half a dozen other designs. The average mileage per machine failure (exclusive of failures due to improper handling) has been about [illegible] miles on the Norfolk & Western R.R. and [illegible] miles on the Baltimore & Ohio R.R.

The mechanical stoker is not to be considered primarily as a coal-saving device, but rather as a power-increasing device, and the general consensus is that the stoker engines can haul heavier loads than hand-fired engines. Further, the stoker can work to full efficiency throughout the run, while a fireman's efficiency falls off as he becomes tired. But the stoker needs to be handled carefully to maintain the full efficiency and power of the engine and to avoid excessive coal consumption. The discussion strongly indorsed the position taken by the committee.

SUPERHEATER LOCOMOTIVES—The report dealt with the results of various changes in the form and dimensions of superheaters (Schmidt type) on the same engine, as shown by experiments on the locomotive-testing plant of the Pennsylvania R.R. It dealt also with the question of piston packing and rod packing that will resist the action of superheated steam. A paper by H. W. Coddington (independent of the report) described road tests on the Norfolk & Western R.R. with engines having Schmidt superheaters, but with and without firebrick arches. The former showed a saving of 5% in coal consumption.

FUEL ECONOMY—This report constituted a digest of replies to a list of questions. It advocated the purchase of coal by specification, the keeping of accurate coal-supply records, the use of good feed water (with treatment if necessary), the reduction of waste due to coal falling from tenders and cars, the keeping of engines in proper condition, and a full cooperation between enginemen and firemen and between these men and their superior offices. It suggested also that the use of pulverized coal may effect considerable economy.

In regard to good feed-water, the report stated that the saving due to reduction in scale and decreased boiler maintenance will pay for the cost of treating the water. The discussion tended to show that while scale is undesirable it has practically no effect upon fuel consumption. As to the selection of good coal, another view presented was that it is better to provide for the effective use of the poorer grades of coal.

SMOKE PREVENTION—Steam jets and blowers are used by a number of roads, and the former are considered to be very effective. One road uses a perforated ring blower around the top of the stack. The mechanical stoker and the brick arch tend to reduce smoke, but the effect of the superheater in this respect is varied. Only one road has introduced apparatus for dealing with the smoke at roundhouses, and this smoke-washing plant (on the L. S. & M. S. Ry., at Chicago) was described in ENGINEERING NEWS, May 15, 1913. The various devices used on the engines are efficient, but the men must be trained as to their proper use. The subject is of importance since so many municipalities are taking up the question of abating the smoke nuisance.

TRAIN RESISTANCE AND TONNAGE RATING—The committee recommended certain car-resistance diagrams and tables for use in computing the tonnage rating (a) for track having heavy rails and a high degree of maintenance, and (b) for lighter track with medium maintenance. The figures recommended in the report were objected to as being based on insufficient investigation, and the report was referred back to the committee for further consideration.

STEEL ALLOYS AND HEAT-TREATED STEEL—The committee stated its opinion that the manufacture of plain carbon and alloy steel to be quenched and tempered will eventually be developed to the point where such material can be used in designs involving much higher unit working stresses than are possible with untreated or an-

nealed plain carbon steel, with a consequent reduction in the weight of parts.

Locomotive Headlights—A voluminous report described a number of road and laboratory tests, and gave the rules of various railways and the requirements of various public authorities. The conclusions were as follows: (1) the headlight must have a beam candlepower not greater than 3000 cp. at 500 to 1000 ft. from the engine, in order to avoid such intensity as would interfere with signals (block, hand, etc.), and temporarily blind an engineman looking into it; (2) the headlight should have an apparent beam candlepower of not less than 450 to 500 cp. at 500 to 1000 ft. from the engine (and 30 to 350 cp. at distances of 50 to 400 ft. from the center line), in order to give sufficient illumination to show landmarks, crossing and other signs, and to enable the engineman to readily perform his duties at terminals, etc.

The discussion brought out the disadvantages and incidental dangers of high-power headlights. It was suggested that one reason why enginemen have advocated such lights is that they give a better side illumination, enabling signs, etc., along the right-of-way to be seen readily. This side illumination or lateral spread of the light is of more importance than a powerful beam of light directed straight ahead.

Other Reports and Papers—Other committee reports were as follows: (1) Rules for road and laboratory tests of locomotives; (2) Revision of standards and recommended practice; (3) standardization of tinware (oil cans, buckets, etc.); (4) train brake and signal instructions. The committees on boilers and safety appliances made no reports. There were also other papers as follows: "Flange and Screw Couplings for Injectors," by O. M. Foster (L. S. & M. S. Ry.); "Electric Motors in Railway Shops," by B. F. Kuhn (L. S. & M. S Ry.), and "The Minor Mechanical Organizations," by Angus Sinclair.

Annual Meeting of the Master Car Builders' Association

The 48th annual meeting of this association was held at Atlantic City, N. J., June 10 to 12.

In his presidential address, M. K. Barnum (B. & O. R.R.) referred to the necessity of equipping freight cars promptly with the safety appliances called for under the present laws. The building of wood passenger cars has practically ceased, and many roads are applying steel underframes and steel ends to the existing cars, while much work has been done in improving the older freight cars by applying steel underframes and ends and heavier draft gear. He advocated standard dimensions for 40-ft. and 50-ft. freight cars, but pointed out that when the American Railway Association some years ago adopted a standard 36-ft. box-car the traffic departments at once began to demand special sizes. At the present time very few of these "standard" cars are built.

Car Construction—The principal feature of interest in this report was its recommendation of a minimum cross-sectional area of 24 sq.in. for the steel center sills of new cars. H. H. Vaughan (Can. Pac. Ry.) opposed this as being too high, he having had satisfactory results in four years' service with a number of cars having only 20 in. of metal. Others thought four years too short a time, and reference was made to cars having 35 to 40 sq.in. in the sills. The matter will go to letter ballot.

The question of standard design of box-cars also produced decidedly opposite views, some considering that car design is at present in a state of evolution and that standardizing would be premature, while others thought it time to take the matter up, especially as it would be some years before any standard design could be submitted and adopted. The statement was made that the American Railway Association has been making an investigation as to interior dimensions of box-cars, with a view to adopting some standard, and will submit the matter to the Master Car Builders' Association.

Retirement of 20- and 25-Ton Cars—This committee recommended that cars of less than 30-ton capacity should not be accepted in interchange service after Oct. 1, 1916, and this will be submitted to letter ballot. There were the usual objections as to such a move, both by railway men and private-car owners, and it was pointed out that many 30-ton cars may be of weaker construction than the lighter cars. But the weight of opinion was to the effect that these latter cars are a source of expense, trouble and danger.

Tank Cars—There is some controversy as to the handling and testing of the older tanks, and the committee did not favor the unrestricted transfer of such tanks to new steel underframes, especially where inflammable liquids are to be carried. The owners of such tanks desire a lower pressure test than the 60-lb. standard for new tanks, and the committee suggested a 40-lb. pressure for tanks built before 1903, but prohibiting them from carrying inflammable liquids. A "collision test" indicated that a tank which will stand 20-lb. water pressure without leaking will withstand the shocks acquired in transportation when filled with a liquid of the same viscosity as water.

Car Wheels—The subject of the contour of chilled cast-iron wheels in relation to frog and guard-rail flangeways has been submitted to this association and the American Railway Engineering Association by the American Railway Association, but the committee reported that there is not yet sufficient information as to the latest design of wheel to warrant any recommendations. It was stated, however, that the U. S. Bureau of Standards is about to make an investigation as to the manufacture and design of wheels of this class.

Car Trucks—The committee had been instructed to submit limiting dimensions for cast-steel truck frames for 40-, 50- and 70-ton cars. As such frames are generally covered by patents it was considered impracticable to recommend definite designs, but limiting dimensions are necessary to provide for applying and interchanging the standard bolsters designed and submitted by the committee. The report will be sent to letter ballot but th section relating to truck springs will be referred to the committee on specifications and tests.

Brake-Shoes and Brake-Beams—The committee reported the conclusion of the extended series of tests on brake-shoes at Purdue University, bringing the earlier tests into relation with the more recent tests at high speeds and pressures. It reported also that greater attention should be given to the hanging of the brake-beams, as a very large proportion of the defective beams removed show that the trouble is due to improper hang-

ing. This statement was strongly indorsed in the discussion.

COUPLERS AND DRAFT EQUIPMENT—The committee reported satisfactory experience with the road-service tests of the new experimental couplers, which prove to be much stronger than the present types. After considering the various designs submitted by manufacturers as embodying the requirements agreed upon between the committee and manufacturers, two were selected for the final elimination trial in service. In the discussion it was pointed out that railway officials should understand that while the new couplers are larger, heavier and more costly, they are a necessity to meet present-day traffic conditions.

CAR-DUMPING MACHINES—The committee reported that as a result of its 1913 report on the damage to cars by these machines, the manufacturers are modifying the designs and have prepared plans for necessary changes in existing machines. Further, it appears that no new machines of the solid-floor type will be built, all being of the movable platen type.

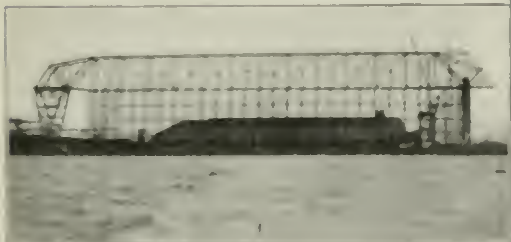
OTHER REPORTS—The reports of other committees were as follows: (1) Train brake and signal equipment; (2) safety appliances; (3) train lighting (design of axle-carrying pulleys); (4) rules for loading materials on cars (including brick, drain tile, etc.); (5) inspection of box-cars; (6) specifications and tests of materials; (7) standards and recommended practice; (8) rules of interchange; (9) prices of labor and material for car repairs.

The officers for the ensuing year were given in our issue of June 25, 1914.

Storm Damage to Steel Structures at Duluth

The accompanying views show a part of the damage done at the coal docks at Superior, Wis., during the tornado of May 25, 1914.

Figs. 1-3 are views taken at the Northwestern Fuel Co., Dock No. 1, located on Superior Bay. Here the largest coal-handling bridge in the world was blown down by the wind and the rig is a total loss. The span of the bridge was 552 ft. with a height from the floor to the top chords of about 140 ft. Fig. 1 shows the huge bridge standing before the storm. This view was taken in June, 1913, while the construction work was going on and when most of the falsework was in place. The bridge was designed and built by the Heyle-Patterson Co., who have already been awarded a contract for a duplicate machine to replace it. Fig. 2 shows the destruction at the shear end of the bridge and the manner in which the steamer "Wm. A. Rogers" was pinned under the apron. The operator of the bridge was just hoisting the bucket, which was located at the left of the view, out of the hold of the boat when the bridge started to move, and when it fell he was caught under the wreckage and almost fatally injured. Fig. 3 shows the manner in which the pier end of the bridge fell and gives a clear view of the way part of the trolley runway lies. The brakes, clamps and chocks held this end of the bridge, but under such an excessive strain the shear



FIGS. 1-3. NORTHWESTERN FUEL CO.'S DOCK NO. 1, SUPERIOR BAY, WIS.

(FIG. 1. [illegible]. FIGS. 2 AND 3. [illegible] BY TORNADO MAY 25, 1914.)

FIG. 4. WRECKAGE OF ISLAND CREEK COAL DOCK NO. 2, ST. LOUIS BAY, SUPERIOR, WIS.
FIG. 5. WRECK OF NORTHERN COAL & DOCK CO.'S COAL-HANDLING BRIDGE, NORTHWESTERN DOCK, SUPERIOR, WIS.

end moved for some distance before the whole structure overturned.

Fig. 4 shows wreckage at the Island Creek Coal Dock No. 2 on St. Louis Bay, Superior. The clamps and chocks in this case also could not hold the big bridge and it skidded for almost 25 ft. before going over. A duplicate of this bridge is to be built by the Brown Hoisting Machinery Co., of Cleveland, but none of the mechanism, etc., of the old rig can be used.

Fig. 5 is one taken of the wrecked bridge at the Northern Coal & Dock Co. dock, located almost next to the Northwestern Dock on Superior Bay. Here also the destruction is complete and it has been found impracticable to use either the steel or machinery in the reconstruction work.

The damage from the storm undoubtedly will run well over $500,000. The wind was from the southwest and although the Weather Bureau recorded a maximum velocity of 65 miles per hour, the extreme velocities must have been much greater than that in the storm path.

Progress on the Alaska Railway Surveys*

Eleven parties are now entering the field under the direction of the three commissioners, William C. Edes, Lieut. Frederick Mears and Thomas Riggs, Jr. It is planned to gather data over some 1100 miles of line during the summer season.

Six locating parties will make location surveys over the Seward-Fairbanks route via Susitna Valley and Broad Pass. A reconnaissance party will go over the route of the proposed Kuskowim extension via the Skwintna, while other parties will work in the vicinity of Knik and Turnagain Arms, Matanuska, Portage Bay and Seward.

The three locating parties between Broad Pass and Fairbanks will be under the direction of Mr. Riggs. Lieut. Mears will direct three parties in the Susitna Valley up to Broad Pass, and Mr. Edes will have charge of the parties adjacent to the coast. The headquarters will be at Ship Creek on Knik Arm and an office will be kept open at 1108 Alaska Bldg., Seattle, Wash.*

*From D. L. Reaburn, Locating Engineer, Skagway, Alaska.

*For further data on the Alaska Ry. routes the reader is referred to "Engineering News," Mar. 20, 1913, containing an abstract of the report of the Alaska Railroad Commission.

The Railway Mileage of the World was 670,000 in 1912, according to a recently published report of the Prussian Department of Public Works. The western hemisphere contains more than half of this mileage, the United States, with almost 245,000 miles of railways, has no rival, Germany is second with 38,000 miles. Belgium, the most densely populated nation, has the highest record in proportion to area—47 miles of railways to 100 sq.mi. of territory. Australia, with the thinnest population of civilized countries, has the record in proportion to population. The United States has 6.92 miles of railways per 100 sq.mi.; while Europe has 5.63 miles per 100 sq.mi. Railway systems of the five great geographical divisions, compare in miles of operated line as follows:

	1912	1911	Gain
Europe	212,427	210,131	2,296
North and South America	343,557	333,376	10,181
Asia	66,483	65,107	1,376
Africa	26,478	25,103	1,375
Australia	21,578	20,089	1,489
Total	670,523	653,806	16,717

Annual Meeting of the Society for the Promotion of Engineering Education

The 22nd annual meeting of the Society for the Promotion of Engineering Education was held at Princeton University, June 23-26. For many years this Society thought it necessary to hold its annual summer convention at the same place and at about the same time as some one of the national engineering societies, so that those of its members who desired to attend the national society convention might have a double inducement to attend. The experience at Princeton this year, however, proved that this society is entirely able to hold a successful convention by itself. Over 200 members were in attendance, and the regularity with which the daily sessions were attended and the active discussions which took place on most of the papers presented would have done credit to societies of much larger membership.

Most of the papers presented at the meeting, aside from the committee reports, had been printed in advance in the Society's journal, so that the time was spent in discussion and not in the reading of long papers. One or two excellent features in the conduct of the convention which we have never seen elsewhere are now followed by this Society and are well worthy of note by those interested in the successful conduct of engineering meetings. In giving out badges to those in attendance upon a convention it has become usual now to have the wearer's surname on the badge. We believe the American Society of Mechanical Engineers was the first society to start this custom a quarter of a century or more ago. The wearing of a surname printed in plain letters on a badge attached to the lapel of the coat has saved many thousand embarrassments without doubt to men who on recognizing a familiar face have searched their memories in vain for the name of the person recognized. The Engineering Education Society has now inaugurated an improvement on this excellent custom. The badges worn at the Princeton convention had marked upon them the wearer's initials as well as his surname, and also the name of the college with which he was connected or his place of residence. In practice this is found to add a great deal to the sociability of the members and to the facilities for making acquaintance. To read plain "Jones" on the lapel of a man's coat may not place him at all definitely, but to read "Ezekiel Jones, M.I.T." at once gives information on which to hang conversation and acquaintanceship.

Another feature that adds very much to the interest of the discussion is the following: A large blackboard is placed at the front in view of the audience. As soon as a member rises to take part in the discussion, the Secretary writes in large letters on the board the name of the member and also the institution with which he is connected. Among the features of the meeting were a series of papers on "Methods of Teaching Mathematics," which brought some striking differences of opinion, and reports of some recent experiments on the rating of engineering students according to their character and personal qualifications which have been made at the University of Cincinnati and at Purdue University.

Besides the technical program presented in the four days' session, various social events were arranged for the visitors' pleasure, including a reception by President and Mrs. Hibben, a lecture on the great meteor crater of Arizona, and the annual dinner of the Society on Thursday evening, at which the President, Dean Gardner C. Anthony, of Tufts College, delivered the annual address.

The following officers were elected for the ensuing year: President, Anson Marston, Dean of the Division of Engineering, Iowa State College, Ames, Iowa; Vice-Presidents, Henry H. Norris, *Electric Railway Journal*, New York, and C. Russ Richards, Acting Dean of the College of Engineering, University of Illinois, Urbana, Ill.; Secretary, F. L. Bishop, Dean of the School of Engineering, University of Pittsburgh, Pittsburgh, Penn.; Treasurer, William O. Wiley, John Wiley & Sons, New York; members of the council, R. H. Fernald, A. H. Fuller, A. M. Greene, Jr., E. V. Huntington, Vladimir Karapetoff, D. C. Miller, W. M. Riggs. The reports of the various officers showed that the society is in a flourishing condition; the individual membership is now nearly 1100 and the institutional membership about 50. The council recommended that the 1915 meeting be held in the Middle West.

Annual Convention of the American Institute of Electrical Engineers

The 31st Annual Convention of the American Institute of Electrical Engineers was held June 22 to June 26, at the Hotel Pontchartrain in Detroit. In the annual address by President C. O. Mailloux at the opening session, Mr. Mailloux congratulated the Institute on the extraordinary progress which had carried it, the youngest of the great National Engineering Societies, to a position where it could claim precedence not only in number of members and of local sections, but also in the importance of its technical work.

The field of electrical application is rapidly enlarging, and unless this enlargement should result in a loss of solidarity through the splitting off of societies of a too specialized character, the greatest work of the Institute is still before it.

President Mailloux then spoke at length upon the duties of the engineer to society. The engineer has been prone to regard his duties with too narrow a vision. Not enough emphasis has been placed upon the broader development which would fit the prospective engineer for the position he should hold in the public life.

In recent years no other profession has had so profound an influence upon the advancement of civilization as has that of the engineer, but he has been too busy with the details of his task to realize his mission or to impress it upon the public mind.

The public has long since come to demand the services of a jurist in important judicial positions and of a physician when questions of health and sanitation are under consideration. It is equally necessary that its engineering problems be solved by engineers. Now its engineering commissions are largely filled with lawyers, politicians and merchants. This situation must be changed. Every year, with the increasing complications of modern life, there is more and more need for the engineer at the helm.

Mr. Rushmore, of Schenectady, in discussion of the address, said that the engineer instead of being on the Public Service Commissions and in the responsible civic po-

sitions where he should be was now usually employed to serve and instruct the laymen Commissioners and public officials. The man who knows and is competent is too often under and dominated by the man who does not know and is incompetent.

The first technical paper of the session was upon Electric Heating as Applied to Marine Work. The authors were Lieutenant C. S. McDowell and D. M. Mahool, who have been conducting extensive tests upon this subject for the Navy at the Brooklyn Navy Yard. It was brought out in the paper and the discussion that for most cases the radiant heater depending upon the radiation from large lamps or red-hot wire was most satisfactory and efficient. and that for moderate temperatures and auxiliary heating, the cost of its operation was not prohibitive. However, as showing the impracticability of using electric heat for general use, it was shown that at five cents per kilowatt-hour the cost for heating a medium-sized house would be about $2000 per annum, using the data given in the paper. An interesting point also brought out in the discussion was that furnaces given a coat of whitewash would have a higher surface temperature but would radiate less heat than those unpainted.

Perhaps the most noteworthy development in the application of electricity which was described at the convention was that of the gyroscopic compass as described in the paper of H. C. Ford, of Brooklyn, N. Y. This application of the well known gyroscope has been developed by a pioneer electrical inventor and a charter member of the Institute, Elmer A. Sperry. The compass requires no corrections such as are necessary with the magnetic compass and it is absolutely permanent. Its use has become general in the navy and it is beginning to be adopted by the merchant marine. The successful use of large gyroscopes for stabilizing boats and preventing their rolling was also described and several other uses were touched upon.

The evening session on Tuesday was under the direction of the Industrial Power Committee and the Chairman. Rudolph Tschentscher, of the Illinois Steel Co., South Chicago, presided. Three papers were read, all relating more or less to the steel industry.

Direct-current motors for coal and ore bridges by R. H. McLain of the General Electric Co., Schenectady, gave valuable technical data with regard to the characteristics of motors for this use and their operation. Mr. McLain took up particularly the relative values of acceleration and running speed needed for various length and times of travel. The trolley accelerations vary from 1.5 to 2.5 ft. per sec. and car speeds run as high as 1500 ft. per min. Series motors with dynamic braking are used, though a weak shunt field may be added to accelerate the braking action. For hoisting, use is made under varying conditions of either series, compound or shunt-wound motors, the series being used for the lowest and the shunt for the highest speeds. On low-speed hoists, dynamic braking is used in lowering the empty bucket.

Transmission Lines

On Thursday morning a meeting was held under the direction of the Engineering Data Committee with P. H. Thomas, Consulting Engineer, of New York City, Chairman. "Data relating to high-tension transmission systems" was the subject of a subcommittee report which was prepared by Mr. Thomas. It is an analysis of the reports made by 25 power companies in reply to inquiries sent out to about one hundred companies operating at 25,000 volts or over. Those reporting included six companies working at 100,000 volts or over, 4 at about 85,000 volts, 10 at about 60,000 and 4 at 25,000 to 50,000 volts. One of those now rated at 85,000 is designed to eventually operate at 140,000.

A large collection of valuable technical data concerning the characteristics and operation of high-tension lines was given, largely in tabular form. Some points of general interest are the following: although one span on the lines of the Pacific Gas & Electric Co. is mentioned as of 4427 ft., the largest span described is 3200 ft. in the line of the Mississippi Power Co. and crosses the Missouri River. A steel core cable is used and the highest tower is 230 ft. The greatest total mileage is that of the Pacific Gas & Electric Co., California, with 1260 miles. Standard tower spans vary from 400 to 800 ft. Very little deterioration of any kind was reported, though it was brought out in the discussion that one Western company had just discovered bad pitting of the copper wires at certain points where in contact with the insulators. This line had been in use 11 yr., most of the time at 60,000 volts. Nearly all companies work on one of two lines on the same pole or tower while the other line is alive. Eleven companies use preservative treatment on their wooden poles at costs varying from 10c. to $1.50 each. The largest line-charging current reported is 250 amperes at 60,000 volts by the Pacific Gas & Electric Co. Nearly all companies have telephone lines on the same poles or towers as the power lines.

Power Plants

Wednesday afternoon the meeting was presided over by H. G. Stott, Chairman of the Prime Movers Committee and Superintendent of Motive Power of the Interborough Rapid Transit Co. The paper presented jointly by him and Messrs. W. S. Gorsuch and R. J. S. Pigott, both of the Interborough Company, was, on account of Mr. Stott's reputation as an authority, one of the most anticipated of the meeting. Its title was "The Present Status of Prime Movers."

Six subdivisions were given as follows: (1) Reciprocating steam engines; (2) steam turbines; (3) gas engines; (4) oil engines; (5) hydraulic turbines; (6) Finance and economics.

The reciprocating steam engine was disposed of in half a page as not to be considered except in very small sizes or under unusual conditions. Prime movers are to be compared as to (a) capacity, (b) efficiency, (c) weight and (d) price. Taking up first capacity and efficiency, the writers criticized the steam consumption per kilowatt-hour as being unsatisfactory when not accompanied with data as to steam and vacuum conditions. They advocate a wider use of the efficiency ratio (Rankine cycle), which is a measure of the excellence of design and which differs much less among modern turbines than the varying water rates would lead one to suppose. Curves showing the rate of steam consumption taken from actual turbines up to 30,000 kilowatts showed a minimum water rate about 12¼ lb. for a 60 cycle; 80% power factor; 175 lb. pressure; 100° F. superheat and 28.5-in. vacuum, which are taken as standard conditions. At 15,000 kw. the rate is only a small fraction of a pound higher, but below this size the rate goes up rather rapidly.

The best water rate should, for most purposes, occur at 75 to 85% of the maximum 24-hr. rating.

Curves showing Rankine-cycle efficiency ratios, with a maximum of 77% and thermal efficiency with a maximum of 20%, were given. These curves were nearly flat throughout the upper half. A similar curve for pounds per kilowatt brings the weight for 30,000 kw. down to 30 lb. per kilowatt as a minimum, and is a straight line to 15,000 kw., where the figure is 35 lb. per kilowatt. Again, the lowest cost per kilowatt ranges from about $6.60 at 15,000 kw., to $6.20, at 30,000 kw.

Taking up the gas engine, the statement is made, that over 75% of the gas-power machinery, is used with blast furnaces and natural gas. Blast-furnace engines have reached a capacity of 6000 b.hp. for a single unit of the twin-tandem type. The gas engine has an efficiency curve which rises continually to its maximum load, and thus has no inherent overload capacity. The gas engine has the advantage of fairly uniform thermal efficiency for all sizes, and this may be taken as 23.8% on a basis of kilowatt-hours at full-load rating (25.2% for brake horsepower). Guaranteed fuel consumption varies from 13,500 to 19,200 B.t.u. per kw.-hr., for producer gas, with a somewhat wider range for natural gas, and 15,000 B.t.u. for blast-furnace gas. In the matter of weight, the high temperatures and pressures involved, place the gas engine at a disadvantage when compared with steam engines. Weights are given up to 1500 kw., where the average weight per kilowatt is 740 lb., as against 58 lb. for a 3600-r.p.m. turbine. Moreover, the weight per kilowatt of the gas engine increases with size. On account of the great weights, the costs also, of gas engines are high. The curves given show an average cost for 1500 kw.-units as $71.60 per kilowatt.

There are approximately 300 installations of medium and heavy-duty oil engines in the United States, aggregating over 75,000 hp. The largest of these is 450 b.hp., although in Europe 2500-hp. Diesel engines have been built. For 19,000-B.t.u. oil, a curve is given, showing a full-load efficiency of 28.2%, on the basis of electrical output (auxiliaries not allowed for). For a 400-kw. vertical Diesel engine, the pounds per kilowatt are 750, and the curve is nearly horizontal, though it rises rapidly for the lower capacities. The cost per kilowatt, is given as $95, though the data for this figure are limited.

The best efficiencies now obtainable from hydraulic turbines are slightly over 90%. Much improvement has been made in the power per unit weight. Recent progress is toward the use of single-runner vertical-shaft turbines for low and medium heads. Weights and costs are not strictly comparable with steam and gas equipments, on account of the influence of difference of head in the case of water power.

Under the head of "Finance and Economics," a comparison is first made of different heat engines and curves are drawn, showing the comparative costs at different percentage loads of 750 kw.-units. From these curves, the following data may be derived:

Per cent. of load	Cost per kw.-hour, mills 25%	50%	100%
Steam turbines	6 3	4 3	3.2
Gas engines	9 5	5 2	3.2
Oil engines	12 0	7 0	5 0

A similar set of curves is given for the comparison of one 20,000-kw. turbine, ten 2000-kw. gas engines and forty 500-kw. oil enginets, the power in each case aggregating 20,000 kilowatts. This case is naturally still more favorable to the turbine. The cost figures at full load are: turbine, 2.1 mills; gas engine, 3.2 mills; and oil engine, 4.7 mills. In these figures, coal is taken at $3 per ton, for both turbine and gas engines, and oil is figured at four cents per gallon. Attention is called to the unsuitability of gas engines, hydraulic turbines or other apparatus with high-investment charge for carrying short-time-peak loads. The fact is also noted that the largest turbines have now surpassed the best gas engines in fuel economy at high-percentage loads. Emphasis is placed upon the reliability and low maintenance of the steam turbines, and upon their great space economy.

Cables

A paper on voltage testing of cables, by W. I. Middleton, of the Simplex Wire and Cable Co., of Cambridge, Mass., and C. L. Dawes, of Harvard University, was a highly technical discussion of the conditions met with in testing cables.

In discussing the paper, Mr. Stott stated that all the cables of the Interborough road were tested with 2½ times normal voltage at least once a year, and many of them oftener.

Edison Medal

On Thursday evening occurred the presentation of the Edison medal, always one of the most interesting events of the Institute meetings. Funds for this gold medal were provided by a number of Mr. Edison's friends on the occasion of his 57th birthday. This year, the fourth time that it has been awarded, it was given to Charles F. Brush, of Cleveland. Before making the presentation, President Mailloux sketched at some length the early history of electrical development, with which Mr. Brush was closely associated.

To show what an advance Mr. Brush had made in electric lighting Pres. Mailloux describes one of the earliest installations of arc lights where ten lights were arranged around Madison Square, each lamp being driven by a separate generator taking 2 or 3 horsepower each. It was such a condition as this, which impressed upon Mr. Brush the necessity of a better method for the operation of lamps and which led to the successful development of the series arc-lighting system. In 1881 there was exhibited at the International Exhibition at Paris, Brush apparatus built by the English Brush Company.

It was not until 1882 that the first constant potential Edison central station was built on Pearl St., New York, and already at that time hundreds of stations for the production of arc lighting were in operation all over the country. These were all very small, usually not over 15 or 20 lamps at the largest. A 50-hp. engine was a large one. The 150-hp. engine at the Pearl St. Station was mammoth. At that time, the rivalry between the Edison and the Brush system was most severe, and Pres. Mailloux called attention to the changed conditions which now after thirty years, bring it about that Mr. Brush is receiving the "Edison" medal.

Ultra-Violet Rays

On Friday morning a paper on the sterilization of water by ultra-violet rays of the mercury vapor quartz lamp, was given by Mr. von Recklinghausen, Director of the Westinghouse Cooper-Hewitt Co., Paris, France. It

is found that all the dangerous bacteria, and all their spores succumb to the ultra-violet light, if exposed to it strongly enough, for even a fraction of a second. To obtain the use of all the light, the lamp must be surrounded by the water, but it is found that if the water comes in contact with the tube of the lamp itself, the activity is greatly reduced. Also since glass is opaque to the ultra-violet rays, only quartz can be used between the tube and the water. Stirring up the water in its passage through the tank is necessary, to prevent the bacteria from hiding behind particles of the matter in the water and escaping. The largest plant now in use is at Luneville, France, and has ten lamp equipments. The water as fed to this outfit, has a germ content, sometimes as high as 1000 per c.c.; on leaving, the bacterial content is reduced down to from 0 to 10. There has been a great reduction in the typhoid-death rate in this place, the old rate ranging from 70 to 160, balanced against almost no deaths at all, at the present time. The energy consumption is very small; the largest lamp in use takes but 2½ amperes at 500 volts. From 50 to 130 kw.-hr. per million gallons is a liberal estimate of the power necessary. In answer to questions which came out in the discussion, Mr. von Recklinghausen estimated the cost at about 60c. per million gallons, including power at 1c. per kw.-hr. and lamp renewals at 30c. per million gallons. The water must not be too turbid, so that the light will be too soon absorbed by it. The Luneville plant has been in operation three years, and purifies 200,000 gallons per day.

The afternoon of Friday was devoted to a conference of the section delegates. There are at present 30 sections, and 48 University branches. The traveling expenses of the section delegates are paid, and nearly all the sections were represented at the meeting. Among other things, a resolution was passed, asking the Board of Directors of the Institute to define more exactly the relation of the section delegates to the affairs of the Institute.

The attendance was nearly 500, and the convention will long be remembered as a most successful one.

The Ficklen Patent on Steel Expansion Joints for Concrete Roads

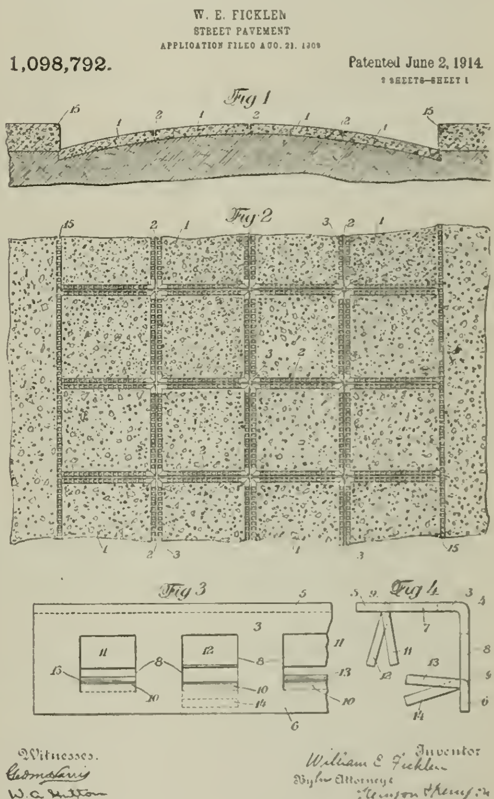
Letters have recently been sent out by the firm of Moore & Clark, Patent Attorneys, of 2 Rector St., New York City, addressed to various State Engineers and others demanding royalties on concrete pavements or roadways on account of a patent issued June 2, 1914, to Wm. Ficklen, of 2 Rector St., New York City. The letter states that "the patent broadly covers a concrete pavement supported on an earth bed and formed with expansion joints armored at their upper edges."

While the Ficklen patent was issued on June 2, the original application was filed Aug. 21, 1909. The attorneys claim that Ficklen's invention antedates the inventions of Baker, Kahn and others who have for some time been making and selling steel material for expansion joints in concrete roads, and that those who have purchased and used such joints, therefore, are subject to suit for the collection of royalties.

By the courtesy of the patentee and his attorneys, we have been permitted to examine the record of the case before the Patent Office. This record is extremely voluminous. During the five years since Ficklen filed his original application, his case has been in the hands of several different firms of patent solicitors, and the records show over forty different actions by the Patent Office before the case was finally allowed.

The patent undeniably contains broad and sweeping claims. They are typified by Claim 1, which is as follows:

1. A pavement comprising an earth roadbed, a crust supported directly on said roadbed and comprising a plurality of concrete sections of relatively large area separated from each other by expansion joints extending from the top of the pavement to the roadbed, and reinforcing means embedded in and carried by and continuing along the upper portions of the edges of the concrete sections at the joints which require reinforcement.



FACSIMILE OF MAIN PAGE OF ILLUSTRATIONS OF U. S. PATENT NO. 1,098,792

We reproduce herewith the first sheet of drawings of the Ficklen patent (which is No. 1,098,792). It will be noticed on this drawing that Ficklen originally contemplated dividing up a roadway into blocks about the size of ordinary sidewalk slabs. The words "relatively large area" did not appear in the broad claims filed with the original application, but were added in some of the numerous amendments. Possibly it was thought their addition would better sustain the claim that the construc-

[illegible] and described applied also to concrete roadways with transverse joints spaced 25 to 40 ft. apart.

Referring to Claim 4, its validity rests on the question whether Fischer was the first to combine, with the expansion joint (or dividing plane) of a section of concrete pavement, "reinforcing means embedded in the upper edges of the concrete section," and further whether such a combination constituted an original invention in view of the state of the art of reinforced-concrete construction in 1907.

The Patent Office examiner long opposed both of these contentions by the applicant's attorneys, and again and again rejected all the claims, citing numerous prior patents in support of their position. Not until very recently did the office finally recede from its position and grant the broad claims above referred to.

It is not, of course, our function to act as expert advisers to pass upon questions of the validity of patents. It is proper for us, however, to point out that in view of the long opposition of the Patent Office to the issuance of this patent, it is likely that the courts might take a similar view of it, should the threatened court proceedings for its infringement be carried into effect. Certainly the record of prior patents cited by the Patent Office, easily obtainable from the office files and very possibly prior use of steel reinforcement, not on the Patent Office records, should furnish plenty of ammunition for those who desire to fight such a suit rather than pay royalty.

Failure of Coffer-dam at Dam No. 1, Mississippi River St. Paul

Telegraphic reports from George W. Freeman, U. S. Assistant Engineer at St. Paul, state that on June 29 a portion of the mid-river coffer-dam used in building Dam No. 1 across the Mississippi River near St. Paul, Minn., was washed out under exceptionally high water for that time of the year.

Lock and Dam No. 1 are being built by the United States Government for combined power and navigation purposes. The work comprises the reconstruction of an old lock and the construction of a reinforced-concrete powerhouse and hollow reinforced-concrete dam across the river. The powerhouse and lock have been completed and a portion of the dam has been built within a coffer-dam. The river had then been turned through openings in the completed portions and the mid-river section of the dam was being built within another coffer-dam, comprising upper and lower barriers.

The flood crest is at last elevation [illegible] (Cairo datum), but this was designed for the high-water period, which ordinarily does not come at this time of the year. The coffer-dam had a top elevation of about 732. On June 4 the water rose to this elevation and flooded the dam. It [illegible] rising steadily until June 29, when an elevation of 734.4 was reached and water was flowing over the entire length of the coffer-dam. At 2:30 p.m., June 29, the [illegible] portion of coffer-dam between the [illegible] and the [illegible] failed, and in 15 minutes there was an 80-ft. gap. The lower barrier of the coffer-dam was washed away, but the [illegible] section of the upper barrier is intact. Three [illegible] of the partially completed reinforced-concrete dam (which was of a [illegible] cellular steel construction type) were undermined and are now in danger. These may be a total loss. There were several narrow escapes downstream from the dam, but no lives were lost.

Notes from Engineering Schools

University of Kansas—A correspondence course in water filtration and pumping will be given as state extension work. Prof. C. A. Haskins, as state sanitary engineer, found the men in charge of the water works of smaller cities inexperienced and without technical knowledge of the works.

Massachusetts Institute of Technology—Electrical engineering research has developed very rapidly during the past year and a noteworthy extension of the laboratory organization has recently been effected (aided by the cooperative agreement between Harvard University and the Institute of Technology whereby the two departments of electrical engineering were practically merged). There has been created a research committee to whom reports are made upon the progress of the various researches. The committee comprises (1) those members of the electrical engineering department staff who are supervising or actively engaged in research work, (2) those men who are personally carrying on research work in any branch of the department, and (3) those who have completed a recognized piece of research work during the preceding year. The research committee, as a whole, will meet once a month during the school term, such meetings being open to all members of the department staff. By this arrangement, the research activities of the department will be brought into close relation with the regular teaching work. Thus, any member of the staff, whether professor, instructor or assistant, who desires to carry out any original investigation may become identified with the research work through the research committee. Some of the special resources of the research laboratory which have not been designated for use in a particular investigation may be used in providing such a man with apparatus and other laboratory facilities. Even if a member of the department staff is not able to devote a considerable portion of his time to an experimental investigation, he will have the opportunity of offering suggestions upon the conduct of investigations which are being made by others.

The staff at present includes six research associates and assistants who give their whole time. This number will be increased to nine on July 1, 1914. In addition to the work of these men, who are appointed by the Institute, the theses of those students who are candidates for advanced degrees in electrical engineering have been carried on in the research laboratory during the past year. An amount of over $20,000 is available for salaries, supplies and other expenses in connection with the work of the research laboratory and library during the next year.

Massachusetts Institute of Technology—The Institute has accepted the recommendation of the Alumni Council in regard to the establishment of a new four-year undergraduate course—one in science, engineering

and business administration as outlined in ENGINEERING NEWS, Sept. 11, 1913, p. 578. This will be open in the regular program of the fall of 1914.

NEWS NOTES

A Private Water Tank Exploded during a fire in a residence in Walsenburg, Colo., on June 21. The tank was located in the attic.

An Earthquake in Southern Sumatra is reported to have caused widespread damage on June 26. Sumatra possesses a number of volcanoes. It is the largest island except Borneo of the Malay archipelago.

A Steamboat Damaged the Appoquinimink Bridge on her trip from Philadelphia, Penn., to Odessa, Del. The captain of the "Clio" is reported to have stated that he saw a white light on the bridge and supposed the draw span was open.

A Heavy Premature Quarry Blast, at the Melrose Granite Co.'s quarries, 3 mi. from St. Cloud, Minn., on June 23, killed one man and seriously injured three others. The four men were charging a "lift hole" 17 ft. in depth. The foreman was tamping the powder when the explosion occurred.

The S.S. "California" Went on the Rocks of Tory Island, Ireland, in a thick fog, on June 28. No lives were lost; the 1016 passengers of the "California" of the Anchor Line, bound for Glasgow, were landed at Londonderry on June 29. Two British destroyers early on June 29 stood by as long as needed.

A Lifeboat Broke Away from its Davits while loaded with passengers of the "Gothland," the Belgian steamship which was recently wrecked on the Scilly Islands, and fell 30 ft. into the sea. The bottom of the lifeboat was smashed, and all of the occupants were thrown into the water, but were rescued.

A House Slid Into an Adjoining Excavation for a moving-picture theatre in Brooklyn, N. Y., on June 23, seriously injuring two persons. While tearing down a cellar wall the adjoining house sagged, and the third floor and part of the second fell into the cellar. According to reports the house had not been shored.

A Steamer Was Wrecked on a Water-Works Intake Crib at the Chain of Rocks, St. Louis, Mo., on the night of June 24. It was claimed that rivermen were not notified of the construction of the crib, and further that the crib was equipped with lamps at the corners, only 4½ in. in diameter, visible only 200 yd. away. Divers found that the crib was uninjured, but that the "Majestic" had a hole in her hull, 30x3½ ft. It is probable that when the river lowers to a workable stage, the hole will be temporarily covered, the hull pumped out, and the vessel floated to Cairo for repairs.

Gas in a Deep Cesspool in East St. Louis on June 23, caused the death of the contractor who had built the cesspool, and of two other men. The contractor, discovering that a tool had been left at the bottom of the pit just completed in the rear of a grocery store, started down a ladder to recover it and was overcome by gases and fell into about 6 ft. of water. One after the other, two assistants who attempted to rescue him were overcome and fell. A fourth man was pulled back unconscious, before falling. The pit was 22 ft. deep by 18 ft. in circumference and connected to an old cesspool. It is supposed that the fumes came through the connecting pipe after the water in the old pit had run into the new. A lighted lantern is said to have been extinguished by the fumes.

The Salem Fire—At a little before 2 p.m., on June 25, a fire was discovered in a brick and wood factory building of the Korn Leather Co., in the leather and shoe district of Salem, Mass., which spread rapidly until an area of about 2 sq.mi. had been devastated. The damage is estimated at about $12,000,000. The original blaze moved eastward and westward with broadening front, before a brisk wind. First, a section of small frame residences and then the more important residential district in the western portion of Essex and Broad Sts., were destroyed.

Within an hour flying embers had started other blazes, in South Salem, and about 9 p.m., a third fire broke out, in North Salem, about 1½ mi. from the starting point of the original fire.

More than 1000 buildings, including a score of factories in the shoe and leather district, were destroyed and about 15,000 persons made homeless. The fire burned itself out on June 26. Seven persons are known to have died. Martial law was established at 9 p.m., June 25.

In addition to the Salem fire department, the neighboring cities and towns responded with fire apparatus and men; but the burning area was too great, the building construction too inflammable, and the water supply inadequate, to make resistance effective.

Structural conditions at Salem were as follows: Frame dwellings with out-buildings may be erected within the fire limits, but were restricted to 40 ft. in height and 2000 sq.ft. in area, if within 8 ft. of any other wood building. Frame tenements or lodging houses of over 30 ft. frontage must have a brick division wall. The height of frame tenements or lodging houses within the fire limits is restricted to 48 ft.

In the principal mercantile district about 75% of the construction is joisted brick, and the remainder frame. Heights vary from two to four stories.

The Pacific Great Eastern Ry. is rushing construction on its line between Vancouver and Fort George, B. C. The Squamish section is 93% completed, and track has been laid to within 20 mi. of the Pacific Coast terminal. Over 5500 men are now engaged on the construction work.

Brick Roads in Cuyahoga County, Ohio, will be increased 60 miles in length during the present season, according to the plans recently announced by the County Engineer. There are already about 400 miles of brick pavement in the county. A minimum width of 16 ft. has been adopted for the new roads. The present season's work will amount to about $900,000.

The Snake River Viaduct of the Oregon-Washington Ry. & Navigation Co., at Perry, Wash., is a steel structure 4500 ft. long, with its rail level 300 ft. above the water. The middle portion consists of five truss spans of 240 ft.; the remainder has 23 plate-girder spans of 60 ft. for the towers and 80 ft. for the intermediate spans. The bridge is expected to be completed this year.

Uniform Building Law for San Francisco Bay Cities—The mayor of Berkeley, Calif., has requested the coöperation of the executives of the cities surrounding San Francisco Bay in adopting a uniform building ordinance. At the present time there are many dissimilar clauses in the various ordinances, which prove a source of annoyance to engineers, architects and contractors whose practice is not confined to one city.

A Speed of 300 Miles an Hour has been claimed for a miniature electric railway system recently exhibited in England, and known as the Bachelet levitated flying train, the train being entirely unsupported during its travel. The inventor's modest claim has been easily outdone by another foreign inventor who claims that his system will give a speed of 500 miles per hour. The Bachelet inventor is pleasantly disposed of in the "Railway Engineer," of London, as follows:

> This interesting scientific toy is by no means new, as it was exhibited in the United States in 1912, but because the "experts" who write about such things in some of the daily and weekly papers had apparently never heard of it they thought they had seen a new wonder of the world, and became temporarily (we hope) demented, and gushed out the most dreadful nonsense about trains traveling at a speed of 300 miles an hour. The idea is that the car or container is raised off the track by magnetic repulsion and then sucked along by solenoids. The whole scheme, whether for parcels or passengers, is fantastic, and from a commercial and practical point is not worth a second thought.

Constructing a Filter Plant by Day Labor was one of the features of the new sewage-disposal plant at Aberdeen, S. D. (12,000 population), described by W. G. Potter in a paper read before the Western Society of Engineers. The plant includes a sedimentation tank, sludge filter, siphon chambers, sprinkling filter and final settling basin. The total cost will be about $130,000. Labor was paid 22¼c. per hour at first, but for most of the work the rate was 25c. per hour, and labor was very hard to get during the summer and fall seasons. Carpenters on form work were paid 35c. to 45c. per hour, and brick masons 70c. to 80c. per hour. The entire work except part of the excavation, part of the pipe hauling, and the construction of the pump-house superstructure, was done for the city commissioners by city forces, without contract, Mr. Potter being the designing and constructing engineer. He states that it is a good example of nonpolitical municipal work, and that politics was one of the incidental troubles that was entirely absent from this work.

The Plan to Sell the United States Battleships "Idaho" and "Mississippi," which was recently abandoned by the House and the Navy Department, was approved by the former body on June 23. The House reversed its former action and accepted in substance the Senate's amendment. The vote was 174 to 87, showing a remarkable change in sentiment. These

[illegible] to Greece for their value new, and the [illegible] in the purchase of a super-dreadnought.

Paving by Municipal Day Labor in Duluth, Minn., as noted in our issue of May 21, 1914, p. 1155, is proving very successful according to the Duluth Herald of June 15, which states:

[illegible] superintendent in charge of the paving of [illegible] St. between Fifteenth and Thirtieth Aves., is [illegible] a great deal of praise from merchants for the [illegible] which he is pushing the paving work. The business men say that not only is the city saving considerable money on the job by having the work done in this manner, but is also getting a better job done.

Highway Repair Work in Pennsylvania has received new [illegible] from a recent decision of the Dauphin County Court which releases $1,[illegible],[illegible], the accumulated money derived from automobile licenses, and places it at the disposal of the State Highway Department. Money for state road work has been scarce in Pennsylvania since the failure last fall of the proposed [illegible] bond issue to pass the referendum, and the highway engineering staff has been threatened with disintegration.

Coöperative Drainage Work is being carried out by the U. S. Department of Agriculture and the University of California. As a first experiment in the reclamation of land formerly highly productive under irrigation and covered with [illegible] vineyards, orchards and alfalfa, but now given up to alkaline barrens or Bermuda grass pasture, 160 acres of badly alkaline land at K[illegible] Park, near Fresno, will be [illegible]. This land belongs to the University of California. The field work for this investigation is in charge of Walter W. Weir, U. S. Drainage Engineer, Berkeley, Calif.

Motor Cars Have Displaced Steam Trains on the Central New York Southern Ry., a [illegible] line extending between [illegible] and Auburn, N. Y. The cars are of the gasoline type, [illegible] mounted on the [illegible] truck and driving the front axle direct for through [illegible] (or slow speed). They are [illegible] ft. long. The [illegible] end has a door for communication with trail cars. Other features are a [illegible] valve and whistle lever (pedal) at the rear [illegible] register which registers the mileage of each trip as well as the total mileage. They were built by the McKeen Motor Car Co., of Omaha, Neb.

The Coming Extension of Auto-bus Service is indicated by the fact that [illegible] applications for approval of auto-bus [illegible] were [illegible] for hearing before a member of the Public Service Commission, Second District, at Albany, N. Y., on June 24. The names of the applicants and the proposed routes were as follows: [illegible]

Cement Gun Operators Are Not Plasterers [illegible]

[illegible]

The Investigation of the "Empress of Ireland" Disaster [illegible]

afterward and the Court will have to sift out from the mass of conflicting testimony whose was the act that brought the two vessels into collision.

The very short time in which the "Empress of Ireland" remained afloat after her side had been pierced by the "Storstad's" bow is explained by the fact that the doors through the water-tight bulkheads were open when the collision occurred. There was no means by which they could all be closed simultaneously from the Captain's Bridge, and the steward whose duty it was to close the doors had no time to do so after the collision, although some doors were closed. There has been no thoroughly satisfactory explanation of the excessive list of the vessel as she sank. It is thought, however, that one of the boilers may have broken from the mountings by the collision and rolled to the side of the ship, and as the vessel listed more water would come in through open port holes.

A Neighborhood Center Planning Competition is to be held under the direction of the City Club of Chicago. The object is to show the desirability of and possibility of developing the city as a federation of neighborhoods, but not to the extent of isolation. While an enormous amount of trade is scattered through Chicago, local business suffers from the lack of district trading points and the local trading centers are not distributed according to any plan, but rather by [illegible] influences. This lack of definite arrangement applies also to such social institutions as schools, post offices, police and fire stations, playgrounds, libraries, social settlements, [illegible], etc. The city's population averages 12.2[illegible] per sq. mi., with 71,[illegible] and 3[illegible] as the maximum and minimum. For the residential area, the average is [illegible] and the maximum [illegible] per sq. mi. There are [illegible] of [illegible] to [illegible] in the outer sections, and about [illegible] of the whole area of the city is still vacant, while the residential districts represent about [illegible]. [illegible] competitors will reach their own conclusions as to what institutions to include in their plans, and the plans need not apply specially to Chicago. The preliminary competition will close Nov. 9, and a jury will select a number of the best plans, whose authors will enter a final competition closing Jan. 25. An exhibition of the plans will be held in February. Further information may be obtained from George E. Hooker, Civic Secretary, City Club, [illegible] Plymouth Court, Chicago.

Panama Canal Fender Chains. Three sections of fender chain, two of which were [illegible] ft. long, and one of which was [illegible] ft. long, all three making one complete chain [illegible] ft. in length, arrived on the Isthmus on June [illegible] on the steamship "[illegible]." [illegible] [illegible] Nos. [illegible] and [illegible] at Pedro Miguel Locks to protect the intermediate gate in the east [illegible]. With the delivery, [illegible] complete chains out of the [illegible] required have reached the Isthmus. [illegible]

[illegible]

New York Town Awarded Contract for Highway Construction. [illegible]

[illegible]

engineer's estimate had been kept at a particularly low figure so that it would not be likely that anyone would bid under the price bid by the town.

Section 131 provides that if such contract be awarded the board of supervisors or town board, such board shall by resolution designate some suitable person or persons to carry into effect on behalf of the town such contract and transact all business in respect thereto, as may be necessary. This action has been taken in the case of the Town of Mendon and bond has been given to the town guaranteeing the faithful performance of the contract. Under the provisions of the law, the board of supervisors and the town board will designate by resolution a banking corporation or a trust company wherein the moneys received on such contract will be deposited.

This system of building roads by the town has been tried in the past but has not been entirely successful; but it has never been demonstrated that the fault was with the system; on the contrary it was believed that it was entirely with the way the work was carried out.

Under a recent amendment of the Highway Law, any town can bid for a contract for state or county highway and if the contract is awarded, and it desires to do so, can make application to the Superintendent of Prisons for convict labor to work on the roads. In this case, the Town of Mendon is not going to do this but is going to do the work itself the same as any contractor would do.

PERSONALS

Mr. S. Hickson has been appointed Roadmaster of the Oregon-Washington R.R. & Navigation Co., at Colfax, Wash., succeeding Mr. T. Keaveny, resigned.

Mr. Charles J. Chenworth, Engineer of Roadway of the Atlantic Coast Line R.R., Savannah, Ga., has been appointed a member of the Board of Drainage Commissioners of Savannah.

Mr. C. M. Means, M. Am. Inst. E. E., Consulting Engineer, Randolph-Means Co., Pittsburgh, Penn., has been appointed Consulting Electrical Engineer of the United States Bureau of Mines.

Mr. N. P. Zech, recently in charge of statistics of the subsidiary companies of H. M. Byllesby & Co., Chicago, Ill., has been elected Comptroller of the Atlantic Gas & Electric Co., New York City.

Mr. Joseph S. Mallary has resigned as Fire Marshal of Philadelphia, Penn., to become Chief Engineer of the Merchant & Evans Co., of Philadelphia. He is succeeded as Fire Marshall by Mr. George W. Elliott, Deputy Fire Marshall.

Dr. Edgar Marburg, M. Am. Soc. C. E., Professor of civil engineering at the University of Pennsylvania, delivered the commencement address on June 11, and received the honorary degree of Doctor of Laws, at Franklin and Marshall College.

Prof. John H. Nelson, of the department of applied mechanics, Worcester Polytechnic Institute, has been granted six months' leave of absence, which he will spend as Associate Engineer-Physicist, United States Bureau of Standards, Washington, D. C.

Mr. George H. Wynn, of Canton, Ohio, has been appointed Resident Engineer in charge of construction of the new sewage-disposal plant at Canton. Mr. Wynn received the highest rating at the recent civil-service examinations. He was formerly with the engineering staffs of the American Bridge Co., Pittsburgh, Penn., and the Berger Co., of Canton.

Mr. William A. Williams, M. Am. Inst. M. E., recently Chief Geologist of the Associated Oil Co., San Francisco, Calif., has been appointed Chief Petroleum Engineer of the United States Bureau of Mines, San Francisco office. Mr. Williams is a graduate of Leland Stanford University, and has made a specialty of petroleum mining for the past 10 years.

Mr. J. H. Toupet has resigned as Chief Engineer of the National Fire Proofing Co., and has opened an office at 1428 Oliver Bldg., Pittsburgh, Penn., under the firm name of Toupet, Bell & Conley, Inc., Fireproofing Specialists and Contracting Engineers. Mr. Toupet is President, Mr. F. C. Bell, Treasurer and Mr. F. G. Conley, Secretary of the new firm.

Prof. R. L. Sackett, Assoc. M. Am. Soc. C. E., of Purdue University, Lafayette, Ind., has been appointed a member of a newly created State Highway Commission of Indiana. The other four commissioners appointed by the governor are Messrs. Thomas Taggart, of Indianapolis; W. H. O'Brien, of Lawrenceburg; Leonard B. Clore, of Laporte, and Addison C. Harris, of Indianapolis.

Mr. I. M. de Varona, M. Am. Soc. C. E., Chief Engineer of the Department of Water Supply, Gas and Elect 'city, New York City, has resigned. Mr. de Varona is 72 years old and has been in the city service for over 30 years. He will probably retire on a pension of half his salary of $10,000 per annum. Mr. de Varona graduated from Rensselaer Polytechnic Institute in 1863, and was first connected with the Brooklyn water-works as Assistant Engineer. Later he was Chief Engineer of the Brooklyn water-works.

Prof. Frederick G. Cottrell, M. Am. Inst. M. E., formerly of the University of California, Oakland, Calif., has been appointed Chief Chemist of the United States Bureau of Mines. Prof. Cottrell has been Chief Physical Chemist with the Bureau of Mines since 1911. He is a graduate of the Universities of California, Berlin and Leipsic, and is famous as the inventor of the process for electrical precipitation of suspended particles from smelter fumes, described in "Engineering News" of Oct. 26, 1911. In order to accept his position with the Bureau of Mines he gave to the Smithsonian Institution at Washington his patents on this and other valuable processes.

Mr. William McClellan, F. Am. Inst. E. E., Consulting Engineer, New York City, formerly Chief of the Division of Light, Heat and Power, Public Service Commission, Second District, New York, has been appointed "Confidental Engineer" in charge of the physical valuation and investigation of the New York Telephone Co. The chairman of the Public Service Commission is reported to have said that he would ask the commission to place all appointments to be made in connection with this work under the exempt class. Mr. McClellan was born in Philadelphia, Penn., in 1872, and graduated from the University of Pennsylvania in 1900. From 1905 to 1907 he was with Westinghouse, Church, Kerr & Co., New York City.

Dr. William David Coolidge, Assoc. Am. Inst. E. E., Assistant Director of the Research Laboratory, General Electric Co., Schenectady, N. Y., has been awarded the Rumford Medal of the American Academy of Arts and Sciences for his invention of ductile tungsten and its application in electric illumination. Dr. Coolidge was born in Hudson, Mass., and graduated at the Massachusetts Institute of Technology in 1896. He received his Doctor's degree at the University of Leipsic in 1899. Until 1905 he was a member of the faculty of the Institute. He was appointed Assistant Director of the Research Laboratory of the General Electric Co. in 1908. Some of the other recipients of the Rumford Medal have been Ericsson, Langley, Edison, Curtis and others.

Mr. W. Averill Harriman has been elected Vice-President of the Union Pacific Ry., to succeed Mr. W. V. S. Thorne, resigned. Mr. Harriman is 24 years old and has had no very extensive railway operating experience. He is, however, the son of the late Edward H. Harriman. Mr. Thorne is a graduate of Sheffield Scientific School, Yale University, and has been in railway work since January, 1886, when he joined the engineering staff of the St. Paul, Minneapolis & Manitoba Ry., on preliminary surveys and construction. He was subsequently promoted to be Superintendent of the Minnesota division of the Great Northern Ry., and was later an executive officer of other railways. He became connected with the Union Pacific Ry. in 1902 as Assistant to the President, E. H. Harriman, and has since been in charge of the purchasing department. Mr. Harriman is reported to have spent part of his summer vacations working as a chainman of a survey party, as a fireman on a locomotive and as a clerk in the freight department of the Union Pacific Ry.

OBITUARY

Russell S. Penniman, former General Manager of the West Coast Division of the E. I. du Pont de Nemours Powder Co., died June 18, at his home in San Francisco, Calif.

Newton Wilson, M. Am. Inst. M. E., of Beaumont, Tex., died in St. Louis, Mo., June 23. He was 56 years old and widely known throughout the Southwest and Mexico.

Edmund C. Limbach, M. Am. Inst. M. E., was accidentally killed in a mine at Oglesby, Calif., June 16. He was 42 years old and a graduate of the Colorado School of Mines, class of 1891.

Morgan Bransby Williams, M. Inst. C. E., in early life connected with the construction of some of the most important railways in England, died in London, June 22, aged 89 years. For the past 20 years he had been a banker of prominence. He was born in 1825. After a grammar-school education he started his career in mining engineering, but subsequently turned to civil engineering and railway construction. He was employed on the construction of the London & Northwestern Ry., the Caledonian Ry. and the London & Southwestern Ry. He then went to Italy, where he was Engineer of Construction on numerous railway lines, and later to Russia, where he was Chief Resident Engineer for the late Sir

[illegible] Hlwshlw. While in Russia he married the Baroness von Wulf, daughter of the Military Governor of St. Petersburg. For some time Mr. Williams was General Manager of the [illegible] & [illegible] Ry. in Russia, until it was purchased by the Russian Government. He then retired from engineering and railway work and made his home in South Wales.

Mrs. George Westinghouse died at her country residence, Erskine Park, Lenox, Mass., on June [illegible]. Mrs. Westinghouse had been in ill health since September, 1912, when she suffered partial paralysis. Since the death of Mr. Westinghouse, in March last, her condition has been serious. Mrs. Westinghouse was the daughter of Capt. Daniel Walker, of Roxbury, Delaware County, N. Y. She was married to Mr. Westinghouse in Brooklyn, N. Y., Aug. 8, 1867, when he was a young and comparatively unknown inventor. Mrs. Westinghouse was prominent in social matters and in charity work, and took a great interest in Mr. Westinghouse's engineering activities. When the American Society of Mechanical Engineers held its Washington meeting in May, 1898, Mrs. Westinghouse gave a special reception in her Washington residence to the Society, building a special pavilion on the lawn adjacent to the house in order to accommodate the large number of guests. In later years she had been present with Mr. Westinghouse at many of the Society's social affairs and had become well known to many of the members.

Benezette Williams, Consulting Engineer, of Chicago, died at Western Springs, Ill., June 22. His residence was at that place and he was about to start to attend the commencement exercises at the University of Michigan, where he was to receive an honorary degree of Master of Engineering. He fell dead in the railway station. He was born at West Liberty, Ohio, Nov. 9, 1844. He graduated from the University of Michigan in 1869, and the same year went to Chicago, where he entered the office of E. S. Chesbrough, civil engineer. Later he was in the office of the city engineer of Milwaukee, and then in railway service on the Milwaukee, Lake Shore & Western Ry. and Chicago, Burlington & Quincy R.R. In 1872 he became Assistant Engineer for Mr. Chesbrough, then City Engineer of Chicago; he worked in the sewer and water-works departments, was in charge of the construction of the [illegible] Ave. [illegible], and later became Superintendent of Sewers. He was City Engineer of Chicago from 1875 to 1879. He took a prominent part in the preliminary projects and the early construction of the Chicago drainage canal, and was Chief Engineer of the Sanitary District of Chicago (which is in charge of the canal) in 1892 and 1893. Afterward he took up private practice, maintaining an office in Chicago and making a specialty of municipal and sanitary engineering. He was a member of a commission appointed some years ago to report on an improved water-supply for St. Louis, Mo. He became a member of the Western Society of Engineers in 1872 and was president of the Society in 1880. He was married to Lydia J. Terrell at Cleveland, Ohio, in 1871, and had three sons and a daughter.

ENGINEERING SOCIETIES

COMING MEETINGS

AMERICAN SOCIETY FOR TESTING MATERIALS.
June 30-July 3. Seventeenth annual meeting at Atlantic City, N. J. Secy., Edgar Marburg, University of Pennsylvania, Philadelphia, Penn.

AMERICAN SOCIETY OF ENGINEERS, ARCHITECTS AND CONSTRUCTORS.
July [illegible]. Convention at [illegible] Beach, L. I. Secretary, T. [illegible], [illegible] St., New York City.

AMERICAN SOCIETY OF HEATING AND VENTILATING ENGINEERS.
July [illegible]. Semi-annual meeting at Cleveland, Ohio. Secy., J. J. [illegible], [illegible] St., New York City.

OHIO ELECTRIC LIGHT ASSOCIATION.
July [illegible]. Annual convention at Cedar Point, Ohio. Secy., [illegible], [illegible], Ohio.

AMERICAN ASSOCIATION OF RAILROAD SUPERINTENDENTS.
[illegible]. Annual meeting at New York City. Secy., E. H. [illegible], [illegible] Union Station, St. Louis, Mo.

AMERICAN PEAT SOCIETY.
[illegible]. Annual meeting at [illegible], [illegible]. Secy., Julius Bordollo, 17 Battery Place, New York City.

Inland Waterways Association—[illegible] to organize a section of the Inland Waterways Association in the Sacramento Valley, California.

Pittsburgh Chapter of the Illuminating Engineers' Society—At the annual meeting of the Chapter held at the [illegible] [illegible] [illegible] was elected Chairman and F. H. [illegible], Secretary.

Railway Signal Association—The next annual convention will be held Sept. 22-24, at Bluff Point, N. Y., with headquarters at the Hotel Champlain. The secretary is C. C. Rosenberg, Times Building, Bethlehem, Penn.

Illuminating Engineering Society—The eighth annual convention will be held Sept. 21-25 in Cleveland, Ohio. The assistant secretary is Joseph Langan, 29 West 39th St., New York City.

Fourth American Road Congress—The Congress under the auspices of the American Highway Association, and the American Automobile Association, will be held in Atlanta, Ga., Nov. 9-14. Inquiries should be addressed to Colorado Bldg., Washington, D. C.

Portland Association of Members of the American Society of Civil Engineers—At a regular meeting of the Association held in Portland on June 5, Frederick W. Mulkey, Chairman of the Commission of Public Docks, spoke on the Portland Harbor and Docks.

American Society of Agricultural Engineers—The next meeting of the Society, whose membership has grown 25% since Jan. 1, will be held in Chicago, Dec. 28-30. One of the items for discussion is whether to hold an extra meeting in San Francisco during the Panama-Pacific exposition. The secretary is F. M. White, Madison, Wis.

Southwestern Water-Works Association—At the annual convention held at Tulsa, Okla., June 15-17, the following officers were elected: President, H. L. McDuffie, Sherman, Okla.; Vice-Presidents, Jesse Shaw, Topeka, Kan., and W. H. Bruce, Fort Smith, Ark., R. E. McDonnell, Kansas City, Mo., L. H. Gray, Lufkin, Tex., and J. B. Hudgins, Roswell, N. M.; Secretary-Treasurer, E. L. Fulkerson, Waco, Tex. The 1915 convention will be held at Galveston, Tex.

National Association of Sheet-Metal Contractors—About 600 delegates attended the 10th annual convention of the Association, held in Cincinnati, Ohio, June 16-19. The next annual convention will be held in Denver, Colo. The officers elected for the ensuing year were: President, Paul F. Brandsted, Washington, D. C.; Vice-Presidents, Julius Gerock, St. Louis, Mo., K. I. Willis, Moline, Ill., and T. P. Walsh, of Youngstown, Ohio; Treasurer, W. A. Fingles, Baltimore, Md.; Secretary, Edwin L. Seabrook, Philadelphia, Penn.

Sixth International Congress of the Mining, Metallurgy, Engineering and Economic Geology—The Sixth Congress will be held in London, July 12-17, 1915, and will be divided into four sections: Mining, metallurgy, engineering and economic geology. Among the subjects to be treated in the engineering section are the following: Exhaust-steam turbines; gas motors and turbines; compressed-air locomotives in mines; economies of rock drilling; standards of comparison in the use of compressed air; utilization of low-grade fuel. Inquiries should be addressed to the Secretary of the International Congress, 28 Pretoria St., London, S. W.

The Pacific Northwest Society of Engineers—The 12th annual convention of the Society was held in Seattle June 19-20. President Joseph Jacobs, in his annual address, made a plea for the opening up of the arid and logged-off lands of the Pacific Northwest. In speaking of the opening of the Panama Canal, he said: "Of the 300,000 to 600,000 immigrants likely to come to the Pacific Coast, Washington will get at least 10,000, and if only five acres per capita were allowed, it would total 200,000 acres; figuring $50 per acre as cost of reclamation, the expenditure would be $10,000,000." In the afternoon session a paper was delivered by Floyd W. Allen, Deputy Engineer of King County, on "Highway Construction." In the evening the annual banquet was held at the Hotel Frye. Sterling B. Hill acted as toastmaster, and the principal address of the evening was delivered by D. C. Henny, Consulting Engineer of the United States Reclamation Service, who spoke on "Drainage Problems in the Yakima Valley."

New England Water Works Association—The June outing of the association, held in Worcester, Mass., June 24, was a very enjoyable affair. After the arrival of the main party from Boston at 9:15 a.m., automobiles and a special trolley car were taken to the town of Holden, where the new reservoirs of the Worcester water supply were inspected. At Pine Hill the city has begun the construction of a 68-ft. masonry dam on one of the most remarkable dam sites in the Eastern States. The valley is narrow, with a granite ridge running past with [illegible]. From Pine Hill the party proceeded to the Tatnuck Canoe Club House on an island in Lake Quinsigamond, where a lunch was served. Mayor Wright, of Worcester, was an invited guest. In the afternoon the party went to the northern outskirts of the city to witness the operation of a municipally owned Austin trenching machine. Afterward an inspection was made of the city water works shops and stable.

Engineering News

VOLUME 72 JULY 9, 1914 NUMBER 2

Making Three 24-in. Connection Cuts in a 60-in. Steel Water Main under Pressure, Pittsburgh, Penn.

By Chas. A. Finley*

It rarely happens that it becomes necessary to connect two 60-in. steel water mains, and at the same time keep the pressure in one of them. This was the problem encountered by the Bureau of Water of Pittsburgh, Penn., in March, 1914, and successfully solved by making three 24-in. cuts in the old main while under pressure and connecting as many branch pipes of that size with a three-way special provided at the end of the new main. The circumstances which led to this job and the details of design and execution are stated in the following text, which is supplemented by a plan and section and two halftone views of the connection.

Prior to the latter part of April of this year, the North Side of Pittsburgh (formerly Allegheny) had never enjoyed the advantages of filtered water. Up to that time it had been supplied with raw water by a 60-in. steel rising main from the Montrose Pumping Station, situated on the right bank of the Allegheny River, some miles above the city limits.

Going back a few years, it may be noted that after the consolidation of Allegheny with Pittsburgh, in 1907, measures were taken to remedy this condition. These measures necessitated the expenditure of $2,500,000, and embraced the erection of a new pumping station near the Pittsburgh Filtration Plant at Aspinwall, for supplying filtered water to Allegheny, the laying of some 1200 ft. of 60-in. riveted steel pipe connecting the Aspinwall Station with the 60-in. force main from Montrose at a point near the western confines of the Filtration Plant and, in an air line, 1050 ft. northwest of the Aspinwall pumping station, and the construction of a new storage reservoir.

Fig. 1. Making the Second 24-In. Cut in 60-In. Steel Water Main under Pressure, Pittsburgh, Penn., Looking North

(Three-way special in foreground; Smith tapping machine in right middle ground central connection already made, third connection, on left, not yet started.)

*Superintendent, Bureau of Water, Pittsburgh, Penn.

Owing to the available storage on the North Side being insufficient to permit throwing the Montrose force main out of service long enough to connect the two mains by a Y-branch, recourse was had to three 24-in. cuts in the Montrose main, all made under pressure and connected to the new Aspinwall main by means of a special three-way casting. (See the plan and section, Fig. 2, and the views, Figs. 1 and 3.) Each of the 60-in. mains is riveted steel, ½ in. thick.

Prior to the cuts being made the pipe was uncovered and inclosed in a reinforced-concrete vault, 11½x31½ ft. in plan. The roof and south wall were left off until after the pipe cuts were made. Concrete supporting piers and backing blocks at the point of each cut insured stability during the cutting operations.

The main was next encircled by three heavy cast-steel sleeves 4 ft. wide and 11 ft. 8 in. c. to c. Each sleeve was in two sections, provided with flanges held in place by twelve 1¾-in. nickel-steel bolts at each joint and made tight by means of lead gaskets ⅛ in. in thickness.

Owing to the flexibility of steel pipe and the possibility that the section in question might lend itself readily to distortion during calking some apprehension was entertained as to the possibility of obtaining satisfactory lead joints and in consequence special care was exercised to insure as equal a fit as possible between the pipe and the sleeves. The sleeves were poured solid throughout, [illegible] lb. of lead being required for each. All joints were painstakingly calked by experts, special attention being given to the area immediately surrounding the point of cut.

Flanged openings were provided on each sleeve to which were bolted 24-in. gate valves. Valves and openings were slightly in excess of 24 in. in order to allow for the cutting of a disk full 24 in. in diameter.

The valve being opened the cutter was inserted against the pipe and held in place by a cutting back, bolted to the valve through a stuffing-box from which the stem and gears protruded for operation. A 1½-in. drill preceded the main cutting tool a sufficient distance to penetrate the pipe before the 24-in. cutter was engaged, allowing the full pressure on the sleeve and gate and permitting of any additional calking found necessary before proceeding further. No particular difficulty was experienced in this respect, however, but had occasion demanded, the machine was equipped to tap and plug the 1½-in. hole, permitting the removal of the valve and sleeve without danger. Some minor leaks developed but were readily made tight and the cuts expeditiously completed.

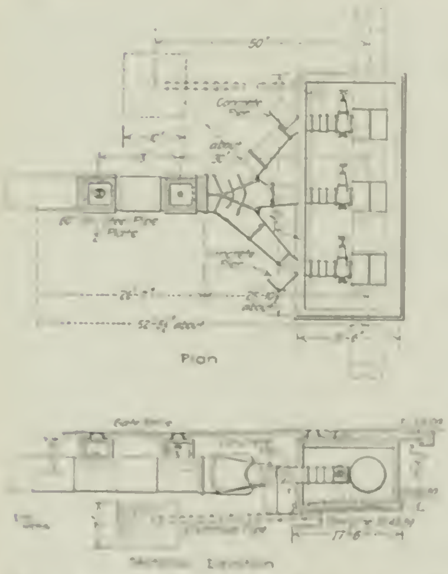


FIG. 2. PLAN AND SECTIONAL ELEVATION OF CONNECTION BETWEEN TWO 60-IN. STEEL WATER MAINS, PITTSBURGH, PENN.

FIG. 3. CONNECTING 60-IN. STEEL WATER MAINS AT PITTSBURGH, WITH MAIN UNDER PRESSURE; LOOKING SOUTHWEST

(Note flanged and bolted sleeves for use in tapping in the three 24-in. connections.)

The cutting machine was operated by hand. An average of five hours was required from the beginning to the completion of each cut, including the removal of the piece cut out.

The method employed to hold the cutting machine rigidly in place during the operation is shown by the views (Figs. 3 and 1), the extra heavy pipe being in compression and the rods passing through them in tension. After completion of the cuts and the installation of the 24-in. makeups, consisting of two flange and spigot pieces and a leaded sleeve between each valve and the three-way casting, these members were removed.

The cutting machine and castings were furnished and the cuts made by the A. P. Smith Manufacturing Co., of East Orange, N. J., under the direction of the Bureau of Water, Mechanical Division, of which C. O. Daugherty is Division Superintendent. F. W. Lyon, Division Engineer, was in immediate supervision of the work and T. R. Tarn, Division Engineer, was in charge of design.

Track Plans for Stations on Single-Track Railways

By G. P. De Wolf*

Among the important features in the design of the track layout at stations on single-track lines are the facilities for handling local freight traffic without obstructing through trains. In my 27 years of railway work (which have been pretty well distributed between construction and maintenance-of-way, with some experience in conducting transportation), I have given considerable study to conveniences for getting trains over the road, but it has been my observation that little attention has been given to this subject and that few roads appreciate the saving that can be made by a little care in the arrangement of tracks and conveniences at small stations.

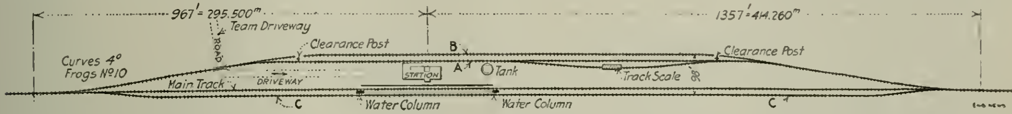
The item of overtime for train crews, together with additional fuel consumed and delay to equipment and freight, is a serious matter with single-track roads. Too much time is consumed by local freight trains at stations, and such a train occupying the main line at stations is frequently the cause of delay to through freight trains which otherwise would not stop, and through freights thus standing do not increase net earnings. The restarting of a train costs money and time, and when a train once stops, all the men have to get ready before it starts again; some crews are quick, while others are slow. The only way to get trains over the road is to keep them moving; main lines are built to run on, and (as far as practicable) should be used for no other purpose.

The accompanying plan represents the layout for local stations as adopted by the National Railways of Mexico, with the above object in view. It is designed with two main features: (1) to keep the main track clear of local freight trains while doing their work, in order to avoid delays to other trains; (2) to furnish a track to be used for local cars only, in order that they will be disturbed as little as possible and avoid interference with the work of shippers or consignees in loading or unloading these cars. Other features are arranged to conform with these two requirements.

Track *A* is the house track; *B* is the team track, and *C* is the passing track. The station has a combination freight and passenger building. At one end is the freight warehouse, with platform on two sides. The platforms are level with the floor of cars standing on the house track *A*; the height of floor of warehouse is just enough higher than edge of platform to give drainage. At the other end is the passenger waiting room, with the station agent and telegraph office between this room and the freight room.

For water stations, the tank is placed as shown, so that engines on track *A* can take water direct from the tank; water columns or engine standpipes are placed between the main track and the passing track *C*; and engines can take water from either track. These water columns are 50 meters (164.04 ft.) in each direction from the telegraph office. Passenger trains can take water while discharging and taking on passengers, express and mail. The scale track is put in only when needed. The freight warehouse is located at the end of station next to direction of business.

Track *A* is built in all cases; track *B*, where there are two freight trains daily in each direction, and track *C* where there are five freight trains daily in each direction. All cars left at station are placed on track *B*, leaving tracks *A* and *B* clear. The length of tracks *A* and *C* will be fixed to suit the traffic. The total length of layout as shown is 700 m. (2369 ft.) between main-line switches, but this is varied by the engineer according to the requirements of each station.



Standard Track Layout for Stations on Single-Track Lines, National Railways of Mexico

Local freight trains are required to head through track *A*, and not use the main track between the main-line switches, unless meeting another local freight. The train spots the local cars at warehouse; the conductor and swing brakeman handle local freight, while the head brakeman with the engine sets out and picks up cars to be left or taken. Generally both parties will finish about the same time, without having blocked the main line, except in entering and leaving the station.

*Chief Engineer of Construction, National Railways of Mexico, Mexico, D. F., Mexico.

The Standard Asphalt Pavement of Oakland, Calif., consists of a concrete foundation 6 in. deep, having a 1½-in. asphalt wearing surface laid on a 2-in. binder course of asphaltic concrete. This pavement will sustain the heaviest loads, even bridging over soft spots in the ground, can be torn up for pipes and replaced without damage, and its surface can be restored where worn at a minimum expense for patching. The only objection to this pavement is its slipperyness during a fog or light rain, but this difficulty has been largely eliminated throughout the hand-swept district by placing dry sand in suitable receptacles, to be applied by the street sweepers as needed.—Recent Report of the Commissioner of Public Works.

Investigation of a Break in a 36-In. Force Main, Toronto—Early last March a 36-in. force main connected with the water-works of Toronto, Ont., burst at Devonshire Place, near Bloor St. Apparently little damage was done except to the pipe and the street. We have received from R. C. Harris Commissioner of Works of Toronto, the following summary of results of investigation of the break:

Our investigations were carried out under these three main heads: (1) defective material; (2) water hammer, and (3) cooling strains.

Samples of iron from each of the broken pipes were analyzed, and its composition was found to be satisfactory. Bars cut from the broken pipes, and tested, gave good results. It would, therefore, appear that the breaks were not due to defective material.

Pressure-recording gages were placed at intervals along the mains, and vibration caused by the electric pumps was shown, but no abnormal pressure was registered, such as might cause the fracture of the pipe. Water hammer might have caused an excessive pressure, which would be transferred along the pipe so rapidly as not to be registered upon the gage, but since both of the breaks occurred during peak load intervals, and also as reliefs occur at two cross-connections, it is improbable that the breaks were caused by water hammer.

There remains the possibility that the breaks were due to cooling strain, and this assumption is strengthened by the fact that both breaks occurred in cold weather, and where the ground is somewhat easily penetrated by frost

Street Cleaning Methods and Costs at Washington, D. C.

By J. W. Paxton*

SYNOPSIS—In a paper† read before the Sanitary Engineering Section of the American Public Health Association at its Colorado Springs meeting, September, 1913, Mr. Paxton described how an efficient municipal day-labor organization had greatly reduced the cost of street cleaning as formerly done by contract in the city of Washington. Since then, he has received many inquiries as to the exact methods employed to attain these results. In this article are explained the cost-keeping methods for fieldwork, shopwork and stables. Many blank forms and cards are not reproduced, as these would probably vary according to the taste and experience of those who would be likely to make use of them, and because many changes in detail have been made since the system was established and many more are likely to be made before it is perfected. It should be remembered, too, as Mr. Paxton says, that the Washington system as a whole will probably fit no other street-cleaning department, the principles only are important.

One of the first attempts of the new municipal street-cleaning organization, under the Engineer Department, was to establish a cost-keeping system. As not much time was available for preliminary study, a rough system was started and enlarged upon from time to time. This period of development at an end, the other stage, that of [illegible], began.

As part of the preliminary study, reports and data from other cities were examined to see what had been done in street cleaning and cost keeping, but no system was found applicable to local conditions. Many valuable data were obtained, however, from the recent publications of well known cost-keeping and scientific-management experts.

The main appropriation of the Street Cleaning Division is for Dust Prevention, Cleaning and Snow Removal, which gives authority to hire laborers, mechanics, etc., but excludes foremen, clerks and superintendents, a separate appropriation, entitled Annual Salaries, being provided for these officials. The last appropriation, under the contract system, paid for inspection and superintendence, and except for minor changes was the same as the present [illegible].

Comparison of Day-Labor and Contract Costs—Neglecting for the present the items of interest and depreciation, which are thought to be high in contract work and, as will be shown later, are low or nonexistent when the work is done directly by the municipality, the contract price (see [illegible]) was composed of the contractor's expenses, the salaries of his supervisory force and his profit. The cost to the city was this price added to the expense of city supervision (inspection, measurement of work done and accounting), or:

(1) Cost to City = Contract price + City Supervision.

With municipal operation, charges corresponding to the contractor's direct expenses and his supervisory or overhead force must be incurred, but no profit need be figured, nor a second supervisory force maintained. Therefore, for municipal operation,

(2) Cost to City = Direct Expenses + Overhead Charges.

If we now suppose that an equal amount be expended under both systems, we have

(3) Contract Price + City Supervision = Direct Expenses + Overhead Charges.

Conditions in Washington, however, make this overhead charge under municipal operations equal to the city supervision expenses under contract. Canceling, then, these similar items, we have

(4) Contract Price = Direct Expenses.

Contract price, therefore, compared with the direct charges for labor, stable expense, supplies and repairs under municipal operation, gives the saving or additional cost to this city of the day-labor over the contract method of street cleaning.

Object of Cost-Keeping Methods—The object of the cost-keeping system being partly to obtain this comparison, the regular monthly cost sheets of the department include only the direct charges mentioned above. The main advantage of excluding all overhead expenses from these sheets is, however, the ease of comparison between similar gangs or classes of work as well as individual items. Overhead expense is added annually as a direct or *pro rata* charge, giving a second set of unit costs which can be used in comparison with unit costs in other cities where this item is included.

Depreciation and interest on investment, as charges against appropriations, are nonexistent. Extraordinary expenditures, such as the remodeling or the purchase of a stable, are provided for by special appropriations. Live stock is secured mainly from other departments, principally the fire and police. Transfers between departments of live stock and other equipment are made without charge. On the General Equipment Account, these transfers are recorded at the full purchase price, but no financial transaction is made. If any equipment or live stock is sold, the proceeds are returned to the United States Treasury and not credited to the appropriation available for current work. Very few sales of equipment take place for this reason; extensive repairs are made, practically offsetting all depreciation.

To admit of comparison, however, with contract costs or unit costs in other cities where it is desired to consider depreciation and interest, a theoretical charge at [illegible] of the total investment for interest and 1% of this total for [illegible] depreciation is made; 1% of the total investment being about [illegible] of the value of the live stock, giving a third set of unit costs.

As it is desirable for the cost keeping to check with the accounting, and it is necessary to conform to certain requirements of the auditing, purchasing and disbursing officers, which originated before this cost-keeping system

*Superintendent of Street Cleaning, Washington, D. C.
†Abstracted in "Engineering News," Oct. [illegible], 1913, p. [illegible].

was attempted, it is more complicated than a simple division of expenditures to obtain unit costs would be.

Expenditure Chart—Practically the first step was the development of a skeleton diagram showing from what appropriation and under what heads money was expended. The Expenditure Chart (Fig. 1) shows this diagram in its present state and gives the headings under which money is acquired and expended, and how these expenditures finally are included into the three sets of costs, which, when divided by quantities of work done, give the unit cost.

While a portion of the Annual Salaries and Contingent and Miscellaneous are joined up with the Streets appropriation, they reappear only as a Miscellaneous, and the line of this entry joins to Overhead and only enters the cleaning costs, such as Hand Patrol, Alley, etc., in the second set. Thus the first set of costs deals only with the Street appropriation.

Purchasing and Stores

All purchases must be made through the Purchasing Officer of the District of Columbia. The different departments notify him of their needs through requisitions, and he attends to the details of the purchase.

Supplies have been divided into two general classes, those purchased as needed on the open market, and certain standard articles contracted for annually, this latter class covering practically all articles regularly used.

Requisition Blanks—Under the cost system, material needed at the storeroom is requisitioned for on two forms, which are merely statements carrying a contract requisition number, the amount, article, item number, unit price, cost, contractor, directions for delivery, purpose; each requisition has an order number, is dated and signed by the foreman and approved by the Superintendent. These forms are purely local and are sent to the general street-cleaning office in duplicate, where, after approval by the Superintendent, the requisitions on the Purchasing Officer are made out. The form for noncontract purchases is printed on green paper, this distinction being advantageous as bids must be obtained, and considerably more time elapses between order and delivery, than is necessary with contract material.

Views in Storeroom, Municipal Street Cleaning Department, Washington, D. C.
[(1) View of general storeroom; (2) oil and paint room; (3) bolt rack in general storeroom; (4) lumber, iron and bulk storeroom.]

Upon receipt of the official order number from the Purchasing Officer, the local requisitions are given the same number, the duplicate is returned to the issuing storeroom, and the original is filed.

Material Received Slips—When material is received at the storeroom, a statement, giving order number, amount, unit price, date received and account charged to, is sent to the main office. This form is compared with the original requisition on file, for check on the delivery, and no voucher is approved until the requisition is satisfied.

Inventory Cards—Previous to July 1, 1911, stores were carried only for the hand patrol work, and repairs were made only on the few wagons used in that service. Consequently, for the new work, the storeroom and the

storeroom-accounting system became entirely inadequate. The first work in establishing the cost system was, therefore, in the storeroom. The floor space and shelving were more than doubled, a complete inventory was taken, the results being recorded on cards $7\frac{1}{4}$x$9\frac{1}{4}$ in., designed to fit a filing drawer $9\frac{1}{2}$ in. wide. One such card is made out for each kind of a supply in the storeroom, contract material being on yellow cards while noncon-

proper date in the Received column, and the On Hand column increased by the amount received.

Order Slips—Issues from the storeroom are made on a Storeroom Order Slip, showing to what the articles listed should be charged. This slip is also used for recording credits, the In column being for this purpose. After issuing or receiving supplies on the order slip, the articles listed are entered in the Issued or Received

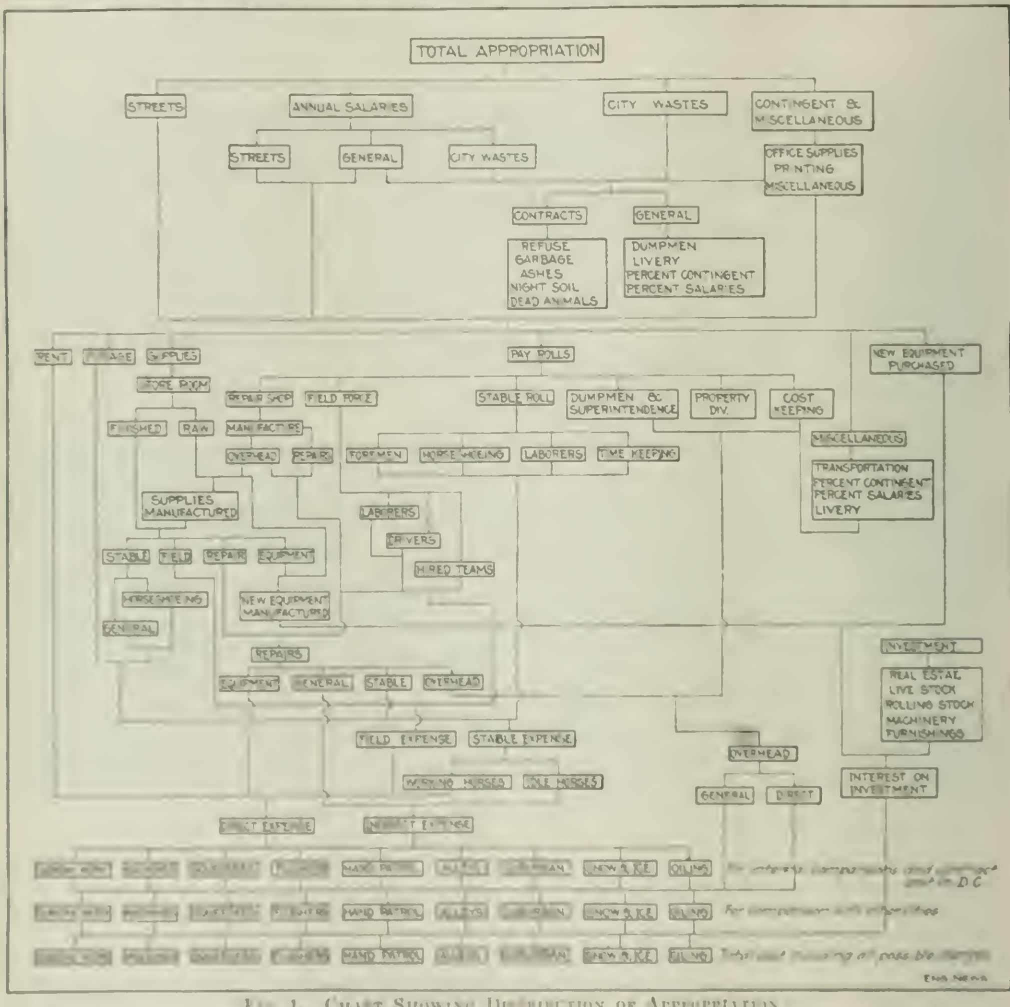


Fig. 1. Chart Showing Distribution of Appropriation

([illegible] such expenditures as are considered in obtaining [illegible])

[illegible] and manufactured material is recorded on [illegible] colored cards.

Requisitions are made up from the information given on the Stores Cards, and are recorded as to date and quantity under the heading "Material Ordered," the [illegible] order number being filled in upon the return of the duplicate requisition from the general office. [illegible] of material purchased, the order number and quantity are entered opposite the

[illegible] of the Stores Card, and the amounts are deducted or added to the quantity on hand.

Stock System—This Stores Card ledger consists of about 2000 cards and about half the time of one clerk is required to post entries, make out requisitions, etc. The value of stock averages about $20,000.

At first, inventories were taken every six months, but the error found was so small that, at present, material on hand is only counted when a new supply is ordered.

With each requisition is forwarded an account showing for each article the amount actually on hand and the amount called for on its Stores Card. This record is of value, not only as a check, but particularly as a guide to the Superintendent in going over the requisitions submitted for his approval.

Among the advantages of some such a stores system are a perpetual inventory of stock on hand, with all articles located, priced, and automatically replenished by maximum limits, which prevents overstocking, and by minimum limits, which prevents running short. Stock is issued only on written order, and all losses eliminated.

Time-Keeping

The appropriations for street cleaning divide the employees into two classes, those paid a yearly salary, the titles and amounts of which are specifically fixed; and those paid per diem.

The duties of the annual employees, which include all the foremen, clerks and higher officials, are not subject to sudden or frequent change, and so far as the cost-keeping is concerned, their time is added yearly as an overhead charge.

Semi-Monthly Time Reports—The time of all per diem employees is reported on the semi-monthly Time Report, consisting of a permanently bound page (*a*), printed and ruled with a column for name, rate of pay, and columns for each day, numbered above from 1 to 7 inclusive, and below from 16 to 22 inclusive, like the left-hand main sheet (*c*); a perforated transparent sheet (*b*), with heading, name and rate columns as on the left-hand page (*c*); the double-page main sheet (*c*), which is bound on a perforated stub; and a page (*d*), printed and ruled as the right-hand main page (*c*), which is a continuation of the left-hand side with the columns for days numbered to 15 and 23 to 31, and there are three extra columns for total hours and days and amount of pay due. Between (*a*) and (*b*) a double-faced carbon sheet is bound, duplicating any mark on the left page of (*c*) on both (*a*) and (*b*). For duplicating on (*d*), characters written on the right-hand page of (*c*), a single-faced carbon is bound between.

On the 13th and 28th of each month, the perforated, transparent sheet (*b*) is torn out and sent to the office, where it is used in entering names and rates on the payrolls, which are then forwarded to the Disbursing officer who transfers this information to the pay envelopes. At the end of the semi-monthly period, the main sheet (two facing pages) (*c*) is separated from its perforated stub. The removal of the carbon sheets leaves the foreman sheets (*a*) and (*b*), which are exact copies of each half of (*c*).

Upon receipt of the main sheet (*c*) in the office, the hours are added, reduced to working days of 8 hr. each. and the amounts due determined. These amounts are then entered on the payroll; and the timebook sheets (*c*), the original record, are bound and filed as the permanent office record. As indicated above, the foreman is also enabled to retain a carbon copy of the original record. This method of time-keeping, as compared with the old method, has eliminated several duplications with the consequent probability of mistakes. Disputes between foremen and office are avoided; clerical work in the field and office is saved and it is possible to pay off one day earlier.

Shop Methods and Accounts

The shops of the Street Cleaning Division comprise a wood-working shop, blacksmithy, paint shop, tin shop, harness and leather shop, broom-making shop, and a general repair shop. Modern power-driven tools, such as an engine lathe, boring machines, power hammer, band saw and planer have been installed, and all repair work is done at the department's shops. In addition, carts, wagons, etc., are built, and such supplies as hand- and machine-brooms, pan scrapers, waste-paper cans, etc., are manufactured.

The greater part of the repair work is on the rolling stock, which is numbered consecutively, carts being 1 to 50, wagons 50 to 75, etc. As the same equipment is always sent out to each gang, and the repairs to each piece of apparatus are recorded on separate cards, these numbers also serve the purpose of job numbers.

Jobs other than repairs to rolling stock are given a key letter and numbered consecutively; all jobs which, when finished, are turned in to the storeroom, have the letter "A" followed by a number, and ordinary jobs have "B," with a number.

Work Orders—The storeroom Order Slip, previously described, when filled out by the shop foreman, is also used as a work order. Each shop is provided with a small rack of four compartments for holding duplicates of these work orders, the first compartment for a job under way, the second for that to be next taken up, the third for future jobs, and the fourth for finished work. The original work orders are filed in a similar manner in the storeroom which is connected to the shop office.

Shop Methods—When a job is finished, the workman removes the slip from the first compartment of his rack, signs, dates and places it in the compartment for finished work. The slip in the second compartment is then moved to the first, the first of those in the third compartment moved into the second, and work commenced on the new job.

Slips are collected frequently from the Finished Work-boxes and turned into the storekeeper, who immediately rearranges his rack to correspond to those in the shops, calling in any material remaining from the old job and issuing that called for on the new order slip.

If additional material is found necessary as a job progresses, the storekeeper adds it to the slip in his rack. Each day the foreman looks over the active slips of this rack and sees that none but proper material and in proper amount has been issued.

After crediting any material remaining from a job, the original and duplicate order slips are fastened together, the material charged off the Stores Cards, and the slips are then sent to the main office for posting on the cost records.

Paint and Harness Shops—In the case of paint and harness shops, it has been found necessary to vary the normal shop procedure. It is impossible to issue and return leather and paint after each job without driving the system to extremes. Leather and paints are accordingly issued in small quantities, these being charged on an Order Slip as a supply to the shop. When turning in work orders, the amount and kind of paint, or leather,

used is estimated by the workman. In the main office, a perpetual inventory is kept, and checked at the end of each month, by an actual inventory of material on hand in the paint and harness shops.

General conditions are such that a bonus or even piecework system is impossible; but for manufactured articles, a standard has been set and a certain quantity and quality demanded.

Time Slips—The Time Slip records give the time of

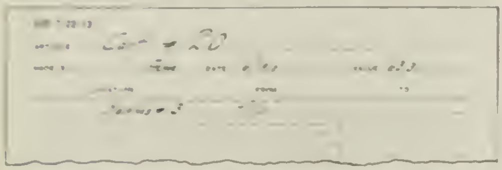

Fig. 2. Front Face of Equipment Card; Actual Size, $7\frac{3}{4}$x$4\frac{3}{4}$ In.

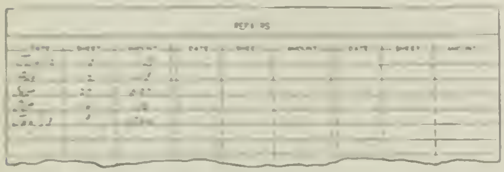

Fig. 3. Reverse Side of Equipment Card

the shop employees. Each man is listed on a separate slip headed with his name, number, and rate of pay per day. The slips are kept by the shop foreman, the job number being placed opposite the time of starting. At the close of the day, the time and amount chargeable to each job is calculated, and the total hours recorded are posted to the man's credit on the Semi-monthly Time Report, previously described.

When the Time Slips are received at the main office, the overhead charge on each job is determined and entered in red ink at the right of the Amount column. This overhead charge is the expense of per diem foremen, storekeepers, timekeepers, etc., at the repair shop and is charged as a percentage of the direct labor cost.

Repairs and Manufactures—As the work of the shops can be divided into two general classes—Repairs and Manufactures—two corresponding office records are compiled. The monthly Repair Sheet, with column headings, material, date, time, total charge to, is used for all repair work whether on rolling stock or "B" jobs; and the Manufactures Sheet, with column headings, date, material used, time, remarks, is used for new equipment or new improvements—all "A" jobs.

The Repair Sheets are made up from the Storeroom Order Slips and the Time Slips. For convenience, the Repair Sheets are grouped as far as possible, all cart repairs being placed on one sheet or set of sheets, wagon repairs on a second set, "B" jobs on a third, etc.

Equipment Records—Repairs charged on these sheets are transferred to Equipment Cards (Fig. 2), one such card being made out for every individual piece of apparatus owned by the department. The face of these cards record the manufacturer, date and value, as well as its present location, thus forming a convenient equipment account. The reverse side contains a record of the cost of repairs, the Repair Sheet numbers, locating the details of each job for reference. This record of repairs is valuable in comparing the relative efficiency of similar kinds of apparatus.

Record of Manufactures—The Manufactures Sheet is made up similar to the Repair Sheet, the quantity manufactured being credited on Storeroom Order Slips. At the end of each month, these sheets are totaled, incomplete jobs are transferred to the new sheets, and in the case of brooms or other supplies made up in quantities, an average cost is obtained for the month. This is again divided into the average unit cost of each component of the manufactured article, and the information is recorded on the Manufactures Index cards, 5x8 in., giving a comparative unit cost record, showing increases or reductions from previous months.

Materials Record—The Material Sheet gives a record of finished supplies received or returned by foremen, stable losses, etc., the information being obtained from Storeroom Order Slips. A check on the Material Sheet is obtained from the Foreman's Inventory, which is a printed list of all ordinary tools and supplies with column headings to be filled in, on hand, received, sent to storeroom, lost or stolen, remarks. The material on hand in the toolhouses or lockers is also given.

The Supply Summary, 5x8-in. card, collects and condenses the information of the Material Sheet and Fore-

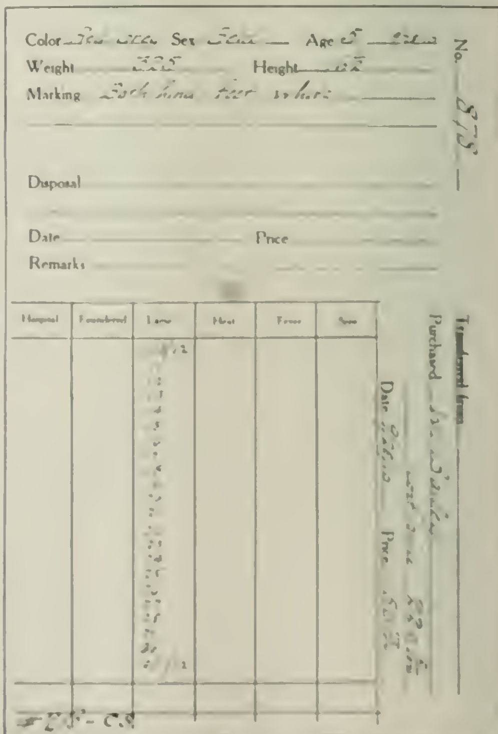

Fig. 4. Horse Identification Card; Actual Size, 6x4 In.

man's Inventory in an account which shows immediately any abnormal issues to the foremen or change in the stock carried in the toolhouses or lockers. It also gives a comparative record of supplies issued to or carried by different foremen.

Stables

Horses are obtained by purchase or through transfers from other departments. Every horse is given a description and a number by the district veterinarian. Upon entering the street-cleaning service, this information is recorded on a blue card (Fig. 4), 4x6 in. A disability record is posted from the daily reports of the stable foremen, which shows the assignments of the various horses and is useful in deciding when horses are not rendering efficient service. Upon condemnation, the data and method of final disposition are also entered.

A distribution of the number of horses for each division of the work, under normal conditions, is authorized by the Superintendent. This is entered on the same sheet as the Stable Profile, each time a change is made, in the form of a table, giving also an equipment and labor distribution.

Stable Profiles—The Stable Profiles (Fig. 5) show graphically, on standard profile paper, information obtained from daily reports of the stable foremen, such as the number of horses in the stables, sick, convalescent, available for work, and working. The line of normal distribution given in the tables is also plotted on the same scale. Three separate profiles are kept, one for each stable, and a combination one for the entire division.

Distribution of Stable Costs—For cost-keeping purposes, a monthly Horse Distribution Sheet is arranged from the normal distribution tables which accompany the Stable Profiles, and the daily Horse Distribution Report. If, on account of bad weather, Sundays, lack of drivers, etc., the regular quota of horses has not been worked, their expenses are still charged, as maintenance goes on just the same. In addition, any extra horses which have been used by any division of the work are charged directly. The total expense of the remaining extra horses is divided *pro rata* monthly. The monthly total of horse-days is divided into the total costs for forage, horse shoeing, etc., to obtain the cost per horse per day.

Supplies, other than forage, are issued on the regular Storeroom Order Slip, signed by the stable foreman. Forage is requisitioned for monthly on the contract requisition. Theoretically, this forage passes through the storeroom as though an ordinary supply. No rations are fixed, but each foreman is allowed to use his own judgment as to the needs of his stock unless the cost records and the condition of the animals indicate the advisability of a change. Comparisons between the two stables are made each month, and each foreman is furnished with the costs in his stable.

Forage Records—Forage is drawn out but once each day (there being less possibility of error with the fewer drafts) and later subdivided for each meal. A record of the quantity used is forwarded daily to the main office on Forage Slips, and entered on the Forage Account, which is a perpetual inventory. Forage received at the stable is weighed, and the result sent to the main office with an inventory of the amount on hand, which is compared with the Forage Account, corrections made, and the amount received added. This corrects a small error in weighing and any losses. The foreman is always notified of this error, and an investigation is made if the amount is too great.

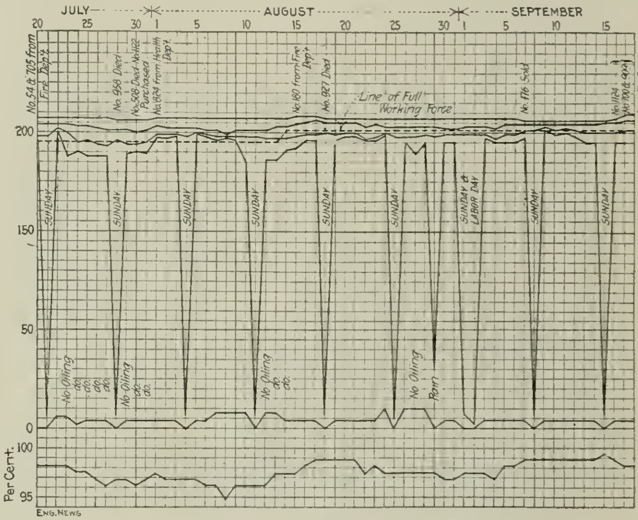

Fig. 5. Stable Profile

(Top curve shows total horses in department. Second shows number fit for work. Third shows second less those the stable boss considers in need of a rest. Fourth shows number working. Fifth shows number hired. Dotted line is line of full working force. Bottom curve shows efficiency of stable or percentage of horses fit for work to the total number.)

At the end of each month, this account is balanced and the cost of feeding determined. This information is transferred to the Forage Sheet, which gives a comparative statement of forage on hand, ordered and fed; the cost of feeding and the cost per horse per day for a 6-months' period.

Cost-Data Sheets

In compiling the data sent to the main office, Stable Expense is taken up first. The cost of the different gangs is materially affected by this expense. It is entirely independent of the efforts of the gang foreman, and unlike payrolls, continues whether work is done or not.

Stable-Expense Sheets—The Stable Expense Sheet gives the summation of data from the stable, storeroom and repair shop, reduced first to actual cost, per horse per day; and, second, to cost per working horse per day. The second is the first plus a *pro rata* charge for idle horses.

The actual cost per horse per day for forage, labor, shoeing, stable supplies and stable repairs is found by dividing the total costs of these items, obtained from the

Forage Account, the semimonthly Time Report, the Material Sheets and the Repair Sheets, by the total number of horse-days obtained from the Horse Distribution Sheet.

The cost of feeding idle stock must, of course, be borne by each gang in proportion to the number of horses charged to each. This necessitates a new figure for a cost per working horse per day. This is found by adding to the actual cost per horse per day the result of dividing the total idle-horse expense by the number of horse-days charged against all divisions of work as given on Horse Distribution Sheet.

The total cost of forage, labor, shoeing, etc., may be found either by multiplying the actual cost "per horse per day" by the total number of horse-days or by multiplying the cost "per working horse per day" by the number of working days.

SECTION COST SHEETS—On a printed Section Cost Sheet, all items of the expense previously obtained are assembled and arranged for each gang to indicate the total and unit costs of cleaning for each division of the work, as well as the unit cost of each item.

To obtain the item for Forage on this sheet, the number of horses charged to the gang on the Horse Distribution Sheet is multiplied by the average actual cost per horse per day for forage on the Stable Expense Sheet. In the same way, the items of Stable Labor, Horseshoeing, Stable Supplies, Stable Repairs, and those bracketed as Extra Horses, are obtained from the Horse Distribution Sheet and the Stable Expense Sheet.

The items for foremen, laborers and hired teams are obtained direct from the Semimonthly Time Report. The item for section supplies is obtained from the Material Sheets.

The items for section repairs and general repairs are obtained from the Repair Sheets. All rolling stock is permanently numbered and each gang assigned sufficient equipment for normal conditions. Repairs to this equipment are charged direct. Sufficient extra rolling stock is carried to replace any being repaired or to cover extraordinary demands. Repairs to such equipment are divided pro rata to the various gangs and charged as general.

WORK SUMMARY SHEETS—From a Work Summary Sheet, the actual number of [illegible] days worked, the calendar days worked and the area cleaned is obtained. Each item making up the total cost for the month is divided by the area cleaned, giving the detailed costs per thousand square yards, from which comparisons are made between the costs of different methods of work, one gang's work with another similarly engaged, and the same gang in previous months.

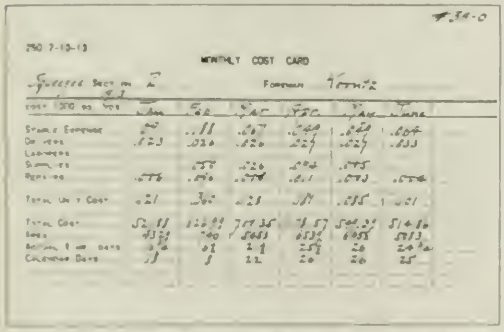

FIG. 6. MONTHLY COST CARD SENT EACH FOREMAN EVERY MONTH, GIVING COSTS FOR HIS GANG. ACTUAL SIZE, $7\frac{1}{4} \times 4\frac{3}{4}$ IN.

As this office study resulted in increased efficiency, an effort was made to secure the foremen's interest and coöperation by sending them each month on a Monthly Cost Card (Fig. 6), the principal features of the Section Cost Sheet, together with a letter indicating conclusions reached by office study, if important.

AUTOMOBILE COST SHEETS—The Automobile Sheet is a comparative record of automobile data. The item of supplies issued is from the Supply Sheets, the repairs from the Repair Sheets and the time from the Repair Shop Time Slips. Odometer readings are taken when tires are changed, and also at the end of each month, from which the mileage figures are computed.

SUMMARY SHEETS—A Summary Sheet assembles in convenient form, the information for all classes of work from the Section Cost Sheets and represents the total expenditures from the appropriation for street-cleaning work alone, the unit costs representing the first of the three totals referred to in the introduction.

Expenditures from the other appropriations are now brought in the account and the second and third set of unit costs previously referred to obtained. Direct charges are made wherever possible and other items divided *pro rata* according to their relation to the main charges. An annual Cost Sheet represents this account, the notes explaining the transactions. The figures for street cleaning have been obtained from the cost keeping, while those of the other appropriations have been taken from the accounting.

The error of the cost keeping, as shown on this sheet, amounts to about 1 in 1000. This account shows the excess of stock and equipment over that of the previous balance, the error, when the actual value of stock and equipment taken care of by the cost keeping is considered, amounts to only about 1 in 1900. This error is, however, positive and no doubt due to a considerable extent to the use of a slide-rule in working out cost data.

WORKING CHART—The Working Chart (Fig. 7) subdivides the Annual Cost Sheet into the cost-keeping records, which go into its make-up, forming a skeleton, not of expenditures, but of the cost-keeping system. This is emphasized in the original chart by printing secondary records in black, primary in red, office in brown, and those for which no special form has been provided—informal reports—in green.

The idea of this chart is purely a guide to the office, a record showing how the reports are being used and who is responsible for the making up of the different records. This feature of having, under each record, the name of the party responsible for its accuracy and upkeep has proved almost invaluable. Any question as to responsibility is immediately settled by referring to the chart and any change in form shows exactly what records must be altered to suit same.

CONCLUSIONS

That increased efficiency has resulted from the establishment of a cost system is plainly shown by the de-

creased unit costs in every class of work. No large outlay for equipment or labor was required and no changes in personnel were made in the development and application of the cost keeping.

At the present time, all the office force necessary to keep up the cost-keeping system is done by five men, the entire payroll amounting to less than $4000 per year. Previously, about $1500 per year was expended in keeping rcords now included in the cost system, such as statistics of quantities of work done, arrangement of schedules, etc. The printing is now done in the office and the labor employed included in the above figure.

The principal advantages of the cost system may be summarized as follows:

(1) Gives the detailed cost for each gang, for each class of work or for any particular feature thereof, in such form as to admit of direct analysis of any variation from previous costs or comparison between similar details of other work.

(2) In the same way, gives the result of any change in methods of working.

(3) Provides a means of determining the relative efficiency of foremen or laborers, a tangible record for educational purposes, giving in money the effect of any internal change in the make-up of a gang and means of competitive comparison between gangs.

(4) Gives records of intermediate costs, such as stable, repair-shop or office expense, in which the greatest possibility of saving lies, in terms which admit of comparison with other departments or firms, as well as inter-

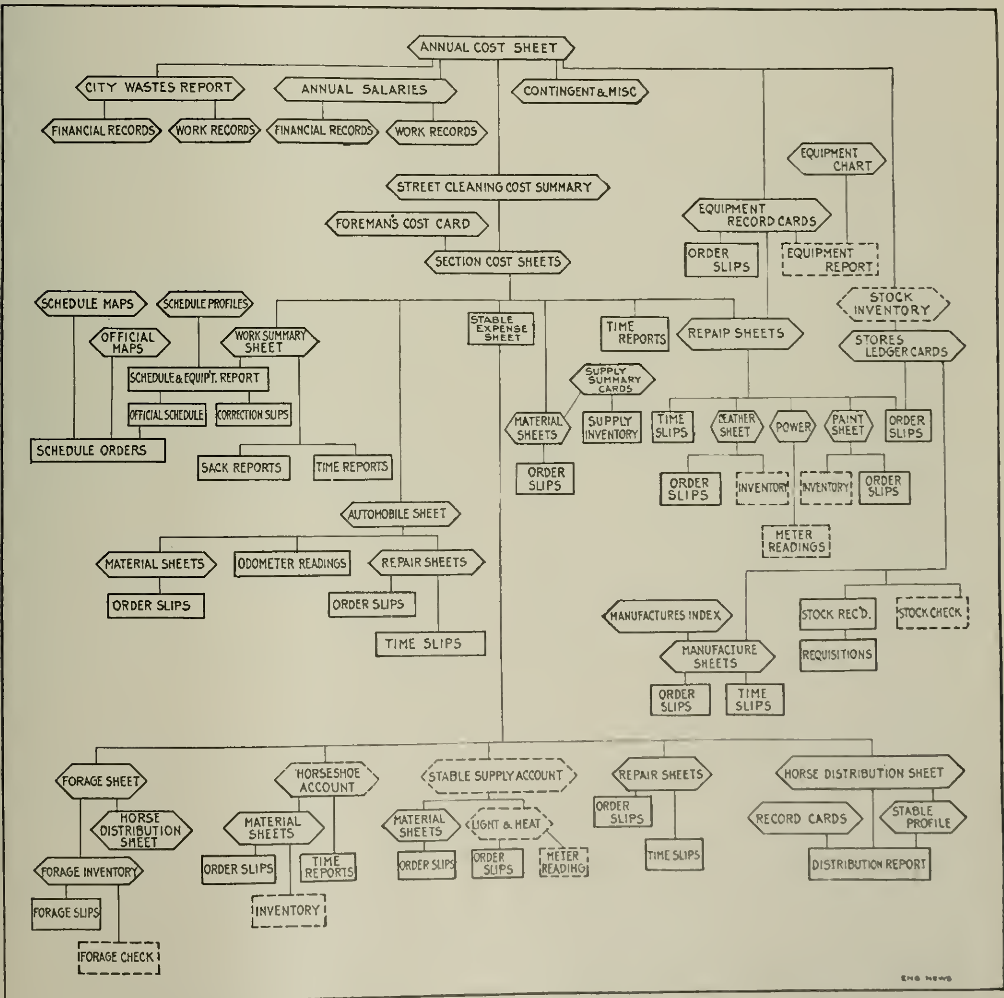

Fig. 7. Chart Showing the Different Records of the Cost-Keeping System and How Compiled to Make Up the Annual Cost Sheet

(Original records for which a regular form has been issued are shown in a solid rectangle. Informal original records are shown in a dotted rectangle; secondary records for which a regular form has been issued are shown in a diamond-shaped figure; while informal secondary records are shown dotted.)

and comparisons between two units, such as two stations of the same department.

(5) Gross repair costs, which in time, will admit of comparison as to relative efficiency of two similar pieces of apparatus of different manufacture, as well as a check on excessive repairs.

New applications are constantly coming up to keep the system alive. Often some new item will creep into a standard report, be investigated and result in a new train of thought and study, with increased efficiency and renewed interest, not only in the new feature but necessarily in the routine which is required to develop the working figures.

The Wisconsin State Building Code

By Sidney J. Williams*

Previous to 1913, Wisconsin state building regulations consisted of a few isolated statutes on fire escapes, exit doors, elevator shafts and scaffolds; a comprehensive tenement-house law, embracing both fire-protection and sanitation, for cities of the first class (i.e., Milwaukee); and a tenement-house law of limited scope for smaller cities. The fire-escape law, which was enforced by the Bureau of Labor (succeeded in 1911 by the Industrial Commission) gave insufficient protection when applied to some types of buildings, while in other cases it was so unreasonably rigorous that it could not be enforced.

In the prevention of industrial accidents, very good results had already been obtained under a statute which, instead of prescribing specific machine guards, etc., simply laid down the broad principle that all places of employment must be made reasonably safe, and empowered the Industrial Commission (subject to court review) to fix specific standards of reasonable safety. These standards or "general orders," being a creature of the Industrial Commission, could of course be altered, interpreted or suspended by the Commission at any time. As a result of this elasticity, and of the Commission's policy of having the actual detailed orders drafted by practical shop men and manufacturers, a great improvement in shop safety and sanitation was brought about without unnecessarily burdening the manufacturers or arousing their opposition.

The legislature of 1913 decided to apply this same method to the subject of building regulations. This was easily done by amending the statute mentioned in the preceding paragraph, to include public buildings as well as places of employment. The latter terms were so defined as to include practically all buildings except private residences; the term "safe" had already been defined to cover life, health and welfare. Specific statutes on fire escapes, etc., were repealed, with the single exception of the tenement-house law for Milwaukee, which had proved satisfactory. The way was then open for the Industrial Commission to formulate, adopt and enforce a comprehensive state building code on a much more elastic basis than is usually possible.

The Commission's broad power along these lines was subject to four limitations, which were really more beneficial than otherwise:

(1) The Commission's jurisdiction does not cover private residences.

(2) The code is confined to the protection of life and health. Ordinarily such protection must be sought by the same means, and with the same results, as the protection of property. There are some regulations, however, such as fire-limit restrictions and the limitation of the size of one-story buildings, which are a necessary precaution against a general conflagration, but are not necessary to the safety of the individual occupants. Such regulations cannot be included in the state code but must be covered by local ordinances.

(3) The code must be "reasonable." This statutory provision simply enforces, by the threat of court review, the policy which a wise commission would pursue in any case. It is the uniform policy of the Wisconsin commission to apply the criterion of reasonableness very strictly, not only to all its general orders, but also to the application of these orders to particular cases. The Industrial Commission will not order any safeguard on a machine or on a building, unless the resulting benefits will justify the expenditure. Under a rigid specific statute this policy would put the Commission in the undignified attitude (to say the least) of winking at a violation of law. Under the Wisconsin statute, as stated above, the Commission can legally follow the obviously businesslike policy of altering, interpreting or suspending its own rules if necessary in order to "make the punishment fit the crime."

(4) A very important practical limitation is that imposed both by the limited funds of the Commission and by its general policy, namely, that the code must be enforced largely by the cooperation of fire chiefs and other local officials. The statute requires all local officials to enforce the orders of the Industrial Commission; but efficient cooperation cannot be obtained with a club. The Commission has tried to insure such cooperation by sending copies of the tentative code to architects and fire chiefs throughout the state, for criticism, and by holding public hearings in several cities; and is prepared to make any reasonable modification in the code to meet local conditions. This may not make the Wisconsin code a technically perfect document, but the Industrial Commission feels that it is wiser to aim at 80 or 90% of the ideal and get it (or most of it) by peaceful methods as far as possible, rather than to ask for 100% and, by hard fighting, get perhaps 50.

This proposition, of the necessity of securing local cooperation, has an important corollary. The framers of the Wisconsin code believe that if the village (or small city) fire chief is to be expected to read, understand and sympathetically enforce the state code, it must be both easily intelligible and brief.

To make the code brief, only those points were covered which, under conditions actually existing or liable to exist in Wisconsin, constitute a real menace to life or health, and the emphasis is placed on the points which constitute the greatest actual menace. Readers of the code will thus find that fire-protection has received the most attention, sanitation the next, and structural design the least.

It is apparent from the foregoing considerations that the Wisconsin state code will not take the place of a local code in any city or village large enough to have fire limits.

*[illegible] Industrial Commission of Wisconsin, Madison, Wis.

Such a limitation of the scope of the state code is believed to be desirable. There is much truth in the common contention that differing local conditions require different treatment. Moreover, common sense and psychology agree that the best way to interest a man in anything is to give him something to do. The best way to secure the coöperation of local officials in enforcing a state building code, is to leave to them the task of working out local regulations to supplement the state code. The scope of such local regulations will depend on the size of the municipality; ranging from a simple fire-limit ordinance to an elaborate code which might include, among other things, detailed specifications on structural design and workmanship. In some particulars, e.g., the limitation of nonfireproof construction, the local code might well set a higher standard than was considered feasible for the state code. Even the smallest municipality will be encouraged to require building permits and will be assisted in working out a simple and economical system of building inspection. The Commission considered the advisability of requiring a state building permit, except in cities which require a city permit; but this was given up as being too obnoxious and irritating in localities where considerable missionary work is necessary to overcome the popular prejudice against any building restrictions at all.

The code was drafted by an advisory committee of architects, with the assistance of other architects and representatives of various interests. The Industrial Commission's building inspector, as secretary of the committee, handled the necessary correspondence and investigations, consulted with specialists on various subjects and drafted the various sections for discussion by the committee. Existing codes were consulted and used in varying degrees.

The code was first printed in tentative form and distributed for criticism. The discussions at the public meetings have brought out a number of suggestions; most of these deal with minor matters, and most of them will probably be accepted; none was really vital. No objection has been heard as to the general purpose and essential features of the code.

After all criticisms have been received, they will be considered by the building code committee, which will then make a final report to the Industrial Commission; the code will then be formally adopted by the Commission, probably about Aug. 1, and will become effective thirty days later.

Arrangement and Contents

The arrangement of the code was chosen with the object of making it as easily intelligible as possible. The first four "parts" apply to all classes of buildings; the last four take up the four classes into which all buildings covered by the code are divided, and give the requirements peculiar to each class.

Part I. Scope of the Code—This part briefly defines the application of the code to new buildings, alterations and changes of occupancy. The question of fire escapes and other fire-protection in existing buildings is not covered by the code but will be the subject of other "general orders" to be issued in the near future.

Part II. Definitions and Standards—Here are defined four types of construction—fireproof (wood floors and trim permitted), mill, ordinary (brick walls and wood-joist floors), and frame (including veneer). This part also contains specifications for standard fire escapes, inclosed fireproof stairways or "smokeproof towers," horizontal exits, etc.

Part III. General Requirements—In this part are included the usual limitations of height and area of buildings; minimum sizes of courts; construction, size, ventilation, etc., of toilet rooms; protection of boilers, furnaces, stoves, smokepipes, steam and hot-air pipes; and similar subjects. The most interesting section of this part, however, is one which provides that all buildings must be designed and supervised by competent persons. This provision has been criticized as being of no practical value, since there is no architects license law in Wisconsin, and since the Industrial Commission is hardly in a position to pass on the competency of all architects, engineers and builders in the state. It was felt, however, that a definite stand should be taken against the designing and construction of buildings by irresponsible parties, even though a complete enforcement of this regulation is impossible.

Part IV. Structural Design—This section gives permissible floor loads and unit stresses. Both are fairly conservative.

Part V. Factories, Offices and Mercantile Buildings—This is mainly devoted to the fire-protection of such structures, with an especially complete section on stairway requirements.

Part VI. Theaters and Assembly Halls—Existing theater ordinances offered plenty of material for this.

Part VII School Buildings, Libraries and Museums—Here again the fire escape and stairway requirements were the hardest problem, and are the parts to which most attention is desired.

Part VIII. Apartment Houses, Hotels and Places of Detention—This classification includes practically all buildings, except residences, in which persons sleep at night. The principal requirements are for fire-protection.

In the foregoing discussion, many features of the new Wisconsin code, relating to sanitation, ventilation, lighting, and other subjects, have not been mentioned at all for lack of space. The emphasis has been placed on fire-protection because that is actually the greatest problem which had to be met.

Experience will no doubt indicate the necessity of changes in and additions to the code, and may disprove some of the arguments developed in this article. When changes become necessary, they can be made without any legislative investigation or special machinery, thanks to the elastic basis which is the most important feature of the Wisconsin code.

A Reinforced-Concrete Pontoon, for a landing stage for ferry service, has recently been put into use in the Harbor of Sydney, Australia. The pontoon is 100 ft. long, 13 ft. wide at one end and 68 ft. at the other, 7 ft. 9 in. deep, with a 32-in. freeboard. The bottom is flat, and the sides and ends are sloped to an angle of 70°. Special attention was given to the design of the reinforcement, with a view to enable the construction to withstand the excessive strains likely to occur should vessels be berthing at each side of the pontoon at the same moment. In the construction of the top and bottom of the pontoon, allowance has been made for a live load of 150 tons, which will be distributed over the center length between the posts. The whole structure is divided into 48 water tight compartments by solid reinforced-concrete walls. It weighs about 650 tons. A view and a brief description appear in the "Commonwealth Engineer" for June, 1914.

A Box Type of Abutment for Subways at Memphis, Tenn.

By Paul D. Fuqua*

For some subways on grade-separation work, at Memphis, Tenn., a box type of combined abutment, curb pier and sidewalk span was adopted.†

The streets to be carried under the tracks were generally 60 ft. wide and the length of subways between right-of-way lines 100 ft. or over. As it was desired to reduce to a minimum the length of time during which trains would have to be operated over falsework and temporary tracks, it was decided to make the deck of slabs cast in a yard adjacent to the subway, these being set in place on the substructure after they had thoroughly seasoned. By adopting this method, it was possible to cast the slabs in advance and have them ready for use. The heaviest slab weighed about 40 tons and was easily handled by a 100-ton wrecking crane. Fig. 1 shows one of the large parapet slabs being placed in this way.

The city ordinance under which the work was carried out, provided that one line of supports be placed in the middle of the street and two at the curb lines. The designs for the first two subways to be constructed under this ordinance provided independent footings for the bents at the curb lines and for the abutments (which latter were of the counterfort type). With this type of construction (Fig. 1), it was necessary to cast each line of slabs in four sections, two of which covered the space between the curbs while the other two covered the sidewalks.

In the two following subways to be built, a box type of abutment was adopted, which combined in monolithic construction the three former subdivisions of curb bent, counterfort abutment and sidewalk slab. A typical design is shown in Fig. 2, and a section through the center line of one of the curb piers (which were spaced 8 ft. to 9 ft. apart) is shown in Fig. 3. Fig. 4 shows one of the subways under construction, and attention is called to the method of finishing the ends of the box-type abut-

*Assistant Engineer, Morgan Engineering Co., Dayton, Ohio.

†The subways are on a line of railway which extends along [illegible] Ave. toward the Memphis bridge. The two first subways with separate abutments and curb bents are at [illegible] Boulevard and Mississippi Boulevard. The two with box abutments are at South Third St. ([illegible] ft. long), and South Main St. ([illegible] ft. long), the length of the latter being due to a Y track connection to the new station of the Illinois Central R.R.

The right-of-way on Railroad Ave. is 100 ft. wide and the tracks were elevated in connection with the construction of the new union station, which was opened in 1913. This station is owned by the Memphis Union Station Co., of which W. F. [illegible] was Engineer of Construction, and he was also engineer for the Board of Control appointed by the four railways interested to represent them jointly in carrying out the track-elevation work and subway construction adjacent to the station. The box abutment design described in this article was designed by Mr. Fuqua while acting as Assistant Engineer under Mr. [illegible].—Ed. "Eng. News."

FIG. 1. CONCRETE SUBWAY WITH SLAB SPANS AT MEMPHIS, TENN.

(The wrecking crane is setting a parapet slab on one of the street spans. The sidewalk spans in this case are similar but smaller slabs.)

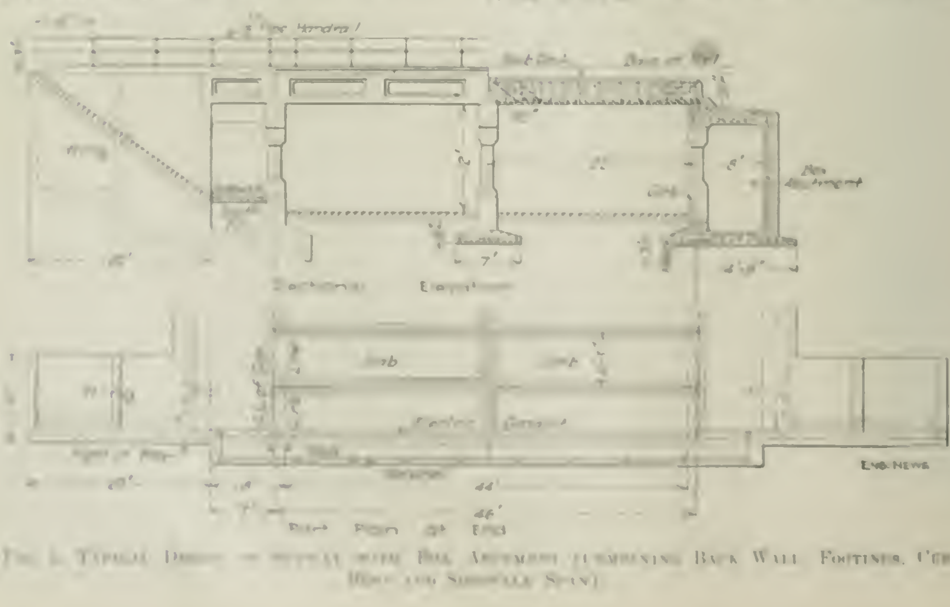

FIG. 2. TYPICAL DESIGN OF SUBWAY WITH BOX ABUTMENT (COMBINING BACK WALL, FOOTINGS, CURB BENT AND SIDEWALK SPAN)

ment. On the right side, the roof slab slopes up, and is paneled, which gives the bridge the appearance of having the slabs extend over the abutment. The falsework at this bridge was provided for four of the nine tracks which are normally operated over it.

In the comparative estimate made for constructing a subway 100 ft. long, and based on local prices for work,

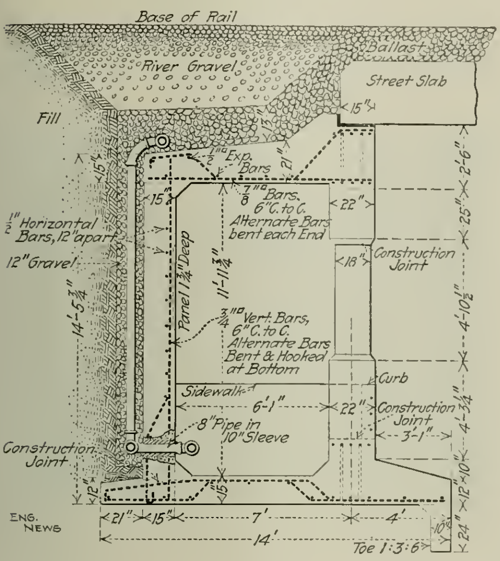

Fig. 3. Section of Box Abutment, with Drainage System

the saving in cost by adopting the box design in place of the design which provided independent curb bent, abutment and sidewalk slab, amounted to some \$1700. Among the items on which a saving was effected, may be mentioned the following:

1. The volume of excavation required was reduced by allowing the toe of excavation slope to be moved in from a point 7 ft. back from the face of abutment (with independent abutment) to a point 3 ft. back (with box-type abutment).

2. The volume of backfilling required after the abutment was finished was reduced by the amount of the excavation saved, some 6 cu.yd. per lin.ft. of subway.

3. A saving was effected in the cost of waterproofing the tops of the slabs by reducing the width to be waterproofed some 8 ft. over the sidewalks, on each side of the street. The cost of the waterproofing is usually 25c. to 30c. per sq.ft.

4. The cost of construction was reduced by an amount estimated at \$1 per cu.yd. of concrete on account of simpler form work, more massive construction, the fact that concrete could be placed and tamped more easily, and that the reinforcing steel could be bent and placed at less cost.

5. The yardage of concrete in the box-type abutment was about 1% less than in the construction which it replaced, although the sections were more liberally proportioned than in the design for the counterfort abutment. The latter provided shallower foundations, a face wall only 8 in. thick under panels, reinforced with only one set of reinforcing bars which were bent in at the counterforts and out in the slabs between them, to take care of both negative and positive bending moments.

6. A further saving was made in building the sidewalk slabs in place by eliminating the cost of setting them with the wrecking crane, which (under traffic) amounts to about \$1 per cu.yd. of concrete.

Among other comparative advantages which do not affect cost but which are highly to be desired may be noted the following:

1. A more impervious abutment wall is secured, on account of increased thickness and better tamped concrete. With the main reinforcing bars vertical, the stone in the concrete has much less tendency to "pocket" than when these bars are horizontal.

2. More impervious sidewalk slab construction is secured by building the slab in place, in that open joints at each end of the sidewalk slab, and between slabs at intervals of 6 ft. 3 in., are entirely eliminated.

3. There is better drainage, as indicated by Fig. 3. A pocket of gravel is provided over the sidewalk span, into which the water drains readily from the street spans. This water is carried off by a 6-in. vitrified-tile drain laid with open joints. Down pipes 20 ft. apart are laid in a 12-in. filling of gravel behind the abutment, each with an 8-in. pipe extending through a 10-in. sleeve in the wall, and an 8-in. vitrified drain at the back of the abutment.

4. There is an inherent advantage of monolithic construction over unit construction, in absorbing impact and vibration due to passing trains.

In the work described above, the superstructure was designed for a live-load equivalent to Cooper's E-55 load-

Fig. 4. Subway with Box Abutments Completed and Ready for the Slabs of the Street Spans

ing, with an addition of 50% of the live-load to cover impact. The substructure was designed to carry live-load plus dead-load with no allowance for impact. High-carbon deformed reinforcing bars were used. The percentage of reinforcement was arrived at by allowing a unit stress of 17,000 lb. per sq.in. tension in steel and 650 lb. per sq.in. compression in concrete.

The writer was employed on this work for 18 months as assistant engineer and made the design for the box type of abutment described.

The Ohio State Highway Department had already obtained over half a million dollars from automobile license receipts up to June 23 of the present year. The expenses of administration amount to less than \$100,000 a year, so that the Highway Department has already received five-sixths of the gross income from this source. Another \$100,000 is expected before the end of the year

Balcony Framing, McBride Theater, Victoria, B. C.

Some interesting balcony-framing features are found in the McBride Theater, recently built in Victoria, B. C., by the Victoria Opera House Company, Ltd. Following the general modern practice, the balcony is supported by a transverse truss, eliminating columns in the clear space of the auditorium below; radial cantilever girders resting on this truss and anchored to the back wall, support the balcony floor-beams. The radial girders are of unusually long overhang—up to 21 ft. at the maximum—and because of the mezzanine foyer below, they are of irregular shape.

The theater building is 90 ft. wide by 150 ft. long. The small-scale plan in the drawing herewith shows the arrangement of the balcony framing. The balcony-truss columns are set a short distance inside the side walls. The truss is 74 ft. 10 in. long c. to c. of end columns; its effective depth is about 8½ ft. There are seven radial girders of full length to back wall, and two auxiliary radials so located that they could not receive wall anchorage. The back end of each auxiliary radial is supported and anchored by a short loading girder in the plane of the floor-beams, while the middle of the radial is suspended from an 18-in. I-beam set just above the regular floor-beams and concealed under the second step of the balcony.

The end column just back of the boxes has the balcony fascia girder attached to it, but is stiffened in both directions, transversely by a beam connecting it with the wall column and longitudinally by a 15-in. floor-beam. The fascia girder is a light 18-in. plate-girder.

The Warren-system web of the balcony truss gives room for passing the radial girder between the chords, without interfering with the truss members. It is fastened by seat- and stay-gusset connections to the lower and upper chords. This position of the radial girder brings it considerably below the stepping of the balcony. In consequence, back of the balcony truss, where the mezzanine foyer required increased clearance, the line of the radial girder is offset upward, producing a reversed bend in the outline of the girder. The splices at the angles do not involve any particular complication.

The radial girders weigh about 6½ tons each. They were shipped and erected entire.

The balcony truss, whose makeup will be clear from the drawing, has its end panels sloped up, which gives it a sagging shape. Inclined passage-ways (in place of steps) from the street level to the balcony cross under the balcony truss at the ends at about the level of the bottom chord, and the headroom needed for these pas-

Fig. 2. Balcony Steelwork of McBride Theater, Victoria, B. C.

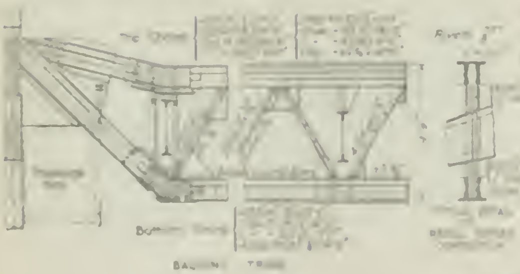

Fig. 1. Balcony Truss and Cantilever Girders of McBride Theater

sage-ways required the truss to be sloped up. Since the balcony floor is a curved surface, the clearance over the truss increases at the sides sufficiently to give ample room for the sloped panel.

The total weight of the balcony truss is 51 tons. The truss was assembled in the shop and all connection holes reamed to match, then knocked down, slipped in separate pieces, and erected in the field.

The roof and floors throughout the building are reinforced-concrete slabs with triangle-mesh reinforcing.

The McBride Theater cost $400,000. It is considered to be one of the finest buildings of its kind on the Pacific Coast. The steel framework has a total weight of 500 tons. The foundations are concrete piers through mud to bedrock, 20 to 50 ft. below sidewalk. They were constructed by sinking open cylinders and filling them with concrete after reaching rock.

Rochfort & Sankey, of Victoria, B. C., were architects for the theater, and H. W. Bittman, of Seattle, Wash., was structural engineer. Pinney & Mc Lellan were the general contractors, while E. E. Davis & Co. erected the steelwork.

Asphalt Paving Repairs in St. Paul, Minn., by Municipal Day Labor*

In 1912 the city of St. Paul, Minn., purchased a municipal asphalt plant at a cost of about $15,000. The plant consists of a Warren Bros. portable asphalt plant, one 8-ton asphalt steam roller, one scarifier, one Lutz surface heater, one fire wagon, one gyratory stone crusher, two portable melting kettles, six 2-cu.yd. steel-lined asphalt wagons, four ¾-cu.yd. concrete spreaders, one set of curb cutter's tools, nine asphalt rakes, testing scales, and the necessary small tools. The accompanying table gives an itemized cost of the plant.

	No.	Rate	Cost
Warren Bros., portable asphalt plant..	1	......	$4850
Steam roller, 8-ton....................	1	......	2250
Scarifier	1	......	365
Lutz surface heater....................	1	......	1800
Fire wagon.............................	1	......	112
Melting kettles........................	2	$425.00	850
Asphalt wagons, 2 cu.yd...............	6	171.50	1029
Concrete carts, ¾ cu.yd................	4	117.00	468
Koehring concrete mixer, No. 14.......	1	......	1950
Tandem steam roller, 8-ton............	1	......	2200
Koehring paver, No. 14................	1	......	1900
Chain belt paver, No. 15..............	1	......	1770
Chicago concrete mixer, No. 5.........	1	......	481
Tinius-Olson brick tester.............	1	......	475

The plant was put into operation Apr. 25, 1912, and during the season of 1912 was worked a total of 92 days. The amount of asphalt pavement turned out during the season was 19,428 sq.yd.; 15,040 sq.yd. of this was cut out work and 4388 sq.yd. burner work. Besides this, 5459 sq.yd. of asphalt pavement were put down for paving contractors in repairing pavements built under a guaranty; of this, 2363 sq.yd. was cut out work and 3095 sq.yd. burner work. The total cost was $6013, which was charged to and collected from the contractors.

All asphalt-paving repairs during the year 1913 were made by this municipal asphalt plant. The plant was put in operation March 30, and during the season worked 178 days. Asphalt paving to the amount of 44,191 sq.yd. was turned out; 43,296 sq.yd. of this was cut out work and 897 burner work. Asphalt repairs for contractors were made to the extent of 16,832 sq.yd., of which 16,039 sq.yd. was cut out work, and 793 sq.yd. was burner work.

*Data from recent report of Commissioner of Public Works.

The total cost was $21,613, which was collected from the company which had guaranteed the pavement.

For the City Ry. Co., 7370 sq.yd. of asphalt pavement were laid, and the cost, $11,031, collected from the company. For other public-service corporations, 1250 sq.yd. of asphalt pavement and 118 sq.yd. of concrete foundation were laid. This work cost $2340, which was collected from the various corporations.

About 246 sq.yd. of asphalt pavement was laid on bridges on which the city maintains the wearing surface; this cost $430, and was charged against the bridge building and repair fund at $1.75 per sq.yd. Small repairs were made for other city departments and charged against those departments at $1 per sq.yd. The repairs to asphalt pavements on which the guaranty period had expired and for which the city paid, amounted to 14,487 sq.yd. of cut out work. This repair work cost the city $18,490, an average of $1 per sq.yd.

The following shows cost and relative data regarding asphalt repairs for the year 1913:

Total area of pavements on which repairs were made in sq.yd..................................	222,327
Area or repairs in square yards................	18,733.18
Per cent. of area repaired.........................	8.42
Cost of repairs..	$18,921.34
Average cost per square yard of total area.....	0.085

Cuts in asphalt pavement made by the City Water Department, heating, lighting and telephone companies, sewer contractors and others, were repaired, at a cost of $2340, which was collected from the various companies.

Cost of Operation—The operating crew at the plant consisted of one foreman, one engineman, one tank man, four laborers, and a night watchman. Four teams were employed hauling asphalt from the plant to the work.

The street crew was made up of one foreman, one timekeeper, one roller man, two rakers, two tampers, one smoother and one cement man laying new pavement; and two shovelers, six scrapers and two teams removing and hauling old paving. The total expense was divided as follows:

Operation of plant, labor........................		$5,889.02
Fuel		1,024.47
Hauling material		1,559.18
Superintendence, livery, watchman, etc		3,164.21
Repairs and supplies.............................		1,658.05
Material		26,876.59
Street crew labor.................................		8,206.66
Hauling material to street.....................		5,068.40
Engineer and watchman.........................		1,391.65
Tools, repairs, etc................................		790.05
Total		$55,628.28
Total labor	$25,175.66	
Total material	30,452.62	
		55,628.28
Charged to outside parties	$34,194.23	
Charged to bridges................................	430.49	
Material on hand.................................	2 512.71	
		37,137.43
Total cost to city of work........................		$18,490.85

Municipal Motor Cars versus Horse Vehicles—The city of Fitzroy, Victoria, Australia, recently installed a motor truck instead of a horse-drawn vehicle for the collection of refuse. A recent report gives the comparative figures of the motor-truck and the horse-drawn truck operation as follows:

For the six months ending Mar. 31, the motor truck, working 110 days, had taken 995 loads (3483 tons). It had run 4923 miles at a cost for gasoline of 4.48c. per mile. The total cost of the service, including interest, depreciation, employment of extra carts when the motor was not running, etc., was $6340. For the corresponding six months of the year previous, the horse-drawn vehicles, eleven in number, which did the same amount of work as the one-motor truck, cost $5670, so the cost of the motor truck was $670 greater than the horse-drawn vehicles. The officials state that in their opinion the motor effected a greater saving than is shown by the figures. They say that the truck had not been used in the way for which it was intended, and has taken on more work than the vehicle it displaced.

The Throttle Dam, Raton, N. M.; an Earth Embankment for Sudden Flood Waters

The most irrigation projects' dependence in reservoirs is gradual throughout the entire wet season. For such conditions a definite percentage of the seasonal rainfall may be assumed as a reasonable basis for computing the amount of water available for storage. The Throttle Dam, on the ranch of Thompson and Malche about 15 miles southeast of Raton, N. M., was constructed to store the water of heavy freshets, where, owing to the nature of the catchment area, the total runoff occurs within a period of a few hours. Several prominent engineers reported unfavorably on the project, not daring to risk the construction of this type of dam at a site that was subject to freshets of over 15,000 sec.-ft. However, the embankment as built has stood without serious injury, despite the fact that twice during the course of construction, when the dam was two-thirds completed, flood waters poured over the crest and submerged practically the whole structure.

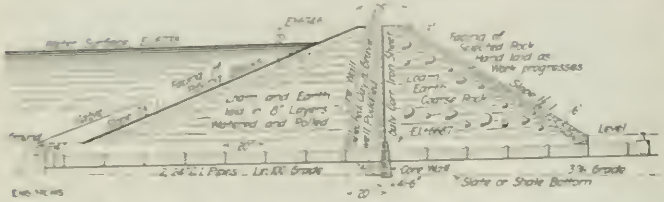

FIG. 1. DETAILS OF THROTTLE DAM NEAR RATON, N. M.

The purpose of this construction was to conserve water for irrigating portions of a 57,000-acre ranch where a prolonged dry period would mean the extermination of many head of cattle and stock. The reservoir has a capacity of 4000 acre-ft., which will be replenished twice during ordinary seasons. On the watershed above the dam site the average annual rainfall is 15 in. The catchment area is 58 sq.mi. It contains at the higher levels a large mesa which is so flat that in ordinary light rains there is practically no runoff from the cultivated lands thereon. The remainder consists of creek gorges. The rapidity of the runoff results partially from the steepness and bareness of the sides of these gorges, and partially from the fact that most of the rain storms are torrential. An investigation was made as to the feasibility of digging a diverting ditch $1\frac{1}{2}$ miles long to lead flood waters for irrigation, the attachment from about 30 sq.mi. of the upper drainage area, to a desirable reservoir site on an adjacent mesa outside the shed. This plan was abandoned because it would be impracticable to make the ditch sufficiently large to divert even a considerable fraction of the freshet runoff, and due to seepage and evaporation such a ditch would be almost dry except at times of heavy downpour. The estimated cost for a ditch of this character was $44,900.

DESIGN

The Throttle Dam (Fig. 1) is 1060 ft. in length along the top and 77 ft. in height from the lowest point in the foundation to the crest. A concrete core-wall 600 ft. in length, $1\frac{1}{2}$ ft. wide at the base and $2\frac{1}{2}$ ft. at the top extends from bedrock to a height of $17\frac{1}{2}$ ft. In front and above this is a puddle-wall of selected clay and gravel, of the dimensions shown on one of the drawings.

FIG. 2. VIEW LOOKING ALONG THROTTLE DAM DURING CONSTRUCTION

Fig. 3. Downstream Side of Throttle Dam, after Overtopping
(Only damage caused by flood was a small area old riprap washed out.)

This is completely faced on the downstream side with No. 12 gage galvanized corrugated ingot iron which extends from the concrete core-wall to the crest of the dam. The sheets composing this facing are 6 ft. long, have a side lap of 2½ in., a vertical lap of 4 in. and are riveted both ways with ⅜-in. rivets at 2¾-in. centers. The object of this sheeting is to prevent rodents from boring through the structure.

Upstream from the puddle wall the embankment consists of loam and earth thoroughly rolled and compacted, faced with basalt paving blocks having a uniform exposed surface, a minimum depth of 12 in. and a minimum weight of 50 lb. each. In the downstream portion, large rocks were compacted with the loam and earth and a rough rubble facing of rock 3 ft. thick at the crest and 6 ft. at the base was hand laid to a slope of 1½ to 1. Large trapezoidal spillways were provided on both ends of the dam, as shown in one of the drawings. Cutoff walls and aprons for the spillways were lined with concrete.

Intake Control

Water is drawn from the reservoir through two 24-in. cast-iron bell-and-spigot pipes, incased in concrete, carried from bedrock through the base of the dam, laid on a 1% slope. No gate tower was erected over the intakes but an auxiliary emergency device arranged by which the flow could be controlled from the crest of the dam. At the reservoir end of each 24-in. pipe a quarter-bend elbow is attached and turned upward so that the intake is horizontal. In the open ends of the elbows are fitted cast-iron valve caps which may be lifted to permit the inflow, by means of a plow-steel cable 1⅛ in. in diameter. This cable is led over 24-in. sheave wheels to a multiple-pulley windlass on the dam crest (Fig. 4). The amount of water drawn through the intakes is controlled by two 24-in. valves in an ice-proof shed located 141 ft. 7 in. downstream from the center line of the crest. This type of control is more economical than providing an intake tower within the reservoir, as very heavy construction would be necessary for such a tower to be able to resist the impact of large masses of floating ice, frequently 24 in. thick, common in that locality.

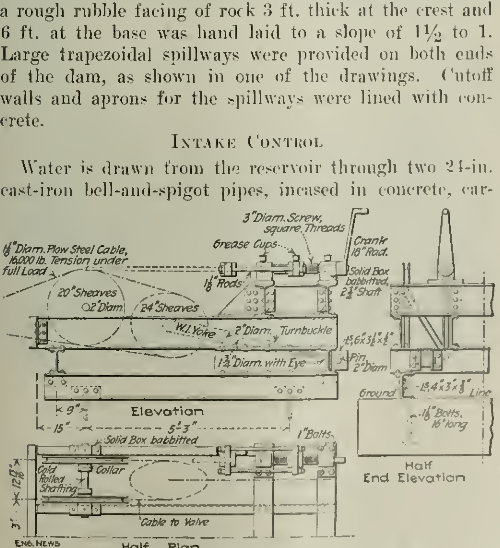

Fig. 4. Details of Sheave Control of Intake at Top of Dam

Construction

Earth and rock for the embankment were excavated from the adjacent hillsides with a steam shovel. This material was conveyed to the dam in 2-yd. dump wagons (Fig. 2). The earth was spread in 8-in. layers with wheel and Fresno scrapers and thoroughly wet by hosing. A four-horse roller weighing one ton per lineal foot of tread and consisting of a number of railroad car wheels, compacted this material.

Concrete for the core wall was mixed in a 1-yd. batch mixer. The proportions were 1 part cement, 2½ sand and 5 crushed rock. A special alkali-proof, slow-setting cement was first used, but although the proportions were accurately measured and care taken in mixing, it was discovered that after the concrete had been in place for five weeks it showed no signs of setting, and fell apart from its own weight when exposed to the action of seepage water. This defective concrete was removed, the cement condemned as unsatisfactory, and a standard portland cement substituted. No trouble was experienced with the latter brand. The reservoir has been filled to

the spillway level, and there is absolutely no leakage through the structure.

The cost of the dam and appurtenances was approximately $50,000. M. M. O'Shaughnessy, acting as Consulting Engineer, was in charge of the design and construction. The work was done by day labor under his direction. H. W. Blackburn was Resident Engineer.

A Machine for Laying Brick or Block Pavements

A machine has been designed and patented which will level, smooth and compact a sand or wet concrete base and lay automatically consecutive rows of brick or other kind of paving blocks, closing the joints, rolling the paved surface and leaving it ready for the joint-filling operation.

The machine travels on rails, laid carefully to a correct grade, on both sides of the strip to be paved. It is obviously intended only for straight stretches of uniform

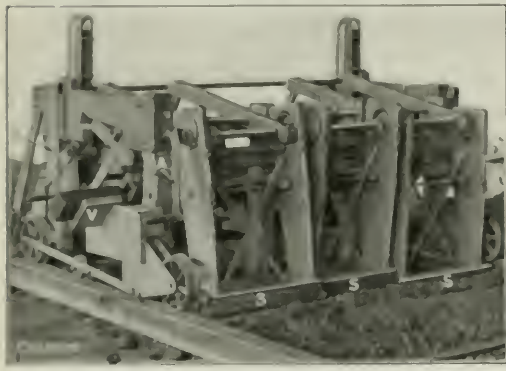

Fig. 1. Front View of Experimental Paving Machine Invented by William Bayley

Fig. 2. Side View of Bayley Paving Machine

kinds of paving. If the machine is motor-operated, the only manual labor necessary, other than that required of the operator, is the feeding of the blocks into V-shaped troughs on the sides of the machine.

The illustrations, Figs. 1, 2 and 3, show the front, side and rear, respectively, of an experimental machine built to lay a 6-ft. strip of paving. The front has three separately operated shovel edges S, which by means of cams and levers have a shoving and up-and-down motion which rolls the sand or wet concrete ahead of the machine and smooths and prepares the bed in advance of the bricks. The shovels can be detached from the links on the rocker and thrown over the shaft on top of the machine, so that any cleaning up can be done, as when commencing or stopping work. The V-shaped trough V (at the left on Fig. 1) is for feeding the blocks into the machine, which, in the case of this experimental one, is operated by turning the cranks A and B by hand.

Operation—To make clear the operation of the paving machine reference to Figs. 4, 5, 6 and 7 is essential. Fig. 4 shows the swivel arms 3 in normal position. The front shovel 4 is moving the loose sand or concrete ahead, and the back one 6 is acting as a tamper and smoother. The block box 1 is shown full with a row of blocks. The dotted line 7 is the path of the blocks 2, while in the act of being placed. The links 8 and 9 and the bent connection 10 swing from the block placer, being hung on shafts 11 and 12. They lift the block placer by means of contact with the stop angle 13, which extends across the machine. There are three sets of these links and connections on the machine.

When the block-placer descends to the position shown in Fig. 5, the fingers 14, which are attached to the hinged angle, or box end 15, come into contact with the shaft 17, which arrests the descent of 15, whereby the continued descent of 1 opens the rear end of the block-box and prepares a way for the blocks to pass out.

The box-front 15 is hinged at point 16. The box-frame 1 continues to descend and opens the block-box until the position shown in Fig. 6 is reached. The box 1 is now on the paving bed and has reached the end of its movement and has delivered the row of blocks on the paving bed, abutting those previously laid; except that the bottom plate 1 is still under the row.

Fig. 3. Rear View of Bayley Paving Machine

The bottom plate 1 is rigidly attached to the beams 37 as well as to the angle 18, which has an end extending out over the track at each side of the machine. These ends stop the movement of the beams 37 and the block box 1, as well as gage the position of the row of blocks from the tracks.

The links 8 and 9 and the arms 10 with the connection 10 continue to swing back away from the stop angle

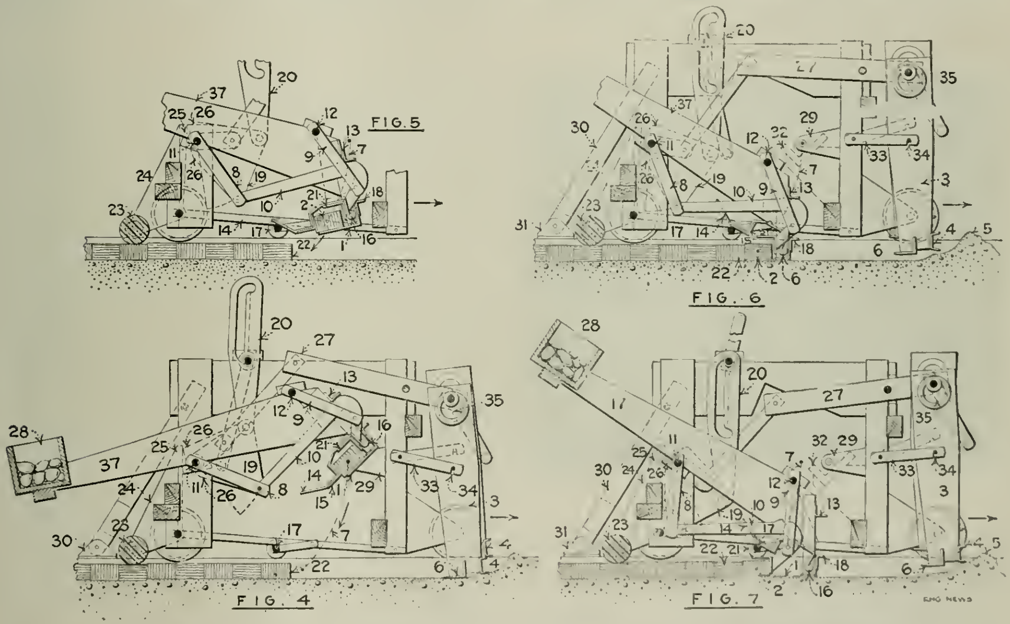
15, being propelled by the arms 19, which are on each side of the machine and are moved by the racks 20 until the end of the rack movement is reached, as shown in Fig. 7.

The angle 21, which extends across the machine and forms the front of the block-box, and is connected to the ends of connection 10, has pressed against the row of blocks 2 continually through this last movement, the whole machine is advanced by the pressure exerted against the shaft 11. Or in other words, the lower centers of links 8 and 9 and arms 19 remain stationary along the paving bed while the top centers, shafts 11 and 12 and the frame of the machine holding them, move forward.

This withdraws the plate 1 from under the row of blocks and passes the angle 15 over them. It will be seen that the row 2 has passed out of the machine, but by reason of the pressure exerted against it by the angle

In Fig. 6, the shovels 4 and 6 are being raised away from the paving-bed by the arms 27, until, as shown in Fig. 7, they have reached their greatest height. This raising movement prevents the shovels from being shoved into the mass of material in front of the machine and thus choked, but allows them to move this material forward gradually by taking off the top in small quantities, and gradually ramming down and finishing the bed. This is an important part of the working of the machine, for it is designed not only to make a good solid true bed, but to divide up the work of the machine so that when it is shoveling it is not placing blocks, and when placing blocks it is not shoveling.

In Figs. 4-7, the part 28 is a counterbalance box for the block placer; 29 is a stop for feeding the blocks into the machine. This experimental machine is fed from one side, but larger machines will be fed from both sides against an automatic adjusting stop in the center and by



Figs. 4-7. Showing Various Steps in Operation of Bayley Paving Machine

21 it is still clamped between angle 21 and the row of blocks 22 already laid. Hence, there is a clean, close joint between the rows 2 and 22, and row 2 is held suspended until the reverse action of the rack 20 takes all the parts back through the different positions shown by Figs. 4, 5 and 6.

As the machine is advanced, the roller 23 settles each row in turn, with all the pressure that is possible to put upon it. The roller 23 runs on its own wheel on the track. It is trailed from the rear axle of the machine by arms 24. These arms 24 have extensions 25, which come in contact with cams 26 at each end of the movement of the arms 19, of which the cams 26 are a part. Heavy contact at this point lifts the rear wheels from the track about 1/8 in. and thus throws all the weight of the rear of the machine on the roller and settles the blocks effectively.

two or more men. The part 30 is a pawl to resist backing and opposes the tendency of the shovel to back up the machine. The links 33 can be raised off of the pin 34 and turned up over the eccentric 35. When this is done, access is had to the paving-bed back of the blocks.

It is evident that the machine may be used for leveling cement or bituminous concrete as well as for laying blocks. To date, it has been used only for some factory floors, shown in the accompanying views, Figs. 8 to 10. It is claimed to be particularly adaptable to bedding brick or blocks directly in the soft concrete base, without the use of a sand cushion. In the views of the machine shown, it is being operated with asphalt blocks 5x12x3 in.

Two men working with this experimental machine laid 135 sq.yd. of brick pavement in a 9-hr. day, or at a labor cost of 3.67c. per sq.yd. With motive power, it is estimated that the cost would be about half. The

FIG. 9. CONCRETE PAVEMENT LAID WITH BAYLEY PAVING MACHINE

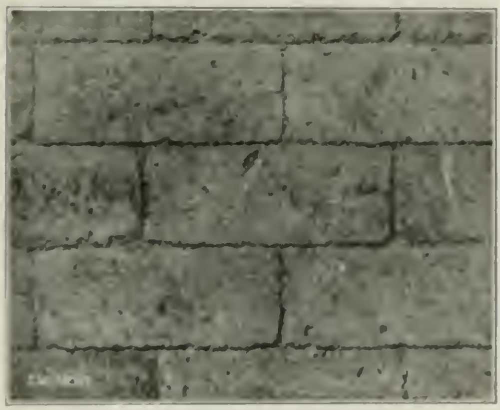

FIG. 10. ASPHALT-BLOCK PAVEMENT, SHOWING CLOSENESS OF JOINTS

speed at which the machine operated was limited by the speed with which the cement grout could be delivered in front of it. A larger machine would have an automatic block, or batch feeder, which would also economize time.

The apparatus described is known as the Bayley Paving Machine, invented and patented by William Bayley, President of the William Bayley Co., steelwork manufacturers, Springfield, Ohio.

Cement Joints for Sewer Pipe at Edmonton, Alta.

By J. M. Rose*

The difficulty of getting in Edmonton a sufficient number of skilled pipelayers and inspectors has led me to consider carefully possible methods of making cement joints in sewer pipe. It is a simple series of operations and, yet like many other simple things it is not always well done. Perhaps it is just because it is a commonly easy part of the work, that it is apt to be overlooked.

*Assistant City Engineer in Charge of Sewers, Edmonton, Alta.

Once a sewer is covered up, and the sewage entering it gets away freely, it is assumed that the sewer is in good working order, but that is not always so. The sewage may be getting out, or ground water may be getting in to an extent that seriously decreases the capacity of the sewer.

The common method of specifying sewer joints is to require a strand of oakum or hemp gasket all around the inner part of the joint and cement mortar to fill up the rest of the jointing space. The gasket prevents the mortar from entering the barrel of the sewer. In making a joint of this kind, the usual procedure is to dig a hole under the bell of the pipe last laid, insert the next pipe, calk the gasket all round the joint and complete the joint with cement mortar, using the hands to get it in under the pipe. From Ogden's "Sewer Construction," I take some directions typical of those which cover this method:

> All pipes and specials shall be laid to the grade given by the engineer . . . special care being taken that there is no sagging of the spigot end in the hub. . . . A narrow gasket of jute shall be provided by the contractor, to be well soaked in neat cement grout and introduced between the bell and spigot, and well and properly rammed. It shall in all cases be driven to the bottom of the hub to leave room for the mortar as specified. The space between the spigot and hub shall then be entirely filled with mortar thoroughly pressed in on the bottom sides and top and every precaution taken to secure a water-tight joint. The mortar shall be applied with a rubber mitten and rammed or compacted with a wooden calking tool. The joint shall be finished with a neat and generous bevel made with the mitten.

A careful and conscientious pipelayer can make an excellent joint in this way, but it is obvious, that, if he is at all slovenly, the lower half of the joint, which in a sewer is the vital part, is more likely to suffer. It is the most difficult part to get at, and the larger the pipe the greater is the difficulty. The danger is increased if the contractor is pressing the pipelayer to get along quickly and if the inspector is inclined to keep to the top of the trench. From that position he cannot see what the pipelayer is doing with his hands under the pipe. On a small job, where there is ample opportunity for careful inspection, and time is available, the method is not likely to be found unsatisfactory, but with thirty or forty miles of construction to cram into six months, I have found it apt to break down here and there.

If the pipelayer has any latitude at all, as often as

not he backslides and adopts another and easier method. Before laying any pipe, he places some mortar in the lower part of the bell of the pipe already laid, inserts the next pipe, and then finishes the upper part of the joint with oakum and cement, or with cement alone. Such a method leaves little chance of a leaky joint below the water run, but another danger is incurred. In the very act of inserting the pipe, the pipelayer is likely to squirt some of the mortar into the barrel of the sewer. This mortar, of course, can easily be removed with a scraper or a tight-fitting bag, but the pipelayer again may neglect to do this and the inspector may fail to detect it in one or two lengths.

I do not see how one can avoid running one or other of these two dangers. The engineer, who cannot always be on the job himself, can only choose the method that seems to him to offer the least chance of being carelessly carried out. The one method—calking oakum all round the joint before adding any mortar—involves the risk of a leaky joint, owing to the irksomeness of getting mortar into the bottom; the second method—placing mortar in the bell before introducing the next pipe—involves the risk of cement getting inside the sewer and forming a little ridge across the water run. In spite of this possibility, I have come to think this latter method the less dangerous. As a rule, not a great deal of cement does actually squirt through into the sewer, and the pipelayer has little temptation to omit cleaning out what does get in. Incidentally, I prefer the wooden scraper to the bag hauled through the sewer with a rope as pipelaying proceeds.

But many engineers who specify this method of first lining the bell with cement overlook an important point. Cement mortar alone in the bell will not support the spigot end of the next pipe. The spigot sinks down into even the stiffest mortar, and if the whole line is laid in this way you get a water run like the edge of a saw. Very little pressure is required to squeeze down the pipe into the bell. If the pipelayer steps on the pipe or if the backfilling is thrown on top of it while the mortar is green, it is enough to cause it to sag, even if the weight of the pipe itself does not carry it down. It is advisable, therefore, to lay a piece of hemp, about 6 in. long, on the lower part of the bell and then place the mortar on top of it. This may seem a clumsy proceeding but, if you try to introduce the hemp afterward, you will find you need to calk it away into the bell to raise the pipe, and in the larger diameters it is hard to raise the pipe in such a way at all. To raise the pipe with a chip of wood in the bell will not do as it lifts the spigot off the mortar, and any method of making the pipes concentric which depends on a finical trimming of the trench is not likely to be very successful. Hemp gasket is about the best and handiest material, but just before being used it should be dipped in neat cement grout.

In his "Engineering Work in Towns and Cities" (1908) Ernest McCullough quoted from Engineering News a specification which reads in this way:

Joints shall be made as follows: (1) Line with mortar the lower third of the entire circumference of the bell; (2) insert the pipe to be laid and a jute gasket freshly dipped in neat grout; (3) bring the pipe to grade and line, (4) calk the gasket tightly into the joint; (5) fill the joint with mortar mixed rather stiff, using a rubber mitten (6) tamp mortar into joint with an approved tool until it is solidly filled, (7) smooth on mortar, using a rubber mitten; (8) protect the cement (preferably with burlap) and all around the barrel of pipe with sand or similar material, tamping solid with an approved tool, (9) remove burlap and cover joint and pipe with fine material, (10) clean out and point joint on inside of pipe.

This is a better clause than is found in most specifications, though the manner of conducting operations (2) and (3) is not very clear. Mr. McCullough, in a note, states that he fails to see the necessity for specifying a gasket in sewer-pipe joints, except when the sewer is laid in water. But, as a few minutes' experimenting on the ground will show, it is difficult to get an even water run without the gasket in the bottom. The gasket in the top half of the joint is, of course, a safeguard against cement getting into the pipe. It may be argued that as we have to clean out any cement that gets in at the lower part of the joint, a little from the upper part will not materially add to the danger; but it is advisable to reduce the danger to a minimum.

The following is the specification we use at present in Edmonton:

The ordinary joint shall be made in the following manner:

(a) Lay along the lower quarter of the bell and just at the entrance a piece of Russian hemp or other approved material freshly dipped in neat cement grout. This hemp is to keep the pipe to be laid next from sinking into the mortar in the bell and must therefore be thick enough to keep the pipes concentric.

(b) Line the lower third of the bell with stiff mortar, covering completely the strand of hemp.

(c) Insert the pipe to be laid, pushing it home until it is hard against the inner end of the bell. Great care must be taken to see that the spigot end of the pipe rests on top of the hemp and does not catch it and jam it back into the bell.

(d) Calk into that part of the bell not already filled with mortar a strand of gasket freshly dipped in neat cement grout. This gasket after calking must not take up more than one-quarter of the space available in the bell for the whole joint.

(e) Fill the joint all the way around with stiff mortar, using a rubber mitten, and finish off the outside of the joint both top and bottom with a neat bevel. But no joint is to be completed in this manner until at least two joints have been calked in advance with the gasket as described in paragraph (d).

(f) Clean all cement from the inside of pipe up to 15 in. diameter by using a wooden scraper made in the form of a semicircle. Pipes over 15 in. and less than 22 in. diameter to have the lower half of the joints pointed on the inside. Pipes 22 in. diameter and over to have the joint pointed all the way around on the inside.

The method so specified is no doubt open to criticism but it is an attempt to work out a method which, taking full account of human nature and the actual conditions of pipelaying, should reduce the danger of leaky joints to a minimum. The trouble is not that a contractor may be dishonest. A good joint can be made about as easily and cheaply as a bad one. The trouble is simply that the pipelayer may find it awkward to make the bottom of the joint carefully and it is important to have a standard method that insures easy inspection and leaves as little room as possible for careless workmanship. There is nothing in the method suggested which a contractor could consider a hardship. It is easier than the method of calking a gasket all the way round before adding the cement, and it takes the same material. The latter method is almost sure to lead to leaky joints, if inspection relaxes for even a short time, or if the work is at all hurried.

It might after all be argued that the method I have recommended needs rigid inspection just as much as the other. It does need careful inspection, but this much at least can be said for it that once a pipelayer becomes accustomed to it there is little or no temptation to depart from it even if the inspector's back is turned.

Field and Office

Trenching a City Street for a 15-ft. Sewer

A very large trunk sewer in the Borough of Brooklyn, New York City, is being constructed, through some of the older sections of the city, with so little interference to street traffic that quite a thorough search of the locality has to be made to find the places where work is under way. Although the trench occupies nearly the full width

Fig. 1. Traveling Steam-Hammer Piledriver

of the street and is about 30 ft. deep in some places, the work is so expeditiously handled that less than a block is open at any one time. Within that distance, the excavating is made, the 15-ft. diameter reinforced-concrete arch sewer is built, and the backfill made simultaneously.

Driving the Sheeting—The timber sheeting is driven on both sides of the trench at the same time by two steam-hammer piledrivers, taking steam from a portable 30-hp. boiler and is taken through pipe and flexible hose connections. The piledrivers are mounted on travelers (Fig. 1) which run on light rails parallel to the trench.

Over the trench, on the top braces of the sheeting, are laid the rails which carry the light-steel trestle (Fig. 2) of the sewer-trenching machine; each post of the trestle is mounted on a wheel, which enables the whole outfit to be moved forward. The diagonal timber braces were added to the trestle framework by the contractor to give additional rigidity.

Trenching Machine—The illustration (Fig. 3) shows a Potter sewer-trenching machine (described in Engineering News, Apr. 28, 1898), which has been used considerably throughout the Middle West, but is little known to many Eastern contractors. This machine consists of a hoist traveler carried on the light-steel trestle shown in Fig. 2.

The traveler with loaded buckets is moved rapidly to the rear by a cable which starts from the upper drum of a 7x10-in. hoisting engine (in the shack at the left), passes along the trestle over the traveler, around a tail-block pulley or sheave at the far end of the trestle, and returns to the traveler, where it passes around a bull wheel, to which it is attached. Another cable starts from the lower drum of the hoisting engine and goes directly to an eye or ring on the front of the traveler. This cable holds the traveler stationary while the buckets are raised and lowered, and pulls it forward after the loaded buckets have been dumped. The buckets are raised and lowered by the main cable winding and unwinding on the bull wheel.

The traveler is moved by the engineman in the shack on signals from a man on the traveler. The buckets are cylindrical in shape, and hold 1 cu.yd. They are managed by the man on the traveler.

Excavation—The excavation is chiefly in sand. The earth is excavated by hand and raised in the buckets, 12 of which are constantly in use; two buckets at a time are run back on the traveler and dumped into one of two hand-pushed 2-cu.yd. tip cars, running on a narrow-gage track laid on the planks over trench bracing of the completed sewer and backfill. The cars are handled and dumped by two men. There is very little loose earth to be taken care of, for after the material from the first cutting is taken away the material from the remaining excavation is dumped directly into the backfill as fast as it is excavated.

The excavation amounts to about 30 cu.yd. per lin.ft. of trench, and the machine handles about 250 cu.yd. per [illegible] 8 hr., or makes a progress of 8 ft. of sewer per day, with a force of about 60 men.

Concreting—Following the piledrivers, on the left-hand side of the street is a steam-engine-operated 17-cu. ft. concrete mixer (Fig. 1) which dumps directly into a chute leading to the forms for the arch sewer. Steam is furnished by the same portable boiler which supplies the piledrivers. About 30 laborers are engaged in the concrete work and two masons on the brick invert. The

Fig. 2. Traveling Steel Trestle for Trenching Machine

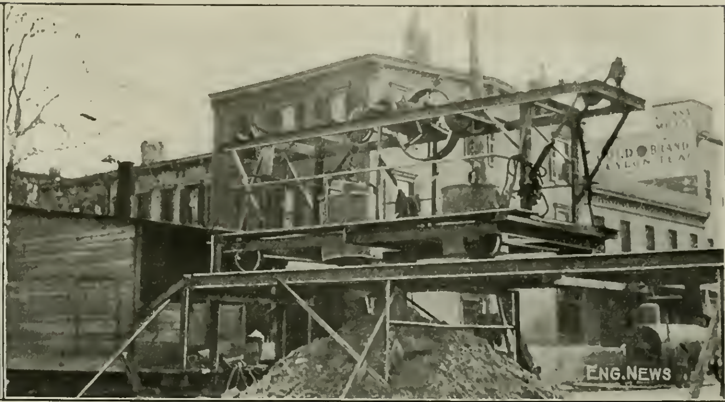

Fig. 3. Potter Sewer-Trenching Machine, Tompkins Ave. Sewer, Brooklyn, N. Y.

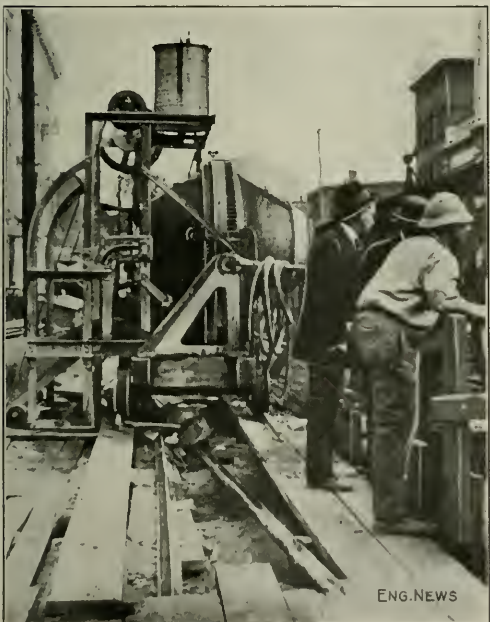

Fig. 4. Traveling Concrete Mixer, Tompkins Ave. Sewer

concrete work is, of course, so gaged as to keep pace with the excavation, and *vice versa*.

As soon as the concrete is sufficiently set, the backfill is continued over it. The bracing and sheeting remain in, and the street surface restored to use. About 100 men form the whole force engaged.

The contractor, John J. Creem Co., of Brooklyn, N. Y., has three such outfits on the same sewer contract, working independently on different sections of the work, which is under the supervision of E. J. Fort, Chief Engineer of the Bureau of Sewers, of Brooklyn.

The Removal of the Old Jackson St. Bridge at Chicago

The superstructure of the old Jackson St. bridge over the Chicago River at Chicago was removed in very short time, in May last, by cutting it apart with blowpipes and swinging the several parts onto barges by means of a derrick boat with 60-ft. steel boom.

The old bridge (built in 1888) had a three-truss swing span (with through trusses) 280 ft. long and 58 ft. wide, the east arm of which spanned the navigable channel of the river. The west arm spanned team driveways and freight tracks, beneath which was a bypass to give the necessary flow capacity to the river. The removal of this bypass, to make room for the new bridge, was described in our issue of Aug. 28, 1913, this bridge being built to give a greater width of channel, as required by the U. S. Government.

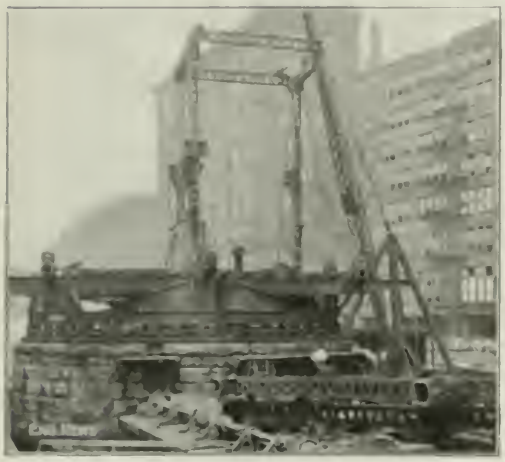
The new west abutment is close to the west side of the old center pier, and work has been commenced on the foundation for this. The coffer-dam has a single row of steel sheet piling, with heavy timber bracing. The weight of the adjacent pier and swing span, and that of the west retaining wall of the bypass, made it impossible to maintain this coffer-dam water-tight when excavating within it, particularly for the open wells which are to be sunk to rock for cylinder piers supporting the abutment. Therefore, it was considered better to remove the old bridge at once rather than to reinforce the coffer-dam at considerable expense.

Careful investigation showed that two high brick buildings on the east side of the river at Jackson St., built on pile foundations, must be placed on piers resting on the bedrock before it would be safe to put in the east abutment. The delay on the contract due to the construction of these piers under the buildings threw the removal of the old superstructure of the bridge into the season of navigation, while according to the contract and the arrangements originally planned, this span was to be removed in the winter time.

The cutting was to have been done with the Great Lakes Dredge & Dock Co.'s floating electric welding plant, which is provided with electric arcs for cutting a

well as welding, but at times the bridge superstructure had to be taken down (May, 1914), this plant could not be spared from its regular repair work on the fleet of dredges, tugs, etc., in the Chicago harbor. So it was decided to do the cutting with blowpipes, as it was important to avoid all possible delays to navigation at this season of the year on the busy Chicago River. The current at the bridge channel is about three miles per hour.

The bridge (weighing about 800 tons) was swung to the open position, and the floating turn up. The stringers were first cut away with the blowpipes, after which the floorbeams were cut loose in the same way. As the floorbeams were removed, the chords and diagonals were cut near the panel points, and the several sections swung onto barges by the derrick boat. Work was done from both ends so as to keep the remaining part of the structure in balance, as no falsework was used, and it was



REMOVAL OF THE JACKSON ST. BRIDGE AT CHICAGO, BY CUTTING THE MEMBERS APART WITH BLOWPIPES

necessary to maintain a nice poise as the truss action of the remaining members was much impaired.

The accompanying cut shows one of the top-chord sections of the center panel of a side truss being held by the derrick boom while a man is cutting it loose at the farther end with a blowpipe. The view shows also the severed portions of the three bottom chords, with one of the plate-girder floorbeams resting on the turntable. The small cabin in line with the center truss is the operator's house, the bridge having been operated by electricity.

The girders and members were cut mainly to 18-ft. lengths for removal, and will be cut with blowpipes to 3-ft. lengths for charging in furnaces as scrap. The thickness of the members cut varied from $\frac{3}{4}$ in. to 3 in., and where parts overlapped the thickness was as much as 6 in. Different types of blowpipes were used (the Oxweld, the Davis-Bournonville, the Engineering Sales Co. and the American Boiler Welding Co.), but most of the work was done with those of the Oxweld Acetylene Co. Not more than five operators were engaged in cutting with blowpipes at one time. The entire work occupied 15 days, including the removal of the turntable, leaving the masonry piers bare. It is believed that the acetylene torch or burner has some advantages over the electric arc in cutting steelwork, in that it cuts a narrower groove and is more easily manipulated than the latter.

In regard to removal by other methods it is stated that it would have taken at least four weeks to cut off rivet heads, drive out rivets, and chip or cut the members into the necessary lengths. In this case also there would have been required a greater amount of equipment in the way of air compressors, air hammers and chisels, and other tools, and probably falsework, together with more laborers and operators, while there would have been a greater amount of work in handling the parts by the derrick boat. The method employed effected a great saving of time and the delays to navigation were reduced to a minimum, this being an important item.

The new bridge will be a double-leaf trunnion bascule structure of the Strauss type, with deck trusses, having a span of 202 ft. $3\frac{1}{4}$ in. c. to c. of trunnions and 182 ft. c. to c. of front bearings, while the clear width of channel will be 168 ft. The bridge will have a 37-ft. roadway and two 13-ft. sidewalks. The substructure will include two masonry abutments, each supported on four concrete piers sunk to rock at a depth of 90 ft. below datum. The contract for the superstructure was let to the Strobel Steel Construction Co., and the contract for the substructure was let to the Great Lakes Dredge & Dock Co., both of Chicago. The substructure contract included the removal of the old superstructure (as described above) and the old substructure.

Some Neglected Points in the Theory and Adjustment of the Wye-Level

By J. A. Kitts*

Although the wye-level was invented 174 years ago (by Jonathan Sissons, of London), the writer does not believe that this instrument is generally understood, particularly in the method of use, by young engineers.

Two general methods of setting up a wye-level are used, one consisting of bringing the bubble to the center of the tube, and the other of bringing the vertical axis into a vertical position. The writer believes this latter method to be the proper one, and adjustments to suit this method are outlined herein. The former method is the more common practice; there seems to have been little said or written about the latter method, and it is the first impulse of the novice with spirit-level instruments to center the bubble, little understanding why he does so.

This practice of keeping the bubble in the center of the tube leads to error, as in the best of instruments the grinding or calibration of the bubble tube is such that the bubble centers differently for different temperatures; and the relation between the line of sight and the bubble position is therefore not amenable to fine adjustment.

The levelman centering the bubble for every observation at a different angle has no way of detecting the change of the relation between the tangential axis of the bubble tube and the line of sight, until the instrument is very badly out of adjustment. Unless he has time to

*Isthmian Canal [illegible], Panama.

check the adjustment often, here is another source of error. On the other hand, if the levelman levels so that his vertical axis is kept vertical, he becomes thoroughly acquainted with his instrument, knows where his bubble centers for varying lengths of the bubble due to atmospheric changes, and thus has an index to any changes in his instrument.

The wye-level was designed with the object of utilizing the principle of reversion to adjust the line of sight perpendicular to the vertical axis, and, by keeping the vertical axis vertical, maintaining the line of sight in a horizontal plane. In a completely adjusted wye-level the line of sight is necessarily perpendicular to the vertical axis of the instrument, and for successful operation the vertical axis should be kept vertical (operation 2, as given below), and it is not essential that the bubble rest in the center of the tube.

Keeping the vertical axis vertical is easily accomplished by use of the leveling screws in bringing the bubble into a position where it will remain for any angle of the telescope about the vertical axis. This does not depend upon the bubble axis being adjusted parallel to the line of sight but does depend upon the spindle and bearing fitting properly and not being worn elliptical in section. This provides an index to a defect in the spindle.

The line of sight can be adjusted perpendicular to the vertical axis (operation *3ab*) with fine accuracy depending upon the telescope collars being true circles of the same diameter. This is an index to a defect in the collars; (*3a*) and (1) cannot be accomplished if the collars are not of the same size and circular.

In a theoretically perfect wye-level the following specifications obtain:

(*a*) The object and eye glasses are perpendicular to the optical axis.

(*b*) The optical axis coincides with the axis of rotation in the wyes.

(*c*) The line of sight coincides with the axis of rotation.

(*d*) The line of sight is parallel to the tangential axis of the bubble tube.

(*e*) The collars resting in the wyes are true circles of equal diameter and concentric with the line of sight.

(*f*) The wyes fit either collar in exactly the same manner.

(*g*) The bubble moves over equal spaces for equal displacements of the telescope in vertical arc.

(*h*) The bubble expands or contracts equally from the center in both directions in changes of temperature.

(*i*) The vertical axis is perpendicular to the line of sight, or horizontal axis of the telescope.

The maker of the better class of instruments meets these specifications with a fine degree of precision, excepting in simple bubble tubes, specification (*h*), and, as been pointed out, this is not essential if the proper method of leveling the instrument is used.

Items (*d*) and (*i*) often require readjustment in the field, and the following procedure is suggested:

Wye-Level Adjustments and Use

(1) Make line of sight coincide with axis of telescope collars:

Clean collars and wyes. Level sight at point and clamp vertical axis. Revolve telescope 180° in wyes. Note vertical and horizontal displacement from the point. This is twice the error. Adjust cross-hairs and repeat until they remain on the point through 360°. Clamp telescope in normal position, unclamp vertical axis, and see that point follows horizontal hair when turning instrument about vertical axis.

(2) Make the vertical axis vertical:

Level over both screws, bringing the bubble to the center. Note end of bubble nearest the eyepiece. Rotate instrument 180° about the vertical axis and again note eyepiece end of bubble. Correct one-half the interval over both pairs of screws. The bubble will then remain in the same position for any angle of the telescope about the vertical axis and the vertical axis is then vertical.

(3) Make horizontal axis of telescope perpendicular to vertical axis:

(*a*) Keep vertical axis vertical by (2), having clips loose. Reverse telescope in wyes and again note end of bubble toward eyepiece. Adjust wyes to correct one-half the interval. The bubble then assumes a new position for (2).

(*b*) Check this adjustment by sighting on distant point, reversing telescope in wyes and again sighting on the point, keeping vertical axis vertical by (2). Adjust wyes for one-half the interval between sights.

(4) Bring bubble to center of tube:

(*a*) Make vertical axis vertical by (2). (*b*) Adjust bubble tube until bubble comes to center. Repeat *a* and *b* until bubble remains in center through 360° about the vertical axis.

(5) Bring bubble axis into vertical plane through axis of telescope: Level by (2) observing that bubble tube hangs in normal position under the telescope. Rotate the telescope slightly in the wyes, noting position of bubble for swings to right and left. If the bubble runs toward the eyepiece when swung to the right the end of the bubble tube toward the eyepiece is too much to the right, or *vice versa.*

(6) Repeat and check all adjustments as any one adjustment may affect another. However, this method of adjustment makes each adjustment as nearly independent as possible.

(7) In using level, level by (2) as calibration of bubble tube is usually such that bubble center is different for varying temperatures. The vertical axis should be kept vertical, as the line of sight is adjusted perpendicular to the vertical axis thus obviating releveling when taking observations at various angles, and thereby effecting an economy of time and labor.

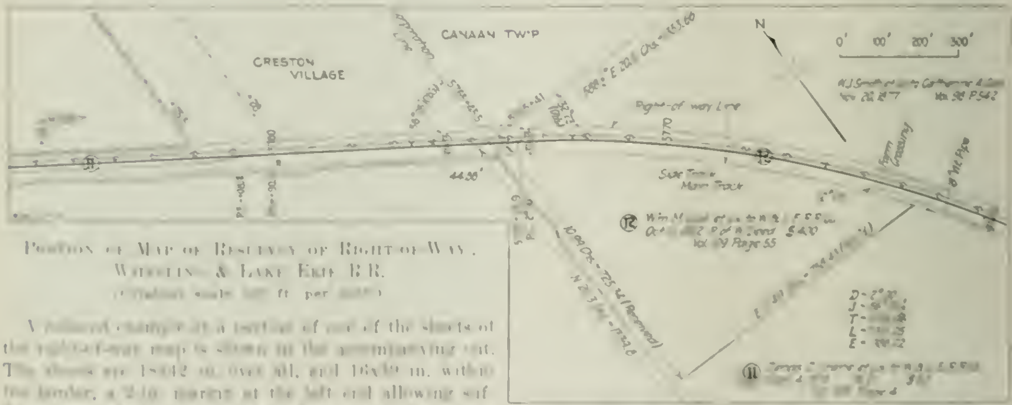
(8) Make line of sight coincide with optical axis: This adjustment is seldom necessary. If a distant object appears to shift position with reference to the aperture when revolving the telescope in the wyes, center the eyepiece until no movement is observed.

Making Permanent Record Maps Instead of Field Notes—To bring the records of street subsurface structures uptodate, one man experienced in field surveys and drafting work was assigned from each highway district office in Philadelphia, Penn., in 1913. The use of field books was discontinued. The note-books were replaced by 8½x11-in. sketch cards. These cards are used in the field for the plotting of the subsurface structures, etc., and are then forwarded to the office where they are properly colored and inked in by the drafting force, thus making these cards the office record, which does away with the work formerly involved in plotting the field notes from the book to the office card record.—From 1913 Report of the Philadelphia Bureau of Highways.

Resurvey of Right-of-Way: Wheeling & Lake Erie R.R.

A class of work which has been undertaken by several railways in recent years is that of resurveying and marking the right-of-way and other land owned, in order to have exact location and record of such property. The importance of such work is readily appreciated when it is realized that original records are often incomplete or faulty. As property both in the cities and along the railways increases in value it is increasingly necessary for the railways to define and assert their ownership by setting fences and monuments and recording all deeds and other transactions as to real estate.

Work of this kind has been carried out on the Wheeling & Lake Erie R.R., under the direction of W. L. Rohbock, Chief Engineer. The work of making the surveys and preparing the right-of-way maps covered a period of about five years for the entire system, involving about [illegible] miles of main line and branches. The cost of this, including all survey work and drafting, was about $60 per mile.



Portion of Map of Resurvey of Right-of-Way, Wheeling & Lake Erie R.R.
(Original scale [illegible] ft. per inch.)

A reduced example of a portion of one of the sheets of the right-of-way map is shown in the accompanying cut. The sheets are 18x42 in. over all, and 16x40 in. within the border, a 2-in. margin at the left end allowing sufficient room for binding. These plans are all made on a scale of 1 in. to 100 ft., except that the extra sheets showing the right-of-way through thickly settled cities or villages are on a scale of 1 in. to 50 ft.

On the drawings, the original center line as relocated by surveys is shown in a full red line, and the main track, where not coincident with this center line, is shown in black. Where the track is on or near the center line, only the rail line is shown. All company additions, private tracks, street lines and outlines of allotments are shown in full black lines. Switch lines and figures representing the [illegible] (as taken from recorded maps) are shown in blue. Measured distances and figures representing [illegible] dimensions given in deeds, etc., are shown in black. The outline of the railway company's property is shown by broken lines (dash and double dot); fences are shown by broken lines, with [illegible].

Figures enclosed in circles designate the various parcels of land referred to in the property title notes on each sheet. Monument figures are shown in red. Points where iron rod monuments are set are shown by red spots. Different tints indicate ownership as follows: (1) land acquired by deed, right-of-way contract or agreement; (2) land acquired by condemnation or act of public official; (3) land acquired by lease; (4) land held in trust by agents or trust company; (5) land sold, or leased indefinitely. The explanation of this coloring scheme is shown on each sheet.

On account of the stationing on the road starting from the west end (at Toledo) and running toward the east, the maps are all made to read from left to right. Reference to this stationing is made along the right-of-way, being shown in white paint at intervals in conspicuous places such as telegraph poles, station buildings, etc., where the stationing may be easily picked up should it become necessary to tie into it when making additional surveys.

The original center line of the right-of-way is shown in all instances and where it does not coincide with the center line of the present track both the original center line and the track center line are shown. The fences along the right-of-way are not shown except where they do not coincide with the established right-of-way lines. Right-of-way posts are set at places where fences would not be desirable. These posts are 6 ft. long and project 3 ft. above the ground, the portion projecting out of the ground being turned to a diameter of about 6 in. The post is painted white and the lettering runs perpendicularly, showing it to be a right-of-way post of the W. & L. E. R.R.

One of the handy features of these maps lies in the references given to the original purchase of right-of-way. These are numbered consecutively through the different counties, the right-of-way lands being divided into the several different counties along the line. The references show the date of the original purchase, the name of the original owner, price paid for the right of way and general conditions of the purchase. On sheets involving considerable detail as to streets and other data, where these references cannot be shown, the number of the reference is simply shown on the parcel and a separate sheet is made up giving the details as above described. Examples of these references on the maps are as follows:

8. W. & L. E. R.R. Co. to N. Y. P. & O. R.R. Co. Apr. [illegible], 1886. Lease. [illegible] Lease for term of 99 years and renewable forever on similar terms without further [illegible]. To be used for railway purposes only. W. & L. E. R.R. Co. to defend the N. Y. P. & O. R.R.

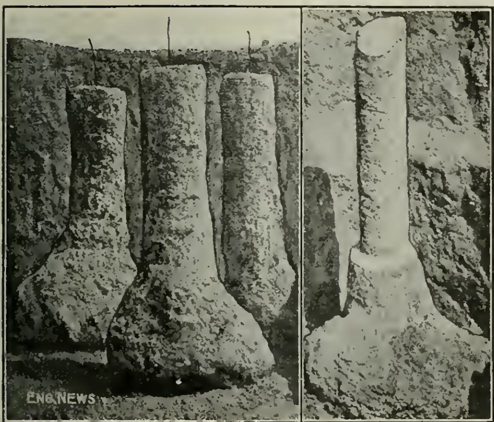
Co. in the enjoyment and peaceable possession of the premises. Part shaded in (green)covered by this lease.

10. A. L. Miner to W. & L. E. R.R. Co. Mar. 3, 1874. Right-of-way contract and $300 in company stock. Lease. Record, Vol. 1, page 577-8. A. L. Miner agrees to convey land if railway is built not later than two years from this date. Also railway company to have enough land in addition to the 66-ft. strip named to maintain proper slopes, and after location of said road the railway company may cut down trees that are liable to interfere.

12. Wm. M. Cook et ux. to W. & L. E. R.R. Co., Oct. 11, 1882. Right-of-way deed. $400. Vol. 109, page 55.

Concrete Piles with Bulbous Ends Formed by Explosive

The formation of enlarged or bulbous ends for concrete piles cast in place, in order to serve as footings and give increased bearing, has been employed in a number of cases, and a process of forming the cavity for the bulbous end by means of explosives has been invented in



Concrete Piles with Enlarged Bases Formed by Exploding Charges at the Bottom of the Holes

Europe, which is known as the Wilhelmi system. A wooden pile inclosed in a 16 or 20-in. steel tube is first driven, and is then withdrawn, leaving the tube in place. The explosive charge is then lowered in a shell or casing so made that the force of the explosion will be directed mainly in a lateral direction. The hole is then partly filled with concrete and the tube drawn up about 1 ft., after which the charge is fired and the wet concrete settles into the cavity thus formed. Fresh concrete is at once deposited until the hole is filled, the tube being drawn up at the same time.

This process has been used for supporting the pivot of a locomotive turntable at Havre, France, the foundation being a circular block of reinforced-concrete 15 in. diameter and 16 in. thick, supported by a single central pile 16 in. diameter. The point of the wood pile penetrated to a depth of 22½ ft. and the bottom of the steel tube to 21½ ft. A charge of about 1 lb. of explosive was placed and the hole filled for about 16 ft. with concrete, which dropped nearly 13 ft. after the explosion. As the additional concrete was filled in and the tube withdrawn, the concrete was tamped with a 220-lb. ram, spreading it into the compressible earth. The enlarged head was loaded with 40 tons of rails which remained in place for three weeks without causing settlement.

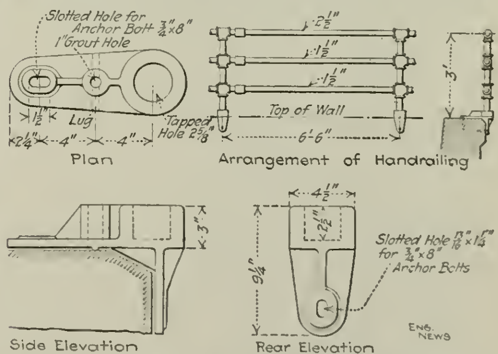
It is stated that in soft or loose soil the practice is to sink several piles close together. The French patents are owned by Camus, Besse & Drieux, of Havre, France. Our information is taken from an article in the June number of "The Railway Engineer," of London, from which also the accompanying illustration is taken. The same (or a similar) system, but under a different name, was noted in our issue of Aug. 21, 1913.

Hand-Railing for Bridges and Retaining-Walls

Where hand-railings are placed on railway bridges and retaining-walls it is desirable to place them near the outer edge of the bridge or wall, in order to give as much clearance as possible between cars and the railings. In some cases the railings are inclined outward to enable a man to lean back out of the way of a passing train.

On concrete walls and parapets it is very general practice to set the posts or standards of the railing at approximately the center line, but in the track-elevation work at Memphis, Tenn., the railings are placed along the outer edges of the retaining-walls and the shallow curb or parapet walls of the bridges. This is done by means of angle-shaped sockets fitted to the edges of the wall, as shown in the accompanying cut. This cut represents the railing on the South Front St. subway of the Illinois Central R.R.; in some other cases the posts or standards are 6 ft. apart.

The socket has a threaded hole for the pipe standard, a grouting hole, and two holes for anchor bolts, while a rib across the bottom leaves a ¼-in. grouting space between the casting and the masonry. The top of the railing is lined up to a straight line by rocking the castings on these lugs and tightening and loosening the bolts as



Hand Railing Set on Edge of Retaining-Walls on Track Elevation Work at Memphis, Tenn.

required. When the railing is in line, the castings are grouted to a permanent bearing. The anchor bolts are leaded in place.

A Gyroscopic Monotrack Automobile has recently been demonstrated in London. This car has two wheels placed centrally in line in the chassis, while in the center of the chassis, below the seat, is the gyroscope, which is electrically driven. The speed of the gyroscope is 1200 r.p.m.

An Ash Wagon with Electric Hoist

For removing ashes from isolated power plants the Union Electric Light & Power Co., of St. Louis, Mo., operates ash wagons equipped with electric hoists to raise the ash buckets through manholes in the sidewalks. During the winter about six teams are in service, each hauling five loads daily. One of these wagons is shown in the accompanying cut.

Ash Wagon with Electric Hoist

The hoisting apparatus consists of a ½-hp. motor driving a small drum. The motor runs continuously and is connected to the drum by a loose belt, there being a belt tightener which is operated by hand when it is desired to hoist the bucket. Power is obtained through an extension cord connected to a lamp socket in the buildings. The motor, starting box, drum and belt tightener are all assembled on an iron bedplate supported by four spiral springs, and located at the rear of the wagon, as shown. There is also a davit fastened to the side of the wagon, with a pulley extending over the sidewalk to drop the bucket through the hole to the basement.

One man on the wagon operates the hoist and handles the bucket, another man being below for loading the buckets. A light wire rope is used for hoisting. The buckets are small, being only about 16-in. diameter, this being necessary on account of the small holes in the sidewalk. For information as to these wagons we are indebted to John Hunter, Chief Engineer of Power Plants of the above company.

Organization for Surfacing Track*

Prior to a job of surfacing track the first thing to consider is the widening of banks where the subgrade is too narrow to hold the ballast. The widening can be done to advantage with material excavated in widening cuts. The next thing is to decide on the uniform raise to be given the track, and the raise to be made in sags (if any). This being settled, the engineer should mark the grade stakes (in vertical figures) near the top to show the raise in inches. The figures should be on both sides (and not on the face), so that the conductor of a gravel train from either direction can see the figures. The station number can be marked on the back of the stake. This arrangement will assist the roadmaster and work-train conductor in getting the material distributed properly.

When track is to be raised more than 12 in., one short lift should be taken care of first, and the track given one lift with the first lot of ballast to make room for sufficient material to finish surfacing on the second lift. Doing this work first avoids the necessity of hauling gravel over track where the surfacing crew is at work. The unloading and distributing of gravel should be under the personal direction of the roadmaster or an experienced foreman, and not left entirely to the work-train conductor. In this way the work can be supervised and markers set up to indicate where additional material is to be deposited by the next train.

I recommend the following organization for surfacing gangs varying from 50 to 100 men: One foreman, two assistant foremen and one timekeeper. One assistant foreman to do the raising, and the other to do the lining or to herd the men who are doing the tamping, as the work may require. The crew should be provided with six track jacks, two level boards, and two spot boards. One man should have charge of setting up the spot boards. A sufficient number of men should be kept ahead to dig jack holes, which should always be dug level so as to guard against throwing the track out of line.

When raising track with 100 men, four jacks should be used (two on each side), and both sides raised at the same time. No men should be allowed to work ahead of the man who is sighting the track, so as not to interfere with his work in sighting the spot boards.

Wherever there are grades, the work should progress against the grade if possible. This will assist materially in holding the steel from running down grade. The foreman should see that the assistant foreman doing the raising makes a good run-off at the close of each day, so that it will not be necessary for trains to reduce speed at night. For eight gangs of tampers, two on each side and four in the center, the foreman should pick out eight of his best men and make these the leaders. Two tampers on each side and four in the center should go ahead, and tamp one tie and skip three ties and so on all day. The second and third gangs will tamp the next ties, and the fourth gang tamps the fourth tie, thus finishing the tamping in full. The center tampers do the same as the outside tampers, thus finishing up as they move along in organized form. The number of gangs may be reduced to three or increased to five, according to requirements.

*Condensed from an article on the "Track Foreman" [illegible] of the Roadmasters' and Maintenance of Way Association, by [illegible], Division Roadmaster, Minneapolis, St. Paul & Sault Ste. Marie Ry., Minneapolis, Minn.

Instruction Diagram for Trackmen on a Chinese Railway

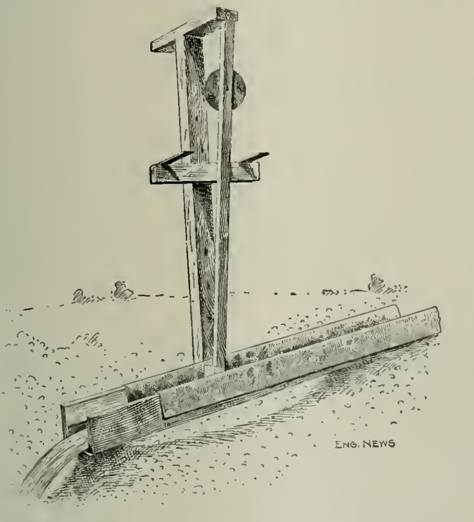
An example of the instruction diagrams issued to Chinese section foremen on the Shanghai & Nanking Ry. is shown in the accompanying cut. It indicates that in handling material on a push car there must be a

red flag on the car, while other red flags are to be carried at a distance of 15 rail lengths in advance and in rear of the car. The foreman must stay near the car. Any infringement of the regulations "will be met by severe punishment." The cut is reproduced from an article in *The Engineer*, of London, May 22.

The railway is 193 miles long, with a 10-mile branch to Woosung, and is double-track for 54 miles. The track is laid with 36-ft. 85-lb. T-rails of the British standard section; the ties are of jarrah wood, 10x5 in., 9 ft. long, with 14 ties to a 36-ft. rail length. The line is well ballasted throughout. There is one tunnel 1320 ft. long built for a double line 28 ft. 3 in. wide at spring of arch and 27 ft. 3 in. at rail level, the height being 21 ft. 3 in. from rail to soffit. The line was opened in 1908. A. C. Clear is Resident Engineer.

A Field-made Pendulum to Indicate Pump Discharge

The accompanying illustration is from a photograph taken on one of the contracts of the Passaic Valley Sewer near Newark, N. J. It shows how a light 1x2-in. stick suspended from a frame as a pendulum, with its lower



Field-Made Pendulum to Indicate Pump Discharge

end in the flume of a pump discharge, indicates by its oscillation how the pump is working.

A steam vacuum pump is used to keep the water out of the excavation, discharging through about 150 ft. of rough wooden flume. About 30 ft. from the end a gallows-frame of 2x6-in. and 2x4-in. timber, about 6 ft. high, is erected at one side of the flume. From the head of this frame, hanging by a screw-eye over a nail, is a 1x2-in. stick about 6 ft. long. At the bottom of the stick a piece of rubber belting is nailed to form a paddle and to offer a larger surface to the stream of water. A round sheet of tin, about 8 in. in diameter and cut out of the top of a tin can, is nailed to the stick to form a target, and a little horizontal piece is attached to the standard about halfway up to form a guide so that the pendulum will not swing too far out of line.

The surge of the stream not only keeps the pendulum at an angle but continually agitates it through an arc of 10 deg. or 15 deg. By glancing at the indicator, the foreman, several hundred feet away, can always tell approximately how the pump is operating.

Instructions to Civil Engineers of the Southern Pacific Co.

For the benefit of the hundreds of young men just starting their careers as railway civil engineers, and for other engineers who wish to have a little insight into the duties of railway field engineers, we reprint the newly revised instructions of William Hood, Chief Engineer of the Southern Pacific Co., to chiefs of party and transitmen:

INSTRUCTIONS TO ENGINEERS IN CHARGE OF FIELD PARTIES

(1) All pay-rolls and vouchers are to be made out on the first day of each month, on the blanks furnished for that purpose, and forwarded to the Chief Engineer.

Give the Christian name and initial letter of a middle name on payment roll and voucher.

Itemize all vouchers, giving the date and place of disbursement; and when possible to do so, take receipt for all disbursements.

Time will be computed by calendar months and fractions of the same. A contribution of 50c. per month for hospital department will be collected by deduction on pay-roll from all officers and employees of the company, with the exception of Chinese, and those specially excluded from benefits. This contribution will be due on entering the company's service, and thereafter will be due for and apply to each month, or part of a month, while in the service.

(2) No time will be allowed men absent on private business. No time will be allowed any of the party, excepting those placed on duty by the chief of party until the work for which they were engaged shall commence; nor will any time be allowed after the evening of the last day's work, excepting to those detailed as teamsters, cooks, or for other duty by the chief of party or his agent. Give to men discharged a certificate of the time and amount due them.

(3) All men will be returned free to the place at which they were engaged for any particular survey—excepting by agreement to the contrary—unless discharged for disobedience or incompetency, or leaving without the full consent of the chief of party, in which case traveling expenses will not be allowed. Ten days' notice will be required from all employees, in order to leave the service in good standing, unless the requirement be waived by the engineer in charge.

In case of sickness of any member of party entitled to hospital treatment, the chief of party must give a hospital certificate.

(4) Books, stationery, instruments and other property of the company are to be kept in good order; the chief of the party will be charged for the same, and he must return them in like order in which they were received, or satisfactorily account for their damage or loss.

(5) All requisitions must be sent to the Chief Engineer by letter and the telegraph is not to be used for that purpose, unless writing would occasion delay or loss.

(6) Note on first page of every field book a full description of the particular route, line and work to which the notes relate, and enter date of each day's work in the proper place.

(7) Note name and address in each transit book of all members of the party; and in the level book, name and address of leveler and rodman.

(8) A journal must be kept, fully describing each day's work, and noting all information of interest, and how it was derived.

(9) Monthly reports must be sent to the Chief Engineer on the first day of each month, giving the lengths and descriptions of the various lines run and all work done, with such other information as may come within the knowledge of the engineer in charge, of which the Chief Engineer should be informed.

INSTRUCTIONS TO TRANSITMEN

(1) See that transit plummet and line are well protected from air currents, while being adjusted to the angle point.

(2) No instrument station must be in such a position as to prevent the line of sights for backsights or foresights striking within 2 in. or less of the point of the rod.

(3) Double-center all instrument points, checking each sight back, after setting the point on foresight.

(4) No sights are allowed longer than 1000 ft. on tangents, or 800 ft., or 45° deflection, on curves.

(5) On taper curves, the B.C. or E.C. and C.C.'s of main curve must be put in from each other by one deflection and long chord, and not through the intermediate compound curve points.

(6) [illegible] all angles [illegible] bearings of all courses and take [illegible] at least once in ten miles [illegible], [illegible] country, and once in 25 to [illegible] [illegible].

(7) A [illegible] of [illegible] notes will be made out each evening on a tracing sheet, showing true (or assumed) bearings, and magnetic bearings for use in mapping and for ready detection of errors [illegible].

(8) All lines in [illegible] country will be run with a [illegible]-ft. chain. In open country a 100-ft. chain may be used on the tangents, and a [illegible]-ft. chain on all curves.

(9) On location lines small pegs must be driven to the ground surface at each chain length as well as the usual [illegible]. On [illegible] lines stakes only need be used, except at instrument points.

(10) Stakes must be well driven and fit to stand several years.

(11) Chainmen will use hand levels to determine the difference of height of the ends of the chain, and will use [illegible] on all rough ground. Chain must be stretched out [illegible] in line on rough ground, before measuring the short [illegible] distances, so as to use all parts of the chain instead of using one part repeatedly.

(12) All instrument stations put in at other points than at end of full chain must be measured in with steel tape and checked by chain. Where an instrument station is set at other point than at end of full chain the next full chain station must be [illegible] from the last one back of the instrument and not from the instrument point.

(13) Chain must be tested once a day at least.

(14) All transit books must be paged and fully indexed.

WILLIAM HOOD,
Chief Engineer.

A Hand-Power Piledriver

The piledriver shown in the accompanying sketch is one built by the Chicago Tunnel Co. It was used at work at 12th St. and Wabash Ave., Chicago, to drive 4-in. pipe down 45 ft. to meet the section of the tunnel in service under 12th St. While this driver was designed to drive pipe, there is no reason why it should not operate successfully on light sheet piling.

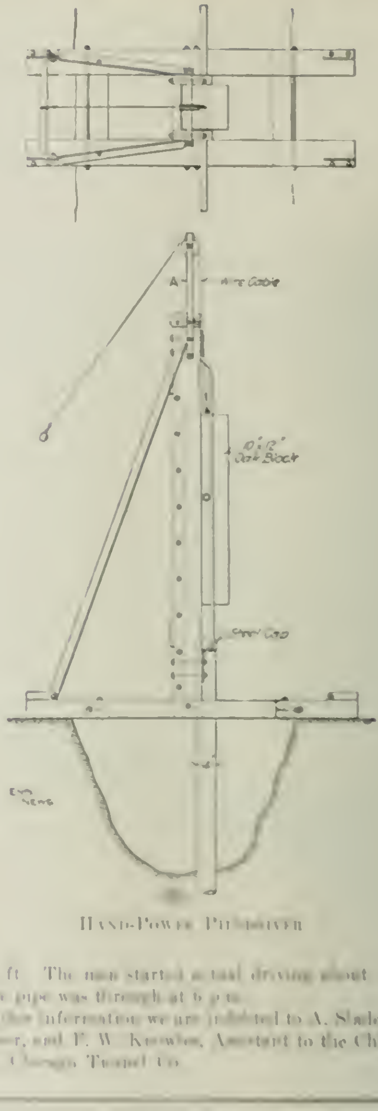
The driver itself consists essentially of a channel lead A, built by bolting two 2x6-in. sticks to each edge of a 2x12. This lead, about 6 ft. high, is supported vertically on a pair of heavy horizontal skids, approximately 4x6 in., and is braced back on to the horizontal skids by a pair of steel angles. The actual driving is effected by a 10x12-in. oak block, 12 in. long, sliding in the lead.

The driver is operated by four men; two stand behind the driver and with a pick handle looped into a cable, raise the block; the other two, standing each side of the block, working with a piece of pipe put through a hole in the block, bring the block down on the pipe being driven. The [illegible] effort of each pair causes the rig to deliver about [illegible] blows per minute.

To keep the block from going outward, a pair of guides are fastened to the face of the lead. The pipe-handle slides inside the guides.

On the work in question, 4-in. pipe was being driven [illegible] ft. [illegible]. A [illegible] cap screwed into the end of the pipe took the impact of the blows. Short sections, [illegible] ft. long, and [illegible] blocks were used to get the pipe down. [illegible] of driving is shown by the fact that on this work [illegible] ft. of [illegible] pipe was driven down so as to [illegible] a [illegible]-in. opening [illegible] in the roof of the tunnel.

The daily cost of operating on this particular job, comprising the team of four men at $[illegible] each and one foreman at $[illegible], working 10 hr. Only one day was needed to get the pipe down. This included taking up a [illegible] [illegible] over an area of about [illegible] ft., and excavating a hole about [illegible] ft. deep, with an average cross-section of [illegible] ft. The men started actual driving about 11 a.m. and the pipe was through at [illegible] p.m.



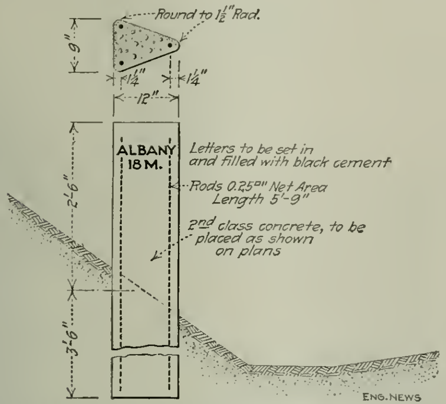
HAND-POWER PILEDRIVER

For this information we are indebted to A. Slade, Chief Engineer, and F. W. Knowles, Assistant to the Chief Engineer, Chicago Tunnel Co.

NOTES

Calculation of End Areas for Earthwork—[illegible] [illegible] calls our attention to the fact that substantially the same method of computing end areas as that described by W. L. Webb in our issue of June 11, p. [illegible] was proposed by him in "Engineering News," [illegible]. [illegible] we find this to be so, but Mr. Webb has described the process in more detail, and shows how the method may be applied to end three-section [illegible]. Originality for methods of earthwork calculation is a difficult claim to prove, as any one may determine for himself if he will look through the files of "Engineering News" for the past 10 or 15 years. For no matter how much original research one puts into this subject the subject itself has been explored so thoroughly that there is hardly a possibility of finding a single [illegible] of [illegible] growth in the whole field.

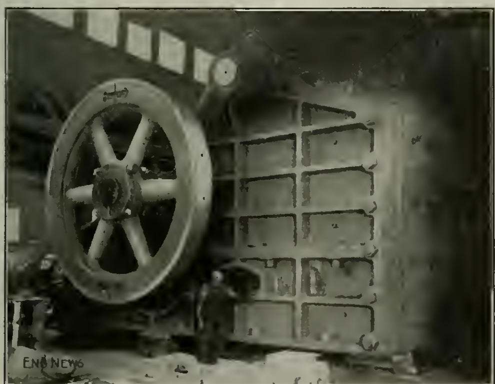
Reinforced-Concrete Mile Post—The accompanying illustration shows the standard reinforced-concrete mile post adopted by the New York State Highway Department. Each post contains about 1½ cu.ft. of concrete, so taking the cost of concrete at $10 per cu.yd. we have $0.55 per post, as an approximate estimate of the cost, exclusive of the rods and of the inscription.



STANDARD CONCRETE MILE POST, NEW YORK STATE HIGHWAYS

Very Large Rock Crusher—The accompanying view shows an all-steel frame jaw rock crusher with a 60x84-in. opening for breaking up rock to be used in the manufacture of asbestos.

The side plates are of rib design and were cast in two parts. The end plates are one piece. The crusher will be 19 ft. 7½ in. long, 11 ft. high and 18 ft. 1½ in. wide, and will weigh 500,000 lb. The machine is made of cast steel throughout, with manganese-steel crushing plates, check plates and toggle seats. A better idea of the size of some of the working parts can be obtained perhaps from their dimensions, notably those of the shafts. The main shaft is 23 in. in diameter, and the swing-jaw shaft 19 in.



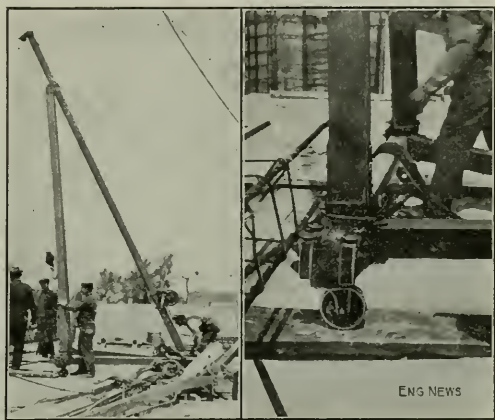
A 60x84-IN., ALL-STEEL FRAME JAW ROCK CRUSHER

What was primarily here desired was ample size of opening, in order to permit a reduction in quarrying expense. The size of the feed opening is 60x84 in., and under working conditions the crusher will deliver a 10-in. product. As an indication of its capacity, when crushing down to 14 in., it will crush approximately 1000 tons per hour. When crushing to 10 in., its capacity with asbestos rock is expected to be 3000 tons per 8-hr. day.

This crusher was built by the Traylor Engineering & Manufacturing Co., Allentown, Penn., for the Asbestos, Que., plant of the H. W. Johns-Manville Co., and cost about $25,000.

A Portable Cantilever A Frame Derrick—Handling construction units in concrete work is an interesting problem. Reinforcing rods are fabricated into bulky units, more or less rigid (usually less), and these frames have to be placed in the form; the "how" is often hard to find, at least with due regard to low cost.

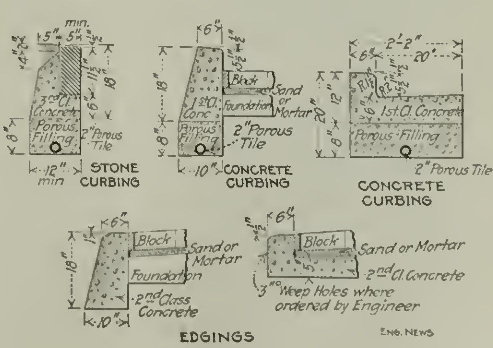
On work for the Excelsior Motor Co., Wells Brothers, Chicago contractors, built a cantilever tripod derrick rolling on heavy truck-casters and equipped with a hand winch. The frame was made of 6x6 timbers. The base is an equilateral triangle some 8 ft. on a side. The head block is about 20 ft. above the floor level. This derrick, set on plank runs laid on the floor forms, was used for elevating and placing fabricated frames of steel reinforcement in the heavy wall panels. Two views are shown herewith.



A PORTABLE CANTILEVER A-FRAME DERRICK

In Unloading Stone from Cars for the sewage filter at Aberdeen, S. D., the work was done mainly by rigging up a block and tackle so that a drag scraper could be pulled lengthwise of the car. The scraper dumped at the end over a trap into small dump cars below, on a 24-in. gage track. About 175 carloads of crushed stone were required to make the filter bed, and the above arrangement reduced the cost of unloading and making stone into position by about 50% as compared with unloading by hand. This statement is made in a paper by W. G. Potter in a paper on this sewage disposal plant, read recently before the Western Society of Engineers.

Curbings and Edgings, New York State Highways—The accompanying illustrations are self-explanatory. They represent the latest practice of the New York State Highway Department. Curbings are placed on roads through villages, where the street is bordered with sidewalks. The edgings are necessary on brick or block-paved roads.



First Aid for Derailed Dump Cars—In handling heavy excavation work with steam shovel and dump cars, the impact of the [illegible] if it hits the dump car off center is very apt to throw it off the track. To keep the work going properly, it is of [illegible] to keep cars on the track. On one of the contracts on the Sag [illegible] near Blue Island, Ill., where a [illegible] steam shovel is loading into 7 cu.yd. end dump cars which are pulled up an incline, the car tender keeps a short piece of cable ready to [illegible] at the loading point. At the first [illegible] when the car goes off the track, the tender jumps forward with the cable, gives it a sling around the front axle and a loop over the teeth of the dipper. A little signalling, [illegible] "wig-wagging," some nice handling of the heavy boom and dipper, and the car is easily and quickly put back on the track. The contractors on the work where this kink was noted are Byrne Bros., Chicago.

ratio between the strengths of the materials, that is, $\frac{s}{c} = \frac{16,000}{650} = 1:24.66$. Connect the ends of the lines as shown. Then the vertical distance from the top to the intersection of the lines is the depth to the neutral axis of the beam, in per cent. of d, the depth to the center of the steel.

LOOPING OF CABLE OVER DIPPER TEETH TO RESTORE DERAILED CAR

A STEAM-SHOVEL DIPPER BOOM FOR AIDING DERAILED DUMP CARS

A Spring-Roll Covering for a Drawing Table—The accompanying sketch shows the method employed for covering the drawing tables in the office of the Reinforced Concrete Co., St. Louis, Mo. Using a spring curtain roller is not especially novel; on the other hand, it is not universally in use in drafting rooms, although apparently the best method known. The novel feature of the present sketch is that the roll is mounted on a hinged board which can be swung back under the table and out of the way. Ordinary screen-door spring hinges are used. The bar in the end of the [illegible] [illegible] which holds the covering smooth and close against the drawing board, is usually of ½-in. round steel.

ARRANGEMENT OF SPRING ROLLER AND COVERING FOR COVERING DRAWING TABLES

A Graphical Determination of the Neutral Axis [illegible]

[illegible]

To find the percentage of steel: At b, Fig. 2, the shaded triangle is the total compression in the concrete, according to the straight-line formula. The maximum stress f_c is at the top and the area of the triangle $= \frac{f_c}{2} \times k$. The unit resisting moment $R_c = \frac{f_c}{2} \times k \times j$, in which j is the moment arm and is equal to $d - \frac{k}{3}$.

Then $R_c = \frac{f_c k j}{2} = 325 \times 0.38 \times 0.873 = 108$ (slide-rule used).

The steel ratio $p = \frac{R_c}{j f_s} = \frac{108}{0.873 \times 16,000} = 0.0077$

Editorials

Many strange tales have come out of East Aurora, New York—the home of Elbert Hubbard. Not the least strange and weird—to an engineer at least—is the following from the *Buffalo Express*:

East Aurora, June 23.—The problem of a sinking bridge is again before the village officers. Early this spring a new wooden bridge was built across a pond on the Gurdle Road, which leads directly through the quicksand beds in the northern section of the village. The new bridge has followed the trail of its predecessors, and is fast sinking into the pit that has already swallowed up 28 or 30 bridges in the last 50 years.

The sinking pond has a unique history. Originally, there was only a country sluice, with a four- or five-plank bridge to span it. Gradually it has increased in width, until now it takes nearly 300 ft. of planks to cross the black hole. The underlying formation is quicksand and the bridges slowly sink from sight. The new bridge, built less than three months ago, has been condemned by the highway commissioner, and the state department has been asked for a remedy to put a stop to the wholesale devouring of a bridge or two each season.

It seems to us that East Aurora displayed remarkable sagacity in turning to the State Department for advice. The recent experience of that department with treacherous quicksands should certainly have enriched it with a fund of experience to draw upon.

Engineers have some experience in dealing with ordinary quicksand, but a quicksand of such specific gravity that wooden structures and planks sink into it instead of floating on its surface is too diabolical and unprecedented for engineers to tackle. They will much prefer to have the experimenting on such quicksands done by diplomats. They may possibly be light enough to float.

Preventing Conflagrations by Rebuilding Congested Districts

The recent great fire in Salem teaches anew the same lesson which was taught by the conflagrations in Chelsea, in Baltimore and in half a dozen other cities during the past dozen years, to say nothing of the great Chicago fire. The lesson is that a large area of buildings of inflammable construction, closely huddled together, is a danger to other and more valuable sections of a city.

In certain foreign cities, the municipality itself has been empowered to tear down and rebuild whole areas, compensating the owners of private property for the damages; but we recall no case in which an American city has undertaken a similar sweeping reformation. In Cleveland, Ohio, however, through the fortunate circumstance of a railway condemning a considerable area for terminals, the city's most congested tenement district is to be partially abolished. The Cleveland & Youngstown Ry. Co., a new interurban line, has recently acquired property for terminals in this district and is tearing down over 130 buildings occupied by some 3000 persons.

When municipal authorities awake to the importance of city planning, such condemnation of districts which constitute a fire hazard to the rest of the city may become common. Under present laws, however, it would be exceedingly difficult for an American city to undertake such an enterprise.

The Approach Facilities of Large Railway Stations

A feature of railway station design which seems rarely to be given the attention its importance demands is that of the approach facilities for passengers. The track layout, the trainshed plan and the conveniences inside the station building are carefully studied. The architects lavish artistic ability on the ornamentation of the structure but the arrangement of street approaches with a view to the comfort and safety of arriving and departing passengers appears to be very largely neglected. A recent controversy between municipal and railway authorities over the plans for a new station was based largely upon complaint as to the inadequate and inconvenient passenger approaches provided by the plans.

Because of this usual neglect, especial interest attaches to the excellent solution of the problem at the Pittsburgh passenger terminal of the Pittsburgh & Lake Erie R.R., illustrated in this issue. Here a passenger arriving or departing is under cover all the way from the train to the street car, nor does he have to cross a street crowded with traffic in order to take a car going in the direction he desires. The way in which this is done is simple enough—merely roofing over a short section of the street, and making a subway beneath it; but it is none the less deserving of careful study. In this case the tracks are below the street level, but where they are elevated the street shelter may form a bridge connection with the train floor of the station.

It will be evident that in order to carry out this desirable improvement, coöperation between the railway, the city authorities and the street railway company was necessary. This coöperation ought in theory to be easily obtained. In practice it appears to be very difficult.

We have in mind one of the most costly and well planned suburban railway terminals in this country, completed only a year ago. It would have been perfectly easy to have arranged sidings at the station where street cars could have received the passengers delivered by incoming trains. Special cars for this purpose have long been required. The city authorities, however, would not permit street-car tracks to cross a sidewalk, hence one may see daily the entire traffic on the city's main street blockaded while a crowd of passengers are boarding the cars.

At many stations in this country the passenger who takes a cab or omnibus is well provided for and protected from the weather; but similar protection for the street-car passengers, many times as numerous as those who take cabs, is very seldom provided.

Nor is the covered cab stand always to be found. At how many stations may be seen cabs standing at the curb

with passengers landing on an open sidewalk and standing in the rain, snow, or wind while they pay the drivers and collect their baggage? At one several-million-dollar station may be seen thrifty porters who have equipped themselves with umbrellas to meet these conditions and to encourage the grateful tip.

Many railway stations in this country are placed as close as possible to the street, but in foreign cities it is very general practice to put a large court or open space between the street and the station, even when (as in London or Paris) the land thus occupied is of high value. This is due in part, no doubt, to the much larger proportion of cab traffic, which could not well be accommodated at the curb without interfering with the stream of street traffic. At the station entrance, therefore, the railway company may build such covers and shelters as it desires, without interference by municipal authorities. In many cases, also, the vehicles may drive into or through the train-shed. One objection to this has been the consequent dirt and smell, but with the reduction in horse-drawn vehicles and the increase in motor vehicles this objection is becoming of less weight.

Where a passenger must walk all the way across a broad plaza to reach a street car, the distance of the station from the street is an objection. The proper method in such cases is to locate loops or sidings for the street cars close to the station where they can take on passengers without stopping traffic on the main street.

Ocean Traffic and Municipal Prosperity

A great deal has been said and written in the last dozen years concerning the great effect which the opening of the Panama Canal is expected to have on the growth of various cities, particularly in the South. Most extravagant expectations are entertained as to the stimulus to trade and traffic which will result from the opening of the canal and the impetus to the growth of various commercial cities and seaports which will result. The fact is, however, that even if the canal should carry as great a volume of traffic from the very start as its most sanguine promoters have claimed, there is little reason to believe that it will have any noticeable effect on the growth in wealth or population of any city or seaport either on the Atlantic, Pacific or Gulf coasts.

The idea that the opening of the Panama Canal will greatly develop the commerce and wealth and population of various seacoast cities is really part and parcel of the widespread fallacy that commerce is the great influence which upbuilds cities. We refer to commerce, of course, in the limited sense of transportation, and in the broader sense in which the term includes all industry. It is not strange that this fallacy should be widespread, especially in commercial circles, but engineers who study causes and effects should have a juster view of the situation.

The reason why this fallacy is so widespread is because up to comparatively recent times it was indeed commerce which determined the growth of cities. It is a most interesting chapter in history that traces the rise and fall of famous cities in Europe by the growth and decay of their commerce. It was her facilities for water-borne commerce that made the greatness of Venice; it was their commerce that built up the cities of Holland and in a more recent era the seaports of Great Britain. In our own country down to the middle of the 19th century there were many cities which grew large and wealthy solely by their commerce. Such New England cities as Portland and Salem and New Bedford and New London owed their early prosperity solely to the shipping which sought their harbors. But the revolutionary changes which have taken place in transportation have absolutely altered the influence of commerce upon city growth.

A remarkable illustration of this economic fact is furnished by the city of Galveston. As most of our readers will recall, the United States government some twenty years or more ago ordered a commission of engineers to report as to what port on the Gulf of Mexico could best be improved to serve as a shipping point for the products of the Southwest, so that they could reach deep-water transportation there at less cost than that involved in carrying them a long distance to ports on the Atlantic coast. This commission reported in favor of Galveston as the port to be improved; and the government has since expended large amounts to give Galveston a safe and commodious harbor suitable for deep-draft vessels.

As a result of this improvement, in connection with the development of the Southwest and the increased production of goods seeking a market from that section, the commerce of Galveston has grown by leaps and bounds and its foreign trade is now larger than that of any seaport of the United States, excepting only the port of New York. In the fiscal year of 1913 the total trade of Galveston amounted to $240,000,000, whereas previous to the improvement of the harbor its commerce was comparatively trifling.

If the commonly held ideas as to the effect of commerce on city growth and development were correct, then manifestly Galveston ought to have doubled, or trebled or quadrupled in population in the third of a century which has elapsed since the census of 1880, at which date trade through the port of Galveston was comparatively trifling. Instead of this being the case, however, the growth of Galveston has been extremely small. It had in round numbers 22,000 population in 1880, and in 1910, although the second city in the country in its volume of foreign trade, its total population was only 37,000. Better proof that a great volume of commerce may have little or no effect upon a city's growth in population could hardly be asked for.

When one contrasts the difference between old-time methods of transportation and those in force at the present day, it is not difficult to see why commerce has so little effect upon a city's growth. In the days when wooden sailing ships came up to the wharves of Salem, bringing their cargo of tea and silks from China, there were great profits in the shipping business. These old sailing vessels remained a long time in port and required extensive refitting in sails and rigging and food supplies after every voyage. A whole list of industries prospered at each port upon the ships that brought and took cargo from there. The buying and selling in connection with the goods brought and taken by the ships, moreover, were generally carried on at the port itself, and the opportunities for profit brought a large influx of people to push their fortunes.

All these things have been revolutionized by modern machinery and modern commercial methods. Nowadays, a million dollars' worth of goods may pass through a sea-

port with very trifling toll paid to residents of the port, even in the employment of labor. A thousand bales of cotton, for example, may be bought by a firm in Houston or Fort Worth or New Orleans, or New York City. The cotton is shipped from some interior point to Galveston. The cars containing it run alongside a steamer which may be owned in Holland or Liverpool or Stockholm, a gang of colored stevedores transfers the cotton from the cars to the hold of the vessel and she steams away to her destination. The only toll which any resident of Galveston has obtained from this commerce was the wages paid to the stevedores.

In the handling of grain, the case is even more striking, for the carloads of grain discharge directly into the boot of an elevator and without the intervention of human muscle the grain is stowed in the ship's hold.

Another apt illustration may be found in the transfer between railway cars and lake steamers at the principal lake ports. Buffalo owed its early importance to its position as the western terminal of the Erie Canal and the eastern terminal of the Lake transportation lines. As recently as 20 years ago, the transfer from the vessel to the railway car gave employment to an army of shovelers in handling grain and ore and coal. But modern machinery has now dispensed with the shovelers. Today on some of the great ore docks on Lake Erie an operating force of only three men can move the entire cargo from a big lake ore steamer and place it in railway cars ready for shipment within half a dozen hours.

The same thing is illustrated at the head of Lake Superior where the ports of Duluth and Superior handle a traffic whose tonnage exceeds that of any other port in the world. This vast traffic is handled and transferred with only very trifling tribute to the two cities.

The city of New York 15 or 20 years ago was greatly exercised because its export traffic in grain was slipping away from it. The cost of handling grain through its crowded harbor, with the necessary expenses of lighterage, etc., was such that grain dealers began to send their shipments by preference through such ports as Baltimore, New Orleans, Galveston and Montreal, where the cars could be discharged directly into the ship alongside. It was agitation over this situation that led the State of New York to undertake the $100,000,000 barge canal from Albany to Buffalo so that New York's commercial supremacy should be maintained.

The theory of those whose influence brought about the undertaking of the New York Barge Canal enterprise was that New York City owed its growth and prosperity chiefly to its location at the terminus of the water route from Buffalo to tidewater by way of the Erie Canal. They held that unless the importance of this water route could be maintained by rebuilding the Erie Canal to make the new Barge Canal, New York would decline in population, prosperity and wealth compared with rival Atlantic seaports.

It is interesting now to recall some of the lugubrious prophecies concerning the decay of New York's commerce that were current fifteen years or more ago. The prophecies have indeed proved true in this respect, that the export grain traffic which formerly flowed through New York has been almost wholly diverted to other ports; but the prophesied effect upon the city's growth and prosperity is nowhere to be seen. Grass does not grow in New York's streets; and the chief problem of the city is not how to secure additional population, but how to provide transportation facilities for the vast numbers which every decade adds to its population. Traffic by Erie Canal boats has ceased to have any commercial significance whatever; the new Barge Canal is not completed, and no one in commercial circles betrays any particular interest as to when it will be completed.

In business circles it has now come to be recognized that with railway rates under public control, it is to the advantage of shippers and the public to have as much freight as possible handled by the railways, so that they can afford to handle it at the lowest rate, instead of trying to hamstring them by taking away a part of the traffic and carrying it at public expense on the water route. Enormous as is the volume of New York's commerce, it is after all only a trifling proportion of its enormous population that depends upon that commerce for a living. It is manufacturing industries, and not transportation, that engages the great bulk of its people.

Two other Atlantic Coast cities which have been recently greatly concerned over their commercial facilities are Philadelphia and Boston. Apparently, some of the Philadelphia commercial organizations believe that the future prosperity of the city depends upon the increase of its foreign trade. The absurdity of this is manifest enough when one compares Philadelphia, with its million and a half of population, and Galveston with its 30,000. Were Philadelphia to succeed in increasing its volume of foreign traffic so as to displace Galveston as the second city in the country in volume of foreign trade, it is probable that the resulting increase in its population would be too small for anyone to discern. Here again it is Philadelphia's great manufacturing establishments and not the vessels which enter and leave its harbor, that determine its prosperity.

We are, of course, by no means unmindful in this discussion, of the importance of proper transportation facilities to a city, and especially to a manufacturing city; but good railway facilities, enabling a manufacturer to place his product directly upon a car at the gate of his works, are many times as important to a city's welfare as are its facilities for water transportation, even though the city be located on the seacoast.

Further than this, it is important to bear in mind that improved transportation or transfer facilities at a seaport, are chiefly of benefit, not to the seaport itself, but to all the country which sends and receives products through that port. The cheap route from the Southwest to Europe through the port of Galveston, made possible by the millions expended by the Government in the improvement of Galveston Harbor, has benefited the producers of half a dozen Southwestern States vastly more than it has the City of Galveston itself. Improved facilities for ocean shipment at Boston benefit the State of Massachussetts, and all of New England and other sections which send commerce to that port, far more than they benefit Boston itself.

That the statements made above are well grounded, there is plenty of evidence, in addition to what we have cited above, to prove. These statements have a direct bearing upon the present tendency in numerous cities toward municipal extravagance in connection with transportation facilities. Suppose the City of Galveston 20 years ago had decided that it would itself undertake, at its own

expense, to carry out the work of harbor improvement, and the building of wharves, piers, etc. It can easily be imagined that in the days when the Southern real-estate boom was at its height twenty years or more ago, enthusiasts might have declared that by such a municipal expenditure that city might at no distant day become the second in the country in volume of its foreign trade. It would have been assumed as a matter of course that on reaching that proud position it would have experienced an enormous increase in population and in wealth. It is quite within the possibilities that had not a great calamity overwhelmed Galveston it might have embarked on some such financial venture, just as much larger cities on the Pacific and Atlantic and Gulf coasts are today embarking on large enterprises for the development of terminals for water-borne traffic.

We would not be understood by any means as wholly condemning such enterprises. We have indeed recognized the importance to a city and to its tributary territory of proper facilities for the conduct of land and water transportation. The point we would emphasize is that when a city undertakes such an enterprise it should do it on the same basis as a private investor; that is to say, it should plan to receive a liberal income on its investment from the rental of the privileges which it provides. It should not be deceived by the specious claim that the city can afford to provide such privileges at the expense of the taxpayers because of the indirect benefit that will accrue.

How widespread is the belief in these indirect benefits may be seen in New York City, where there is constant pressure upon the city authorities to reduce the rentals of docks owned by the city, below what will return to the city a fair income on their cost, on the plea that the city must do it because of the indirect benefit it receives on account of the commerce so provided. As we have remarked above, fallacies of this sort are widely held by prominent men engaged in mercantile and manufacturing pursuits and by those who direct influential commercial organizations. It is the business of engineers, however, who carefully study questions of this sort, to hold correct views upon them, and be able to advise the public against unwise and unsafe expenditures.

Letters to the Editor

Longitudinal Expansion Joints in Brick Pavements

Sir—O. M. Severson, in a letter printed in ENGINEERING NEWS, of June 4, raises the question of the necessity for longitudinal expansion joints alongside the curb of brick pavements. He rightly dismisses transverse joints as useless. He might have gone further and said that transverse joints are a positive detriment to a pavement.

I cannot, however, subscribe to Mr. Severson's contention that the only use of a longitudinal expansion joint "of any value is to protect a flimsy curb." "A light curb," says Mr. Severson, "set only in a sandbed, may need the joint, but if the curb is properly built so as to be permanent, it will withstand the pushing due to the expansion of the pavement."

If the steadiness of the curb were the only question involved, no issue would be raised. But, while I do not write in a controversial spirit and have no intention of entering into a controversy, I desire to point to a few facts which Mr. Severson seems to have overlooked, and which, if duly considered, might modify his conclusions.

A curb that could be depended upon to withstand the extreme push of an expanding grouted-brick pavement could surely be built, but probably such a curb would add materially to the cost of construction. Allowing that an ordinary curb needs protection, a longitudinal expansion joint meets the conditions at a minimum cost without impairing the structural integrity of the pavement itself. Therefore the joint is justified by economical considerations.

Possibly I do not define the term "flimsy curb" exactly as Mr. Severson means it to be understood. It seems hardly probable that he [illegible] the standardized stone curb, and I have seen a curb of that kind, a curb having a 4-in. dressed top, and set in 2 ft. of concrete, sheared off at the top and the concrete base heaved by the thrust of expansion in a pavement having transverse expansion joints but no expansion joints alongside the curbs.

This object lesson teaches the possibility, rather than the probability, of a well built standard curb failing to perform its duty; but the lesson has a value—it proves that in order to be absolutely sure that a curb will not yield to the thrust of expansion under any circumstances, it is necessary either to increase the strength of the curb, or buttress it with a sidewalk, or put in a longitudinal expansion joint. The problem of handling expansion is not merely a question of the stability of the curb.

If expansion cannot find relief at the curb, it must be equalized by compression or the pavement will bulge. If we take up the expansion by means of a longitudinal joint, we keep the brick in contact with the sand cushion beneath, thereby preventing the rumbling noise so often heard and usually caused either by the lifting of the pavement or by the settling of the foundation.

The theoretical adequacy of compression to offset expansion is tenable, if at all, only in the case of a pavement lying perfectly flat and level. This type of pavement is never constructed. A crown is necessary for drainage, although the crown should be no higher than is absolutely necessary for drainage. We have in the crown a very different problem from that presented by a flat pavement.

Highway engineers know that a grout bond which fills only the upper interstitial space between bricks, leaving the lower space vacant, acts as a wedge against the bottom or haunch of the joint. This wedge intensifies the upward trend of the applied force, causing the crown of the pavement to strain.

If the thrust of expansion exceeds the ultimate strength of the curb to resist tearing, something must yield—

if not the curb, the pavement. If the thrust of expansion is greater than the resistance, plus the compressibility of the crowned pavement, the pavement will buckle. With only a curved pavement to relieve expansion, compensatory compression is practically a negligible quantity. Thus we have the basic theory of the necessity for an expansion joint along the curb, and generally speaking, engineers are agreed that the theory is sound.

I beg leave also to except to Mr. Severson's statement in substance, that concrete pavements and brick pavements are on a parity in respect of expansion and contraction, although I surmise he did not mean exactly that.

Both materials expand and contract, but not equally, and some authorities claim that both do not expand from the same cause. After expansion or contraction, brick resumes a normal state. Concrete acts differently. Brick is a finished product. After it is laid it undergoes no seasoning process that might cause changes in its density, molecular structure, chemical elements or proportions.

Concrete, being spread while very wet, is expanded by its excess of moisture content. A large percentage of the original moisture content is lost by evaporation during the process of hardening. What concrete gains in density through hardening, it loses in volume, and this shrinkage involves a pulling away of the mass from some original point of contact, or a fracture at some place in the mass. The point of cleavage may be at the curb, but usually longitudinal cracks appear either along the median line of the crown of the pavement or on either side of it, or both, and often it happens that radial cracks appear.

It is well to bear in mind that whether concrete be expanded by heat or by moisture, it never expands after hardening to the extent that wet concrete contracts in hardening. We have, therefore, in a concrete pavement, an initial contraction which never is completely overcome by subsequent expansion; for the reason that the moisture content of the concrete, when it is mixed, is never as great afterward.

The necessity for spreading concrete while it is wet and plastic explains the fact that a concrete pavement cannot be patched satisfactorily. A defective brick can be replaced by a good one; but a wet patch placed in hardened concrete shrinks in drying and pulls away from the adjacent pavement, leaving an interspace between patch and pavement which entirely surrounds the patch.

The crack may not define itself at once, but the line of cleavage is established at the outset of the hardening process, so that the appearance of the fracture is only a question of a short time. Even in the matter of cracks, a wide difference between brick and concrete exists.

A crack in a brick pavement is unsightly and undesirable, but it is not necessarily immediately harmful. Brick pavements often give excellent service for many years after cracks have appeared. Brick does not disintegrate, it wears away by abrasion. But when concrete cracks or pits, it begins immediately to ravel and the progress of disintegration goes on so rapidly that the pavement usually goes to the bad within a comparatively short time.

F. A. Churchill,
Dunn Wire-Cut-Lug Brick Co.

Conneaut, Ohio, June 23, 1914.

A Warning to Railway Construction Engineers Working for English Companies

Sir—Recently a limited liability company organized under the laws of England to engage in railway construction in South America went into voluntary liquidation in England. About 30 engineers, who were employed in South America, were sent home and discharged. All of them were under three-year contracts and had completed about half of their time. A clause in their contracts stated that in case they were discharged the company would pay them six months salary. After reaching England, these men went to the Receivers of the company to get their pay and were informed that the company would only pay £50 to each man.

I am informed that according to English law when a company goes into voluntary liquidation, the salaries have preference up to £50 provided the arrears do not date more than four months back; but any salary accruing after date of the company going into liquidation and all expenses due to the employee and any balance of arrears over the £50 becomes an ordinary debt and is second to the bondholders' claims. The average engineer seems to be under the impression that salaries and wages are preferred claims, but it seems they are not in this case, according to English law.

The Chairman of the Board of Directors of the construction company is also the Chairman of the Board of Directors of the bank which owns all of the bonds.

All of the engineers have claims running from £150 to £1000 each and apparently they will only receive £50 apiece. These men are all capable and honest and the officials who were in charge of the work are also good men; but the bankers and lawyers of the company will find all of their doings looked upon with suspicion in the future.

It would be wise for men who have employment contracts under English law to insist on having their salaries paid at the end of every month.

M. E. B.

Rio Janeiro, Brazil,
June 4, 1914.

NOTES AND QUERIES

A correspondent asks if there is any record of cooling ponds built of reinforced concrete. We have no knowledge of such construction and would be glad to hear from any one who has. Useful information would be in regard to any concrete tank containing water of a temperature of say 200° F., with an outside temperature of 0° F.

※

The Liberalizing Tendencies of Good Roads Enthusiasm is illustrated by two news items of June 19; one is from Cañon City, Colo., stating that the bankers and business men of that municipality "realizing that brawn and muscle are essential to the construction of public highways, have not only subscribed liberally of money, but have gone out with pick and shovel and worked 10 hours a day to improve the roads"; the other item is from Jefferson City, Mo., and states that 40 convicts have been selected for experimental work on the public roads of Missouri. Convict labor is now authorized in practically all the states except Connecticut, Massachusetts, Rhode Island and Minnesota; yet in spite of this road work appears to be looked upon as a fashionable recreation by eminent citizens in many parts of the country.

The Recent Street Subsidences in Paris, France

Following a very severe rainstorm on June 15 the sewers and streets in the city of Paris, France, were flooded to such an extent that severe subsidences took place in three different locations near the center of the city and a number of minor depressions occurred all over the city area. At last accounts about 14 deaths were caused by the accident and it is thought that a number of others may have occurred, the bodies having been washed through the sewers to the Seine and not yet discovered. The cable reports which came first from Paris did not particularize the cause of the trouble, but recent advices seem to show that the subsidences were due primarily to the overflow of flooded sewers into subway excavation.

The city of Paris is now constructing by contract under municipal engineering direction a number of new rapid-transit subways. Owing to the very great complication of underground structures, both of a public-service nature and old building foundations, it has been considered impossible to drive these tunnels by the shield method. At the same time it appears that the Paris engineers are not acquainted with the cut-and-cover method now being so successfully employed in the construction of the New York subways, because it is stated that they cannot allow the stoppage to traffic incident to the open-cut subway construction method. There remains, therefore, only the timbering tunneling method.

The subways now under construction in and around the Place de L'Opera are being driven by the ordinary timbering method; that is, a center heading is first driven and arched up, side excavation being carried out by fan-shaped timbering on either side. Just at present a large part of the subway has the center arch in place, the masonry being supported at its haunches on the as yet unexcavated earth. Above the tunnel arches the sewers and water mains of the city are allowed to remain in their normal position not many feet away from the crown of the subway arch.

Fig. 1. Cave-In in the Rue de la Boetie, Paris, Caused by Sewer Overflow into Subway Workings

(Copyright by International News Co.)

Fig. 2. Cave-In adjacent Place St. Augustin

The rain of June 15 was very sudden, so sudden that it was not possible for the city authorities to control the internal valves by which the excess rainfall flow is diverted from the sewers to the river. Consequently, the sewers soon became full and in places under pressure. It seems that they either began to leak or in places actually broke, allowing the full flood of the excess flow to be diverted onto the subway top where in three places, as noted above, the sides of the arch were undermined and the arch dropped, carrying with it the superposed earth, wire conduits, water and sewer pipes and street paving.

The accompanying views show two of the three large subsidences. Fig. 1 is on the Rue de la Boetie. At this

point it will be seen that the subsidence approached dangerously near the foundation of the adjoining building. Fig. 2 is in the Place St. Augustin. Here in the foreground is a large opening about 50 ft. long, 40 ft. wide and 33 ft. deep, roofed over by the wood-block paving shown. It was in this hole that a taxicab with a driver and woman passenger disappeared, and the man and woman were both drowned.

Report of the Board of Engineers on Flood Control in Los Angeles County, Calif.

In February of the present year the city and county of Los Angeles were visited by an exceedingly heavy rainfall which resulted in a record-breaking flood throughout the entire district. Engineering News in many numbers throughout the first half of this year reported various details of the damage done by the flood water. On Apr. 3, 1914, a committee was appointed to investigate the causes of the flood and to report upon a system of flood control which might be adopted. This committee consisted of H. Hawgood, Chairman, Chas. T. Leeds, J. B. Lippincott, Frank H. Olmstead and James W. Reagan. The provisional report of the Board of Engineers who constitute this committee was made on June 3, 1914. Below is given a brief abstract of the recommendations.

Flood Damage

The committee first sought to compile a record of the flood damage and sent out a number of blanks from which estimates of damages have been made. The data returned to the Board up to June were as follows: Land overflowed, 11,763 acres land totally ruined, 1904 acres land partially ruined, 1081 acres. The estimated amount of losses in ranch and horticulture property is $2,626,845, which includes only about 60% of the loss of the county outside the city of Los Angeles, so that a total ranch or farm loss in the county would be about $4,476,000, to which should be added the losses of the private corporations operating in the county and county highway losses of $2,725,000. Besides this a loss of say $500,000 occurring in the city of Los Angeles may be added, making a total physical loss in the county of $7,601,000.

This amount is only for property or physical loss. In only a few instances were the losses incurred by way of depreciation in value of property included in the estimate. The committee finds that the sum of the depreciated losses and loss due to suspension of business fight total about $2,500,000, making the approximate cost of the floods of February about $10,000,000.

Past Floods

It appears that there had been some heavy floods in the district in 1825, 1833, 1862, 1867, 1884, 1886 and 1889, the flood of 1889 being the heaviest, with perhaps the exception of that of 1862. Since 1889 there have been serious floods in 1891, 1906, 1911 and 1914. This covers a period of 90 years. The mean interval between destructive floods has been about eight years, the maximum interval twenty-nine years, and the minimum three years. Considering the expectancy of floods, it is to be noted that in five years, 1884 to 1889, there were three destructive floods, two of which, notably 1884 and 1889, being among the highest on record.

Recommendations

The Board's recommendations are as follows:

The methods available for flood control are broadly separable into two general classes, opposite in their action: first, those which accelerate the discharge of the main streams, such as the improvement and straightening of channels; second, those which retard and regulate the flow of the feeders into the main stream, such as dams, the spreading of water, the planting and preservation of trees, and especially of low growing brush and willows.

The methods that the Board is able at this time from the data before it to recommend are as follows:

The waterways should be of a type having a channel of moderate width and depth for low-water flow, with levees of such height and set out at such distances apart as would provide an adequate flood channel. The dimensions of the channel should be varied from place to place according to the hydraulic requirements. Protection can be effectually given the levees by revetments and by spur dikes of piles and wire netting. The well-known protection of fascines and mattresses of willow cannot be adopted except in a few places for the compelling reason that the country does not as yet afford a sufficient wealth of willows to supply the necessary material.

The top of the levees throughout their length should be prepared with particular regard to their use by heavy motor trucks. These roadways would be of great value for maintenance service and are in fact a necessity. In making the roadway, oil would be used. The Board is investigating the value of extending the oil into the water face of the levee to furnish resistance to erosion of the light soil, of which many of the levees must necessarily be built.

While flood control by levees in this and foreign countries has been marked by numerous failures and it is impossible to forsee conditions and meet every future contingency, it is a noticeable fact that these failures have been almost universally due either to undue encroachments on the river channel or to insufficient design, inspection and maintenance.

The spreading of flood waters over the gravel deposits and miles of cañons is in general advocated by this Board, it is believed it will indirectly repay in most cases the cost of work from increased irrigation and water-supply alone.

The Board is of the opinion that it may prove a very important factor in avoiding flood damage to construct, according to the Swiss practice, a series of low and inexpensive dams in the upper tributaries of the various watersheds. The effect of this is to change the naturally continuous slope of the stream bed to a succession of steps similar to the drops inserted in irrigation channels to reduce velocity. This method opens the way to vary the time and rate of the maximum flood discharge of the numerous feeders so that the waters from the upper watersheds shall not arrive at the cañon narrows at the same time as the water from the lower side cañon.

There then follows in the report detailed recommendations as to the treatment of the particular rivers which were flooded in the recent floods. The report concludes with the following general recommendation:

The Board recommends that only substantial construction be employed and whatever can be done to commence the work of flood control, even if it be at first only work on the smaller streams and the cleaning of obstructions to the larger, be put in hand with all possible speed. Surveys should be made to define the rights of way for the official channels and to base detail estimates of construction costs upon. All work, irrespective of size, should be approved and supervised by a control board or authority appointed by the county in order that they may be harmonized into one general plan by which means alone can success be achieved. No flood or storm water control, construction, or structure over official waterways should be permitted that is not in accordance with the adopted general plan and approved by this adequate authority.

The Board considers that the construction of the works noted in its report, together with a 25% overhead allowance and including $1,400,000 item for harbor work on six miles of Los Angeles River (which may be considered particularly a federal and state concern and which possibly would be undertaken by the state or the Federal government) would cost about $9,400,000.

A Pittsburgh Railway Station

By G. P. Forsberg*

SYNOPSIS—The most striking feature of the station entrance is the exceptional protection from the weather for those passing to and from the street cars at the station. There is the very unusual arrangement of a shelter roof over the street and sidewalks, with stairways and a subway under the street. The station has forced-draft ventilation, with the air washed and heated, or cooled to suit temperature conditions.

The Pittsburgh & Lake Erie R.R. terminal station and general office building at Pittsburgh, erected in 1900, is located on Smithfield St. at the south end of the bridge over the Monongahela River.

The facilities for caring for passengers arriving at and departing from the station have been enlarged at an expenditure of approximately $12,000, adding the feature of making it possible to pass under cover from train to street car or other conveyance. The general arrangement is shown in Fig. 1, and also by the plan, Fig. 2. The station has both stub and through tracks, and the level of the general waiting room and the concourse and platforms is 12 ft. below the street level. The plan, Fig. 2, represents two levels, but the notes and description will make its meaning clear.

Passengers arriving by train pass from the train shed into the concourse. From this they may pass through the waiting room to reach automobile, cab, street car or sidewalk, or they may go by a more direct route to these same points, under the protection of a covered way outside of the station building but at the platform level, as shown.

The large majority of passengers do not pass through the waiting room, but use the covered way. From the end of this, the passengers may use the stairway to the street or pass through the subway to the east side of the street. The latter is the proper route for passengers taking northbound cars, as its use protects them from crossing at grade a street thickly congested by street-car and vehicle traffic. A "cornerman" is on duty at this crossing for the protection of pedestrians who fail (through chance or otherwise) to use the subway and cross the street and tracks at grade. A suitable booth with glass sides is provided for the "cornerman's" protection in severe weather.

FIG. 1. STREET SHELTER AND COVERED WAY AT THE ENTRANCE OF THE PITTSBURGH & LAKE ERIE R.R. TERMINAL STATION, PITTSBURGH, PA.

The stand for taxicabs, automobiles and cabs, is directly under the Smithfield St. approach to the station, and passengers may reach this stand under cover. Signs are clearly displayed directing the route to be traveled at all points where there is a divergence of routes, so there need be no doubt or misunderstanding in the minds of strangers as to which route they should take.

Passengers arriving at the station to leave by train are afforded similar protection. If they arrive by street car, they alight under the protection of a roof 45 ft.

*Assistant Engineer, Pittsburgh & Lake Erie R.R., Pittsburgh, Penn.

wide, spanning the entire width of Smithfield St. (Figs. 1 and 3). These passengers should use the stairway on the east side of the street, leading down to the subway. From the west end of the subway they may go through the station, if they desire to purchase tickets, check baggage, etc., or, if all this has been arranged, they may go by the more direct covered way to the concourse.

Pedestrians from the north and parties alighting from the street cars who desire to reach the station by crossing Smithfield St. at grade (a bad practice) may either use the covered stairway that leads to the covered way to

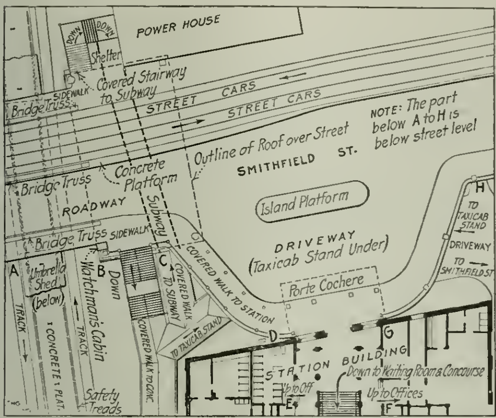

Fig. 2. Plan of Street Shelter, Covered Way and Subway for Passengers; Pittsburgh & Lake Erie R.R. Terminal Station, Pittsburgh, Pa.

the concourse or if they desire to pass through the station they have a covered walk, at the street level, that leads to the main entrance. They may then go down the stairway to the general waiting room, or take elevators to the offices above. Passengers arriving by public or private conveyance alight in the cab stand and reach the concourse by either of the two routes previously described for travel between the trainshed and cab stand, or alight under the protection of a porte-cochere at the Smithfield St. entrance to the station.

Fig. 3 shows an elevation and sections of the shelter spanning Smithfield St., the covered way leading to the station entrance, and the stairway to the platform and subways. Fig. 4 is a cross-section of the subway under Smithfield St., and Fig. 5 is a view of the station end of the subway. This subway is constructed of reinforced concrete, lined inside with white ceramic tile, with a dark

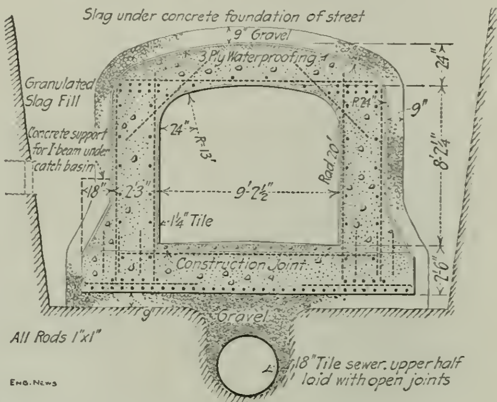

Fig. 4. Cross-Section of Passenger Subway

ceramic-tile base, and granolithic-concrete floor. It is well lighted by electric lights. The heavy reinforcing and the spread of the footings was made necessary on account of the unstable foundation upon which the subway is constructed. Up to the present time, a little more than two years since the construction of the subway, no perceptible settlement has taken place nor have any cracks developed.

Other Facilities

Drinking Water—The sanitary drinking fountains, and the old-type drinking fountains from which water may be drawn for filling individual cups, are supplied with distilled drinking water, cooled by ammonia coils to 45° F. The water is kept in constant circulation by a small pump and returns through a pressure valve to a cedar storage tank so that a person does not have to allow the water to run, but may drink at once. The passenger coaches of all trains leaving Pittsburgh are stocked with distilled drinking water.

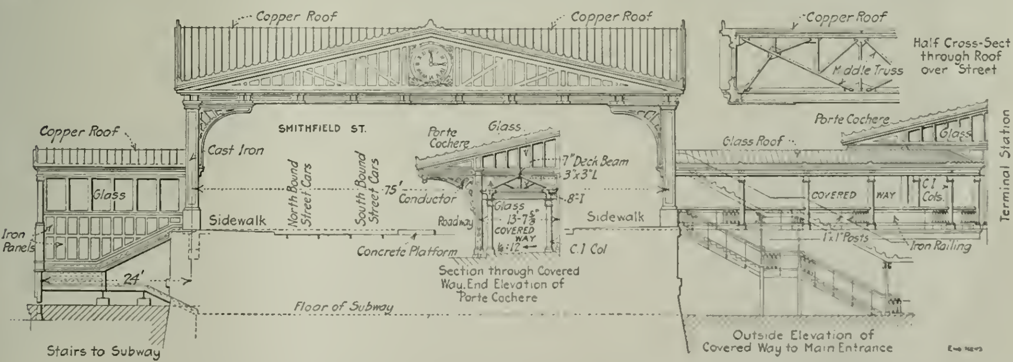

Fig. 3. Sectional Elevation of Facilities at Entrance to Passenger Station

VENTILATION—The ventilating system of the entire building, from which the passengers receive especial benefit in the waiting rooms, is by means of a forced system of circulation. The air is freed from practically all extraneous matter by a washing process and is heated to the desired temperature in winter and cooled in summer. It is then discharged into the rooms approximately at the floor level. At the ceiling are outlets of the same area, which (also by means of forced circulation) draw the air from the rooms at a slightly less rate than it is being delivered. This keeps a slight excess pressure in the rooms, which tends to prevent dust or dirt from the outside getting through any cracks or openings that might exist around the window frames or through exterior doors when open.

This fresh air is delivered and exhausted in such quantities as to change the air in the rooms every 15 min. The window sashes are built in, one sash in each opening being hung on hinges in order that the janitors may get outside to wash them. These windows are kept locked, the janitors having the keys.

GATEWAY RAILING—Fig. 6 shows a detail of the railings at the approach to the ticket gates between the concourse and train shed. This design differs from the ordinary practice in that the top or guard rail is not supported directly on the uprights. The arrangement permits a passenger to walk through the gate rails with a suitcase or valise, without the customary annoyance of striking his burden against the upright supports. At the same time it preserves a distance between the guard rails which insures only one person, at a time, passing through the gate.

FIG. 5. COVERED WAY AND STREET SUBWAY; PITTSBURGH & LAKE ERIE R.R. TERMINAL, PITTSBURGH, PA.

FIG. 6. ARRANGEMENT OF RAILINGS AT ENTRANCE TO TRAIN PLATFORMS, ALLOWING SPACE TO CARRY HAND BAGGAGE

PLATFORMS—The concrete platforms in the trainshed are $12\frac{1}{4}$ in. above the top of the rail, which makes the distance from the platform to the first step of the coach vary (for different classes of equipment) between nothing and $8\frac{1}{2}$ in. This easy rise avoids the necessity of stools being used to assist passengers in boarding or alighting from a train. In the platforms protected by the umbrella shed, safety treads are built in the concrete at the edge of the platform (Fig. 2) in the location that a person would step in alighting from a train.

The terminal station building and facilities were designed in the office of the Chief Engineer, Pittsburgh, Penn.; J. A. Atwood, Chief Engineer, and A. B. Rayner, Assistant Chief Engineer.

Petroleum Production in the United States in 1912 and 1913 was 222,935,044 bbl. and 248,446,230 bbl., respectively. The average value per barrel in each year was [illegible] and [illegible], according to the United States Geological Survey. These figures show that while the gain in output was less than [illegible], the gain in value was almost [illegible]. The output in 1913 was greater than in the previous year by more than [illegible]. Every state except Colorado showed an increase in the value of the oil. The greatest producing districts were as follows in the order named: California, Mid-Continent, Illinois, Appalachian, Gulf, Lima and Indiana, Colorado and Wyoming.

Annual Meeting of the American Society for Testing Materials

The 1914 meeting of the American Society for Testing Materials, held last week (June 30 to July 3) at Atlantic City, was fully as active as its predecessors, which means that it was the busiest engineering meeting of the year. It was distinctly marked by a drifting-apart of committee work and independent papers, evidenced by the fact that few of the papers related closely to subjects of specifications or other committee work. Part of this phenomenon is chargeable to the large amount of subcommittee work which the main committees now carry on. Thus the committee on Preservative Coatings for Iron and Steel has half a dozen or more subcommittees studying various phases of oil analysis, etc., and their results are incorporated in the committee report as small-print appendices, whereas formerly such auxiliary work might have furnished material for independent papers.

This, however, is part of a larger change in the society, which represents an important evolutionary stage.

Great Growth of Committees

The committees of the society are becoming so large as to constitute independent societies, so to say. One of them has 108 members, another 67 members, and several others have over 30 members each. They have their own officers, their own meetings, their own income (contributions solicited from manufacturers), and—as an innovation of the past year—their own constitutions or regulations.

But the most prominent mark of the commanding status of the committees is found in the fact that they have become self-perpetuating. So far as the society membership at large is concerned, the committees are virtually immortal. They control their own membership, and they can be discharged only at their own motion or with their consent, except "for cause," in which case the Executive Committee acts as judge and executioner. At least this is what appears from a new set of Regulations Governing Technical Committees, which are now in force, by virtue of having been promulgated by a special committee.

Another change just made is also a reflection of the magnitude and importance of the committee work. The terms of the officers of the committeees are now limited to two years, just as in the case of the society itself. This arrangement by itself suggests the permanent nature of the committees.

Power of the Membership to Be Limited?

Related to the preceding is a suggestion which Prof. Edgar Marburg (Univ. of Pennsylvania) made in a paper entitled "A Critical Review of the Procedure Governing the Adoption of Standards." He suggests that it is meaningless and undesirable to have the whole society vote on the adoption or rejection of specifications, standard methods, and the like. Committees made up of experts draw up such recommended standards, and the general membership of the society is probably incompetent to pass judgment on the specialized matters presented.

Prof. Marburg did not suggest an alternative; or rather he suggested several, in the form of queries—his paper was largely an assemblage of queries. But any alternative to the present method of taking a vote of the whole society, by letter ballot, on the adoption or revision of specifications, must be a move toward limiting the powers of the members.

The discussion which followed the reading of the paper made it clear that some members would object to a course of this kind. Sharply diverging opinions were expressed. Thus, R. W. Hunt (Chicago) called the letter ballot farcical, and claimed that all doubts or objections to a specification should be fought out on the floor of the society's meeting at the time the committee presents its report. On the other hand, Prof. A. N. Talbot (Univ. of Illinois) favored retention of the letter ballot, and boldly asserted that not all knowledge on a given subject is tied up in the committee which deals with that subject.

No action was taken in the matter, as no specific proposal had been advanced by the author.

Specifications for Engineering Methods

A radical innovation in the society's work presented itself during the meeting in the shape of a specification which, instead of defining a material, prescribed certain methods of engineering construction. So unobtrusively did this make its appearance that no word of comment was uttered, and with smooth dispatch the meeting adopted it for submission to letter ballot, which usually is equivalent to final adoption (no letter ballot having resulted in rejection, in the society's history).

The committee on Drain Tile reported (1) a set of methods for strength tests of drain tile; (2) a specification for quality of drain tile (strength only), and (3) a set of rules entitled "Proposed Recommended Practice in *Design and Construction* of Tile Drains." The latter contained very detailed prescriptions for bedding, backfilling and tamping; and, further, *a table of earth pressure on pipes* in trenches of various widths and depths, for sand and clay. Instructions for using the table, and factors of safety to be employed in designing tile drains, were also given.

Overnight consideration of this proposal resulted in a qualified reconsideration of the approval given these specifications the previous day. A resolution was passed which (1) directs the executive committee to consider the departure from prior policy involved in the formulation of rules on engineering design and construction, and (2) directs the executive committee and the drain-tile committee jointly to consider this question in its aplication to the present case. However, as no formal vote was taken to rescind the meeting's approval, the drain-tile specification will presumably go out to letter ballot in the usual way.

The most important or interesting of the committee reports are summarized below. Elsewhere we give some notes on new data or other useful information contained in the papers presented at the meeting.

Steel Committee

The formidable Steel Committee (108 members, 15 subcommittees) reported a large batch of revisions of existing specifications, and some new specifications. Of the 30 standard specifications previously worked out by the committee, only 11 remained unchanged. All the recommended changes and new specifications were accepted by the meeting and passed to letter ballot of the society. The most important changes are as follows:

Steel Rails

In the face of requests made on behalf of the American Railway Engineering Association to take no action on rail specifications now, the committee revamped its rail specifications thoroughly. It substituted a single specification for the two separate ones dealing with open-hearth rails and bessemer rails; increased the carbon (to a maximum of 0.62-0.75%, for openhearth rails over 85 lb. per yd.); extended the range of sizes down to 50 lb. per yd. and up to 120 lb. per yd.; adopted a ductility measurement in the drop test; abandoned a fixed ingot-discard; and fixed the standard rail length at 33 ft.

Bridge and Structural Steel

While still maintaining the distinction between bridge steel and building steel, the committee made some important changes. Among them are the following:

In *bridge steel*. Strength of rivet steel reduced 2000 lb., to 46,000-56,000 lb. per sq.in., and sulphur raised half a point, to 0.045%; a bend test for eye-bars added; tension tests from angles abandoned.

In *Nickel steel*. Sulphur raised one point, to 0.05%; tension tests of angles abandoned.

In *Building Steel*. Strength of rivet steel reduced 2000 lb., to 46,000-56,000 lb. per sq.in.

A new specification for *Structural Steel for Cars* was drawn up. It calls for metal of 50,000 to 65,000 tensile strength, in plates and shapes over ⅛ in. thick. Parallel with it is the revision of the specification for *Structural Steel for Locomotives*.

Reinforcing Steel

In concrete-reinforcing steel rolled from billets, an intermediate grade was added, between the structural and hard grades. This grade is to have 40,000 lb. yield-point and 70,000-85,000 ultimate tensile strength.

Ductility and Ultimate Strength

In all the above, as well as in other specifications under charge of the steel committee, the elongation requirement will hereafter be made inversely proportional to the ultimate strength, i.e., per cent. elongation equals the quotient of a constant divided by ultimate strength. This calculation, evidently, takes account of the fact that, with the same original material, slight variations of physical condition will shift the strength and the ductility in opposite directions.

A particular application of this calculation led to a warm fight. The specification for *tempered axles* was revised in consultation with a committee of the American Electric Railway Engineering Association. That committee demanded, for electric-motor axles, a high ductility of fixed amount for all tensile strengths within the allowed range. The steel committee declined this demand and stuck to the inverse-ultimate rule. The fight was brought into the meeting, W. V. Johnson appearing for the A. E. R. E. A. committee. The society finally supported its steel committee, and passed the specification to letter ballot.

All other specifications for railway forgings were also revised, and the revisions accepted by the meeting. A proposed standard method for chemical analysis of plain carbon steel was also accepted by the meeting.

C. D. Young (Pennsylvania R.R., Altoona, Penn.) is chairman of the committee.

Wrought Iron

Staybolt iron still occupies the wrought-iron committee (chairman, S. V. Hunnings, Schenectady, N. Y.); a minor change in the existing standard specifications was recommended, and was accepted by the meeting. Vibratory tests of staybolt iron cannot be included in the specifications, the committee reports, because the various testing machines do not agree.

Chain iron will be studied during the coming year. The subject of pipe threads will also be considered.

Cement: The Autoclave Test

The savage fight waged over the autoclave test at the 1913 meeting of the society resulted in the cement committee's finally entering upon consideration of this form of test. Preliminary arrangements have been made for a systematic trial of the test, in which 16 laboratories will assist. Of these 16, no less than 11 were already engaged in making such tests when the committee inquired about the matter.

The Force patent of Feb. 3, 1914, covering the autoclave method of testing cement, is a confusing element in the situation.

The International Association for Testing Materials has, during the past year, reorganized its committee on Accelerated Tests of Constancy of Volume of Cements. R. L. Humphrey (Philadelphia) is the new chairman of this committee. The autoclave test may receive consideration also by this committee.

Two other subjects will be dealt with by the American Society's cement committee during the coming year: the Chapman method of determining consistency, and a standard screen scale.

Lime

Two sets of specifications for lime, covering respectively quicklime and hydrated lime, were prepared by the lime committee for submission to the meeting. At the eleventh hour, however, the committee changed its mind, revised the specifications, and presented them only as tentative, not for present adoption.

These specifications give a classification of limes, limit the carbon-dioxide content, limit the coarse material, and, for hydrated lime, specify a soundness test. Strength requirements are not feasible, and other requirements which would define the product precisely are apparently not possible at the present time.

Drain Tile and Sewer Pipe

Two separate committees are handling specifications for drain tile and sewer pipe respectively. The latter has not yet drawn up a specification, but the drain tile committee (chairman, Prof. A. Marston, Iowa) reported a group of three specifications on methods of test, quality of tile, and proper design and construction of tile drains.

Novel features of these specifications are:

Three methods of making a crushing test of drain tile are described and permitted on equal terms; the results are declared to have certain specified ratios. The strength as given by the sand-bedding method is made the standard of reference, but the assumption is made that this method produces the same bending moment in every case.

Three qualities of drain tile are recognized. Of these, the highest grade must be vitrified salt-glazed clay tile or thoroughly seasoned concrete tile, but the other two

grades may be of any material. The grades are distinguished according to crushing strength, tables of strengths for various sizes being given for each grade.

The specification for design and construction of tile drains has already been mentioned. A factor of safety of 1½ is prescribed for ordinary tile-laying. A table of loads on pipe in trenches, as determined by tests, gives loads for depths of trench up to infinity, and widths up to 5 ft.

These specifications received no discussion at the meeting, but were passed to letter-ballot. A special resolution was passed at a later meeting (as previously noted), calling for consideration of the policy of adopting engineering rules.

The work of this committee is remarkable also for having included a very great amount of experimental work. Full reports of the experiments were published as Bulletin 34 of the Iowa State College of Agriculture & Mechanic Arts, quite recently.

The Sewer Pipe Committee (Chairman, R. Hering, New York) also proposes to draw up a specification for laying pipe, as part of its final report. A memorandum on this subject, and a glossary of technical terms, have been prepared, and were presented at the meeting as tentative.

Road Material, Brick, Cement and Waterproofing Committees Conflict

A set of proposed test methods for specific gravity and absorption of rock, and methods of mechanical analysis of broken stone, gravel, and sand were prepared by the Committee on Standard Tests for Road Materials. But the concrete committee protested that it should have a voice in formulating such methods, and the result was that the proposed methods were referred back, for conference of all interested committees. Definitions for certain terms relating to bituminous materials were also proposed, but here the waterproofing committee protested, and similar action was taken as in the other case.

This led to heated discussion when the brick committee presented a report of progress. The committee on road materials, which had just been treated as noted, made the claim that it should have a voice in considering paving brick. But Prof. A. H. Blanchard's vehement argument to this effect was ineffective, as the meeting voted against the claim.

Paint

The report of the paint committee (Preservative Coatings for Structural Materials) took the shape of a 125-page book. The committee has 67 members and 12 subcommitttees, and carries on a number of elaborate investigations. Detailed reports on laboratory studies of paint materials filled most of the book. Their subjects are: Tests of Chinese wood oil, 22 pages; Tests of linseed oil; Methods of analysis of white pigments and red lead, 20 pages; Turpentine, 28 pages; Other Thinners, 4 pages; Shellac, 7 pages.

Tentative specifications for turpentine, covering some of the properties of turpentine, were presented, but not for present adoption. Several other properties cannot be specified until additional test results are obtained.

A series of definitions of technical terms relating to paint was criticized by C. D. Rinald (Philadelphia), and finally was referred back to the committee for reconsideration.

The Havre de Grace Bridge Paint Test

Eight years ago the committee painted the Havre de Grace bridge, Pennsylvania R.R., with 19 paints. Now many parts of the bridge need repainting and the test is declared ended. On a rating of 10 = perfect, the inspection of the bridge May 1, 1914, showed 9 paints to be in condition meriting a rating of 5.0 or over. The two highest ratings are 8.1 and 7.2. The committee resolved not to make public any information as to the origin of the various paints.

Other Exposure Tests of Paints

The steel-plate panel tests with ocean-side exposure, at Atlantic City, started six years ago by the Paint Manufacturers' Association, has also come to a final end. The last inspection was May 2, 1914. The paint committee of the American Society for Testing Materials has coöperated in these tests. It reported the 1914 ratings of the panels that still survived, but for some unaccountable reason it did not offer a word of comment or conclusion.

White paints are being tested on a test fence in Washington, D. C. This test was started in 1912. Results (for 15 mo.) will be reported in our next issue.

New and Revised Specifications

Besides those noted above, three other new specifications were presented and were accepted by the meeting: Cold-drawn bessemer automatic-screw stock, which describes a dead soft steel of 0.08 to 0.16% carbon; recommended practice for the annealing of carbon-steel castings; hardened steel objects.

The following specifications were revised, more or less extensively: Standard magnetic tests of iron and steel; manganese-bronze ingots for sand castings; spelter; locomotive cylinders.

The committee on Methods of Testing reported a large series of recommended revisions in its specifications. Many of them were based on the use of three-point extensometers, which the meeting was not willing to accept as standard. All the recommendations were finally referred back.

Lubricants were also a subject of contention. Provisional tests for lubricants were presented for adoption. The Saybolt viscosimeter was made standard, though a minority of the committee demanded that the Engler viscosimeter be admitted as alternate. The split on this point resulted in the specification being referred back to the committee for reconsideration.

Progress Reports of Committees

Fireproofing materials are being studied, but further progress waits for extended tests which are to be made this year. One line of study will be materials suitable for furnishing short-time protection to columns and girders of buildings, at less cost than complete fireproofing.

The committee on rubber products has ceased work on air-brake hose but continues work on pneumatic-tool hose. Specifications are being drawn for cold-water hose, low-voltage insulated wire, packing, gaskets, pump-valves and steam hose.

Copper trolley-wire specifications form a subject of nonagreement between the society's committee and a committee of the American Electric Railway Engineering Association. It is proposed to collect data on trolley-wire service which may settle the differences.

The next year committee is working on revision of the malleable castings specifications, as the change in the business due to steel castings taking up the field of heavy castings is making better specifications necessary.

Brick is still in a tentative stage. The provisional specifications presented a year ago are not recommended for adoption, but elaborate tests on relation between strength and absorption, etc., will be made; 24 laboratories will coöperate in the work.

An elaborate progress report was presented by the committee on Sampling and Analysis of Coal. This is the result of joint work with the American Chemical Society, and is the second preliminary report on the work.

The Committee on Specifications for Timber proposes to undertake some work during the coming year.

The address of the retiring president, Arthur N. Talbot, was on the subject "The Relation between Research and the Activities of the Society." It was in part an earnest reminder of the fact that to make specifications and to formulate testing standards requires thorough knowledge of materials and their properties, and that to secure such knowledge calls for much and thorough experimental research. Obviously the society should stimulate research.

Possibly some day there may need to be a general research committee of the society to coördinate work and to stimulate opportunities. * * * Research requires patience, diligence and skill as well as knowledge and opportunity, from outlining the problem and separating the essentials from the non-essentials to analyzing the data and drawing conclusions. See that men of ability and training are selected for such work. Express appreciation of the results obtained and encourage extension of the work. For one function of the society is to widen our knowledge of materials.

In reviewing the available agencies of research the speaker attributed special importance to coöperative studies by committees of the society (and other societies) and laboratories of producers, consumers, independent and schools. One of the instances he cited is of particular interest, on the one hand because it involves exceptional difficulties, and on the other hand because the research will be largely Prof. Talbot's own work. This is the study of stresses in railway track, from roadbed up to rail, which has recently been put under way by the American Railway Engineering Association and the American Society of Civil Engineers.

New Officers

The terms of the principal officers expiring this year, A. W. Gibbs (Pennsylvania R.R.) was elected president, A. A. Stevenson, Vice-President, and Edgar Marburg re-elected secretary and treasurer. The new members of the executive committee are, Robert Job, F. W. Kelley, A. Marston, and S. S. Voorhees.

A group of amendments to the constitution, providing for selection of a nominating committee by the membership, was approved by the meeting and passed to letter ballot.

Useful New Facts About Materials

News and Results Abstracted from Papers Read Before the American Society for Testing Materials

How Strong Is Steel under Repeated Stress?

Steel bridges, axles, springs, shafts, and a great variety of other structures and parts are called upon to endure many-times-repeated stresses. Their safety depends on the ability of the metal to endure stress-repetitions or stress-reversals, rather than on strength under static load. Soft and ductile steel is safe in this respect, as past experiments have shown quite conclusively. But metal which has been partly hardened by cold working may be less safe, inasmuch as it is employed under stresses higher than soft metal could carry, although we do not know that it has greater endurance under repeated stress.

This is one and the most important of the queries propounded by Prof. H. M. Howe (Columbia University, New York) in a paper "Are the Effects of Simple Overstrain Monotropic?" The paper considers whether steel is hardened (its yield point raised) in all directions when it is cold worked in only a single direction. Some tests made at Columbia on the broken halves of a tensile test piece showed practically equal [illegible] hardness in all directions. But in connection with this narrower subject the author deals with many related questions, among them the above-noted question as to strength under repeated and reversed stress.

Experimental work on this important detail, however, seems to be little more than begun. A few quotations from the paper are:

There is much evidence to show that reversing overstrain instead of adding to the [illegible] elevation of the elastic limit and tensile strength caused by prior overstrain, as simple overstrain does, for example in wiredrawing and cold-rolling, has the opposite result of effacing the effects of such overstrain. If this is true, then it follows that any rise of the tensile strength and elastic limit caused by prior overstrain is fictitious as regards the endurance of stress reversals, and that the effective fatigue strength is that which existed before such prior overstrain, and hence that to which the metal would return on removing that overstrain by annealing at [illegible].

This hypothesis [illegible] would imply that cold-rolled shafting, cold-drawn wire and like materials have no greater endurance than the same materials when annealed.

If it is true that stress reversals efface the elevation of the elastic limit due to prior overstrain, but elevate that caused by cold-rolling or [illegible], then it seems to follow that [illegible] specifications for objects which in use are subjected to vibratory stress reversals should [illegible] such elevation.

[illegible]

Internal Fissures in Steel Caused by Defective Manufacture

A large locomotive driving axle broke while in the lathe, before it had been in service. Examination by Robert Job (Montreal, Que.) showed a large transverse fissure 8 in. in diameter, at the point of fracture, which left only a narrow ring of solid metal around the periphery. There were also some longitudinal cracks. The

steel contained 0.48% carbon, low phosphorus and sulphur, and was not segregated, nor did it contain excessive slag. Microscopic examination showed evidence of uneven heating, and overheating on one side. The case proves that an internal transverse fissure may be produced in metal at the mill and as a result of severe stresses induced by defective mill practice.

Prof. H. M. Howe suggested that such cracks probably result often from charging a cold ingot into a hot furnace. Snapping sounds are given out by such a piece as it heats up, suggesting that the cold interior is torn apart as the outside heats up.

An Accelerated Endurance Test for Metal Coatings

The protective value of galvanizing and other metal coatings has hitherto been largely subject to guess. Exposure tests are likely to vary in their conditions so greatly as to vitiate comparisons; the fact that they require a very long time before any results whatever are obtainable makes them inapplicable as routine acceptance tests. No accelerated test of general applicability had been devised. Now, however, a very promising test has been developed in the laboratory of the General Electric Co., and the company's testing engineer, J. A. Capp, described it under the title "A Rational Test for Metallic Protective Coatings."

The test consists in exposure of the test articles to a saturated salty atmosphere. An atomized spray of water saturated with common salt is projected into the chamber containing the articles. Rust appears very quickly, in times ranging from an hour or two to several weeks. This length of time is taken as measure of the protection afforded by the coating. The rusting usually is practically uniform over the whole surface of the article; when certain parts of the surface (as the edges of screw-threads on a threaded article) show rust much earlier than other parts, the coating is evidently thin or weak at these points.

The spray test (without salt) was first used as an accelerated test of insulations. In applying it as a rusting test to galvanized or sherardized articles, the simple water spray was too slow; by adding salt, much more rapid action was obtained. In this form it has been in regular use for several years past in the laboratory above mentioned.

When the coating is relatively thin and poor, rust may develop in from 2 or 3 hr. to 24 hr., or longer. A better coat will last two or three days, but a well applied coat of requisite thickness will last at least a week. If no rusting is developed in two weeks' time, it may safely be assumed that the life of the coating will be practically indefinite. These figures are based on experience with both sherardized and galvanized types of coating.

The standardization and adoption of such a test is likely to have a considerable effect in promoting the intelligent selection and use of metallic coatings.

Paint on Cement or Concrete Surfaces

H. A. Gardner (Washington, D. C.) adds materially to the few existing data on painting concrete. A two-year test of 35 different paint mixtures applied (3 coats) to separate panels of a cement-stucco test fence in Washington shows that good oil paints give very satisfactory service on cement surfaces, while water paints and varnish or other resinous paints do not. A priming coat of 25% zinc-sulphate solution was applied to the panels, to neutralize any free lime, but this is held to be unnecessary if the surface is dry when painted and will not be exposed to the weather. The oil paint is not attacked by the dry cement, and holds both texture and color. Boiled linseed oil, mixtures of raw and boiled oil, and mixtures with Chinese wood oil, gave equally satisfactory results. Such simple paint coatings were also found to be excellent for concrete floors, being durable, wear-resisting, and dust-preventive.

The Strength of Slag Concrete

Although much concrete made with blast-furnace slag as aggregate is in service (and has been in service for years), there are still many who doubt the strength and the permanence of such concrete. As to strength, new data have been provided by W. A. Aiken (Philadelphia). He started an extensive series of tests a year ago, making 500 six-in. cubes of 1 : 2 : 4 cement-gravel-slag mixture. The sand "was not what could be considered first-class material." Of the total number, 400 have already been tested; the other 100 are to be tested at future periods. The average crushing strengths obtained were, in pounds per sq. in.:

SLAG CONCRETE. AVERAGE WEIGHT 140.8 LB. PER CU.FT.

Age	28 d.	3 mo.	6 mo.	9 mo.	1 yr.
Crushing strength.....	1561	1952	2589	2841	2797

The author interprets these figures as follows:

The main point is whether the compressive-strength values herein developed are sufficiently great to warrant the employment of slag as aggregate, in competition with broken stone and gravel. We think the findings are in favor of this, since our experience has been that the crushing strength of broken-stone or gravel concrete, made up under ordinary field conditions, will not average over 1500 lb. per sq.in. at the age of 30 days.

Slag varies widely, both physically and chemically. That firm slag will make a strong concrete has never been much in doubt. Naturally, the discussion of the paper dealt with the permanence of slag concrete rather than its strength, although Mr. Aiken gave no data on permanence. Opposing opinions were expressed. R. L. Humphrey (Philadelphia) mentioned having examined many cases of disintegrated concrete made with blast-furnace slag. He claims that slag if suitable is excellent for concrete, while if unsuitable it is the worst material that can be used.

Expansion and Contraction of Concrete with Wetting and Drying

Experiments by Prof. A. H. White (Univ. of Michigan) reported three years ago showed that concrete expands by wetting and contracts by drying, in amount sufficient to affect structures quite seriously. Continuation of these experiments has shown that these volume changes do not decrease or stop with age. Further, bars cut from sidewalks after 20 yr. service also show these phenomena, and retain them even after baking at 600° F.

Progressive expansion or contraction may also occur. A bar of neat cement could by successive bakings be made to contract as much as 1.6%. Bars of 1 : 3 sand mortar could, by successive bakings and boilings, be made to elongate 0.75%. Bars cut from sidewalks taken up after 20 yr. service were made to elongate 0.175% by successive immersions in water at room temperature; it

would take 200° F. temperature rise to produce an equal heat-expansion.

Full data on these tests are given in Prof. White's recent paper "Volume Changes in Portland Cement and Concrete." The author suggests that the observed phenomena represent serious causes of destruction of concrete in service. But on this point the concrete men disagree with him heartily. They have asserted that his test conditions are artificial. The permanence of concrete pavements and sidewalks is claimed to be a sufficient answer to his allegations.

Additional Results Obtained with Autoclave Test for Cement

H. J. Force (D., L. & W. R.R., Scranton, Penn.) reported new figures on the relation of tensile strength, compressive strength, and air and water storage, to aging of cement-mortar testpieces. Tensile tests of 1:3 briquettes, tested up to 1 yr., do not show very marked influence of the ability of the cement to pass the autoclave test. But in the compression tests up to 1 yr., the cements which failed to pass the autoclave test were much lower than those which passed the test.

Briquettes stored in water for varying periods up to 2 mo., then tested by autoclave and broken in tension, showed that "seasoning" was frequently not obtained by the water storage. Many of the 2 mo. briquettes failed in the autoclave test, but cement which passed the test in 24-hr. briquettes did not fail in the test at subsequent periods.

Briquettes stored in air for 18 mo. were in some cases not "seasoned" with respect to the autoclave. But those which passed the autoclave test at 24 hr., and gave high tensile strength, also gave high strength after passing the autoclave at the age of 18 mo.

Test for Concrete Aggregate

C. M. Chapman (Westinghouse, Church, Kerr & Co., New York) has tried the following test of the value of broken stone, etc., for use as aggregate in concrete. A skeleton testpiece of the stone to be tested is formed by filling the stone into a mold and then filling the interstices with a standardized grout; then this skeleton testpiece is crushed at 14 or 28 days. The compressive strength so found is taken as a measure of the value of the stone.

In actual manipulation, the stone after first being soaked in water, is mixed with the 1:1 standard grout, the surplus grout drained off through a $\frac{1}{4}$-in. sieve; the stone so coated with grout is then put in the mold and shaken and rodded down, and the rest of the grout poured in to fill all voids. A 6-in. cylinder 6 in. high is one of the shapes tried.

[Other abstracts will follow in next week's issue.]

Test for Fireproofing—A test structure for conducting tests of fireproofing and fire-resistive coverings for structural members is being erected at the Underwriters' Laboratories, Chicago, the Western [illegible] Fire Insurance Companies cooperating in the enterprise. The test structure, it is claimed, will be the most [illegible] of the kind ever built. Temperatures will be measured with great accuracy. Many kinds of tests can be made. The Bureau of Standards may assist in conducting the tests.

A New City Charter for St. Louis

The city of St. Louis, on June 30, by a vote of 46,839 to 44,158 adopted the new charter prepared by the Board of Freeholders. The Board of Freeholders consisted of six lawyers, six business men and one engineer, Edward Flad, M. Am. Soc. C. E., for several years Water Commissioner of St. Louis.

The new charter provides for a single legislative body, a Board of Aldermen, consisting of 28 members. The Mayor is the chief executive and responsible officer, and appoints the administrative heads of all the departments. His salary is $10,000 per annum. He and all other elective officers are subject to recall. There are also the usual provisions for initiative and referendum. No recall petition can be filed within six months after an election.

Of the most interest to engineers is the Board of Public Service, which is appointed by the Mayor. This board is composed of a President and four Directors: the Director of Public Utilities, the Director of Streets and Sewers, the Director of Public Welfare and the Director of Public Safety, each the head of a Department of the same designation. The salary of each member of the board is $8000 per annum. According to Section 2, Article XIII,

> The President of the Board and the Directors of Public Utilities and of Streets and Sewers shall be engineers of technical training, of at least ten years experience and qualified to design as well as to direct engineering work.

The President of the Board has charge of any public works undertaken by the city which are not assigned to special departments. The Department of Public Utilities, which includes water-supply and city lighting, has general supervision over maintenance, equipment, operation and service. Under the new charter the city may buy and operate any kind of a public service. The water-supply is a subdivision under a Water Commissioner. The work of the Department of Streets and Sewers includes garbage and refuse collection and disposal, bridges, wharves and levees. The Department of Public Welfare includes parks, hospitals and penal institutions, including a division under the Health Commissioner. The Department of Public Safety includes police and fire-protection, weights and measures, and building inspection.

All subordinate employees are examined and selected by an Efficiency Board consisting of three members appointed by the Mayor. The Board may call on other persons to frame questions and conduct examinations or tests. Any appointing officer may suspend or discharge or reduce in rank any employee under him. So far it is merely a civil service board, but in addition to these powers it is also to investigate and keep a record of the efficiency of officers and employees in the classified civil service, and requires reports relative to employee's efficiency from appointing officers.

The purchases for all city departments are made through a Supply Division of the Department of Finance, which is distinct from the other city departments and is under the general supervision of a Comptroller elected by popular vote. The subordinate officers of the Department of Finance, the Assessor, Collector, Treasurer, and Supply Commissioner, are appointed by the Mayor. The Supply Division does not have jurisdiction over the purchase of material for public works and improvements.

The Largest Pumping Plant in the World: a Great Humphrey Engine Pumping Plant for Land Drainage in Egypt

The Egyptian government has just awarded to the Humphrey Pump Co., Ltd., of London, a contract for ten Humphrey direct-acting explosion pumps with a combined capacity of a billion Imperial gallons per 24 hours for use in drainage of the Nile Delta at Mex, Egypt. This will be, we believe, in volume of water handled, the largest pumping station in the world, if not at first then certainly when it reaches its ultimate size, as provision is to be made in the construction for the addition of eight more pumping units, giving it a total possible output of 1,800,000,000 gal. per 24 hours. In making comparisons, of course, it must be remembered that these are Imperial and not United States gallons.

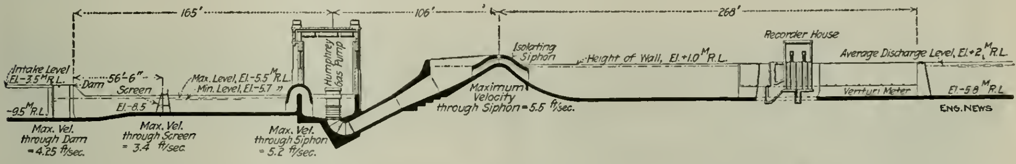
The only pumping installation we can recall which might possibly compare in volume of water handled with this great Egyptian plant is some of the screw propeller pumps, built to force a current of water through a tunnel for flushing out river channels, such as the well known plant at Milwaukee. These screw-propeller pumps operate, however, under a very small head, whereas the Humphrey pumps at the Mex station will lift the water 19 to 20 ft. According to the information furnished to us, the purpose of this great pumping plant is to furnish drainage for a considerable part of the Nile Delta. The drainage from a large area of irrigated land flows into Lake Mareotis, beside which the station is to be built. The pumps will lower the level of this lake 7 ft. and will then maintain it at this lower level. Each pumping unit is to be designed for an output of 68,750 Imp. gal. per minute normal rating (100,000,000 gal. per 24 hr.), with an overload capacity of 75,625 Imp. gal. The pumps will be supplied with producer gas made in Dowson producers from anthracite coal. The contract awarded includes besides the pumps the necessary screens, sluice gates, etc., the gas producer plant, auxiliary gas engines and electric generators for power and lighting, and Venturi meters for recording the flow in the conduits. The accompanying cut gives a profile and cross-section of the new pumping station as now designed.

The great size of the pumps may be judged from the fact that each unit is to be capable of delivering more than double the amount delivered by each large Humphrey pump unit installed at the Metropolitan Water Board's Pumping Station at Chingford, which have an output of 40,000,000 gal. per day each.

The maximum internal diameter of the combustion chamber will be 8 ft. 8 in. and its height about 11 ft. The water valve box will be 8 ft. 8 in. diameter and 7 ft. high, and will be fitted with 100 valves of the hinge type specially designed to enable any valve to close upon an obstruction, such as a piece of wood, without throwing undue strain on the hinges. The design is such that on the next stroke, when the obstruction has been removed by the rush of water, the valve will automatically readjust its position and close fairly upon its seat. This type of valve has proved itself thoroughly satisfactory under test.

All the main castings will be of steel, and will be carried upon a cast-steel bend which connects to the playpipe. This bend will be in two parts, making up the 118.5° required to connect with the inclined playpipe.

At Chingford, the bend has an angle of 90° and connected to a horizontal playpipe, which in turn connected through a second 90° bend to a vertical conical water tower. At Mex, however, there will be only one bend, and the playpipe is sloped upward so as to deliver the water at the required elevation in the discharge basin. In order to reduce the velocity of the water at the exit, the playpipe ends with a long conical portion giving a 12-ft. diameter outlet. Not only does a sloping playpipe eliminate one of the bends and give rise to a simpler construction, but it has the additional advantage that the vertical components of the forces due to momentum of the moving masses of water in the combustion-chamber portion and playpipe portion, respectively, are balanced.



LONGITUDINAL SECTION THROUGH CONDUITS OF HUMPHREY GAS PUMPING STATION TO BE BUILT AT MEX, EGYPT

The pumps will be started by forcing into the combustion chamber a mixture of gas and air which is exploded by means of the usual sparking plug and switch so as to give rise to the first oscillation, after which the working becomes automatic. Compressors capable of rapidly charging the pumps for this purpose and having separate cylinders for air and gas are included in the contract.

Five of the pumps will be made by Wm. Beardmore & Co., Ltd., of Glasgow, and five by the Tecnomasio Italiano Brown Boveri at Milan.

The anthracite gas plant will be capable of gasifying 44 tons per day. There will be nine producers, one of which will be a spare.

There will be two Venturi meters supplied by George Kent, Ltd., each arranged to measure the water delivered from one or more pumps up to a total of five. These meters will be of square section and 12x12 ft. in the throat. The meters are guaranteed to be accurate within $1\frac{1}{4}$%. Except that the throat diameters will be lined with gun-metal to insure smooth and accurate stream lines they will be mostly constructed of $\frac{3}{4}$-in. steel plates bolted to rolled-steel joists and jointed with lead strips. The meters will be partly supported in the natural rock as excavated and partly by concrete walls.

The whole of the work will be carried out under the

supervision of Harper Bros. & Company, Consulting Engineers to the Egyptian Government.

We are indebted for the above information to the owners of the American rights to the Humphrey patents, the Humphrey Gas Pump Co., Syracuse, N. Y.

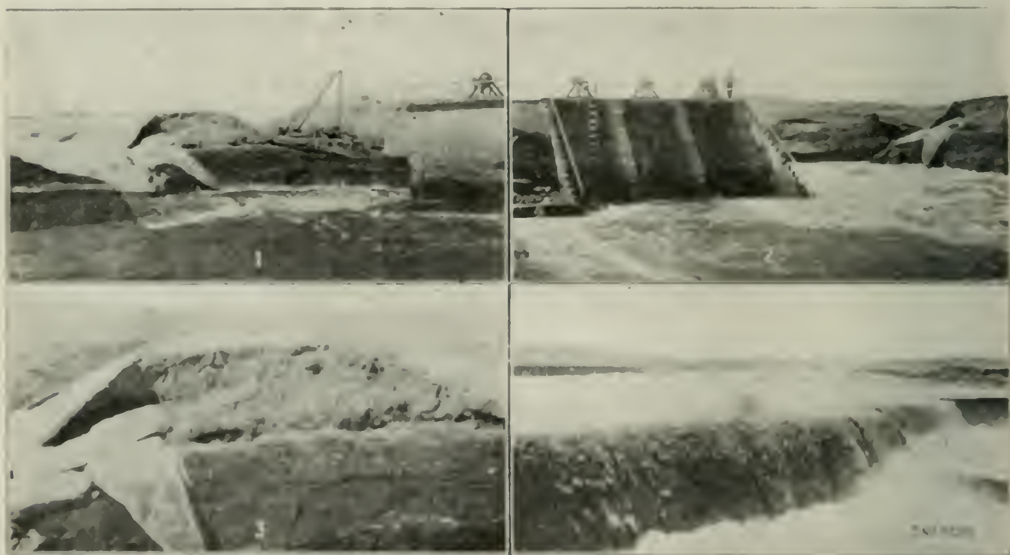
Reservoir Embankment Failure; Turlock Irrigation District, California

(CONTRIBUTED)

The break in the embankment of Davis reservoir, Turlock Irrigation District in Stanislaws County, Calif., was an accident of no little engineering interest so that available details should be put on record. The immediate damage to the irrigation works is comparatively small (possibly $50,000) but the loss to the community from crops ruined by the deprivation of water, may amount to a million dollars or more, if water is not quickly restored. However, a large force of teams was put at work immediately to construct a new canal [illegible] and the District officials hope to resume irrigation service in about 20 days.

CANAL AND RESERVOIR—The main canal of the Turlock Irrigation District heads on the Tuolumne River at the La Grange Dam about [illegible] miles east of Modesto. From the intake the canal runs generally west for 10 miles and empties into Davis reservoir. This latter has what is locally termed a "[illegible]," covering [illegible] acres, and having a maximum depth of 40 ft. and a capacity of [illegible] acre-ft. It is formed of a series of earth dams with concrete facing built last winter. The natural formation at the [illegible] grounds is 30 to 40 ft. of fine sandy soil, and sand of various degrees of fineness which in places is cemented so as to form a hardpan. The outlet structure is located in a deep cut made through this latter material. In placing the outlet, which consists of three radial gates, a cut was made considerably wider than the structure itself and the backfill was dumped in wet and, some claim, not puddled. A 6- to 8-in. concrete face was placed on the face of the fill and extended into the bottom hardpan several feet. This facing connected with the gate structure but the sides of that structure were made smooth without any cutoff walls or wings.

Water was first turned into the reservoir early in April before the reservoir structures were complete, and on June 27, the gage registered 38 ft.—nearly the full capacity. Soon after the reservoir was finished a number of water users protested against the acceptance of the work by the District, claiming that the filling had not been properly puddled and that the packing was cracking. There was reported a small leakage around the outlet structure. Some repairs were made but the leakage continued.



FIGS. 1 TO 4. VIEWS OF DAVIS RESERVOIR EMBANKMENT FAILURE

[illegible]

THE FAILURE—At 2 a.m., June 27, the night watchman at the reservoir discovered that water was pouring through a hole on the right side of the gate structure, was rapidly tearing away the fill on that side and was cutting into the original hardpan sides. At 9 a.m., this gap had widened to 60 or 70 ft., and it is estimated that water was pouring through at the rate of 18,000 cu.ft. per sec. The water was carried by the canal a short distance and then broke its banks and overflowed into the Tuolumne River, finally cutting a deep, wide channel to the river, and washing out, beyond repair, about a mile of the canal. At this time (June 28) water is still flowing out and it will probably take several days to

FIG. 5. MAP OF TURLOCK DISTRICT

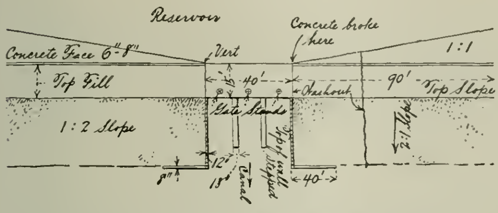


FIG. 6. SKETCH OF GATE STAND AND EMBANKMENTS AT BREAK (DIMENSIONS APPROXIMATE)

empty the reservoir. Figs. 1-4 show photographs taken on the morning of the 28th, when there was some 15,000 acre-ft. in the reservoir and about 10,000 sec.-ft. flowing out the break. Fig. 5 is a map of the district and Fig. 6 is a sketch, hastily drawn, of the gate and embankments.

CAUSE OF THE FAILURE

The cause of the break may be attributed to any one of several conditions which were found to exist.

(1) There was no provision for any cutoff wall on the side of the gate structure except the thin concrete facing. The structure presented a perfectly smooth surface and the new fill and small holes through the facing next to the wall would have led to an easy discharge path along this wall.

(2) The partly washed-out fill on the left side of the structure showed that it was composed of boulders, lumps of rock and hardpan and a fine sandy soil. Although it is claimed that this was puddled in place, some persons who witnessed the construction declare that the material was merely dumped from cars into a pool of water that was maintained in the center of the fill. The present exposed fill shows that the mass was not thoroughly compacted and not of very well selected material.

(3) The concrete facing on the fill is said to have extended 2 to 3 ft. into the hardpan on the bottom. When water was first placed in the reservoir and before it had attained any considerable head against this facing, leakage developed, which was apparently from under the fill. It is the opinion of some who watched the construction of the fill that this leakage was the cause of the failure.

A Proposed Deferrization and Demanganization Plant for the Lowell, Mass., Water-Supply

A novel water-purification plant for the removal of both iron and manganese from well water has been recommended to the city of Lowell, Mass., by F. A. Barbour, Consulting Engineer, Boston, Mass. The plans have been approved by the State Board of Health, and it is expected that bids for construction will soon be invited. The works have been designed for a nominal daily capacity of 10,000,000 gal., or a net average daily capacity of 7,500,000 to 8,500,000 gal. They include six coke prefilters, 10 ft. in depth and with a total area of 0.4 acre, to be operated as contact beds; a 500,000-gal. settling basin, in two units; 6 sand filters with a total area of one acre; and a 1,000,000-gal. filtered-water reservoir.

The nominal daily capacity of 10,000,000 gal. is based on a 75,000,000-gal. rate through the prefilter and a 10,000,000-gal. rate through the sand filter. The net rate mentioned allows for cleaning and for a possible lower rate of prefiltration. The estimated cost of the purification plant, low-lift pump to serve it and pipe connections is $180,000; to which $30,000 should be added for an extension of the well system to insure a supply equal to the capacity of the proposed purification works. The average cost of iron-and-manganese removal under these plans for the next 25 years is $7.65 per 1,000,000 gal., including interest, depreciation and operating charges.

Before deciding on the system of water treatment recommended, a long series of experiments was made on the removal of iron and manganese from the well water, and also another set of experiments on the decarbonation of water from another group of wells, the excessive carbon dioxide in which has given rise to lead poisoning and the consequent use of the wells only in times of high consumption. The design of the deferrization and demanganization plant was based on the experiments just mentioned. The decarbonation tests showed that the carbon dioxide could be removed by fine-spray aëration, in case it becomes desirable to use regularly the water.

In addition to the experiments with the well water, estimates were made of the cost of obtaining supplies from the Merrimac River, filtered, and from the Metropolitan water-works at the Wachusett Dam. The latter was found to be prohibitive in cost. A filtered supply from the Merrimac would cost about $250,000 for construction and $10.27 per 1,000,000 gal., including operating and capital charges. This is $2.62 more than the cost of iron-and-manganese removal, but the cost of maintaining the well system is estimated at $1.40 per 1,000,000 gal., which makes the filtered Merrimac supply less expensive by $1.78. Mr. Barbour considered this possible saving in cost more than offset by "the greater safety of the ground water, the lesser color, the lower temperature in summer, and the popular prejudice against the use of a polluted river water, however well purified."

TABLE SHOWING ANALYSES OF WATER SUPPLY OF LOWELL, MASS., FROM 1896 TO 1913.

Period	Color	Total solids	Ammonia Free	Ammonia Albuminoid	Chlorine	Nitrates	Nitrites	Oxygen consumed	Hardness	Iron
1896-00	15	44.2	0.087	0.032	2.7	0.261	0.001	0.7	17.6	0.322
1901-05	11	44.2	0.040	0.035	2.5	0.157	0.001	0.8	17.0	0.341
1906-10	25	42.7	0.131	0.048	2.8	0.098	0.001	1.1	18.5	0.770
1911-13	36	61.8	0.067	0.067	3.8	0.117	0.001	...	28.0	1.468

Deferrization and Demanganization Experiments

In 1893, Lowell put down a gang of driven wells in the valley of River Meadow Brook, known as the Cook Wells, and in 1894 put down another gang, a mile farther upstream, called the Hydraulic Wells. Together these wells yield about 5,000,000 gal. per day. The State Board of Health having concluded that these wells would not yield more than half the amount of water needed by the city, a contract was let in July, 1895, for driven wells, two miles above the Pawtucket Dam, between the Merrimac River and the Boulevard—hence the name, Boulevard Wells. A total of 160 wells yielded about 4,000,000 gal. a day. In 1899, the Cook supply was condemned because of lead poisoning through the action of carbonic acid on lead pipes. In 1900 and 1901, there were added to the Boulevard system 177 wells, making 341 in all. In 1911, there were added 118 wells, bringing the total up to 459. In 1902 and 1903, the Cook wells were not used, but since then they have been used for short periods each year, to the extent of 3.2% of the total consumption in 1904 and 28% in 1913.

With the increased draft on the Boulevard wells the water has become turbid and colored, due to increasing amounts of iron and manganese—although it does not appear that manganese determinations were made until recently.

The five-year averages of chemical analyses (in table on page 107) of the Boulevard well water, made by the State Board of Health, are of interest as showing (particularly by iron and ammonia) the effect of "overworking the soil" from which the water is drawn (quantities in parts per 1,000,000):

It will be noted that although the last period is for three years, only the iron and other mineral contents showed a greater increase than in the five-year periods. It may be added that analyses made from August, 1913, to April, 1914, showed weekly averages ranging from 1.[illegible] to [illegible] of iron and 1.7 to 3.55 of manganese (p.p.m.). Mr. Barbour states that with 1.6 parts of iron and 3.2[illegible] of manganese, 19[illegible] lb. of these two metals were being pumped into the water mains.

The 118 wells added in 1911 made "a temporary improvement in the quality of the supply, but within a few months, metal contents again increased to a point which rendered the supply disagreeable and altogether unsuitable for domestic service."

Experiments on this water were conducted with as much regularity as pumping conditions warranted from September, 1909, to April, 1914. Water was pumped to an overflow tank, passed through an orifice to a prefilter and then to a sand filter provided with a rate controller. The desired rate of filtration was maintained by meters and daily calibrations.

A series of [illegible] experiments is outlined and summarized in the report. We give here only the summary and conclusions, as follows:

[illegible]

[illegible]

[illegible] quent filtration through sand at a rate of 10,000,000 gal. per acre daily.

On these conclusions, plans of a purification plant have been prepared, based on the use of coke prefilters 10 ft. deep, an intermediate sedimentation basin of 1 hr. capacity, and sand filters 3 ft. deep. The depths of both filters are greater than in the experimental apparatus, and the addition of the intermediate sedimentation basin will serve to reduce the work to be done by the sand filter. It is believed the experiments were sufficiently prolonged, and on such a scale as to permit safe conclusions to be drawn, and that there can be no doubt that the plant designed will successfully remove the iron and manganese and render the Boulevard supply entirely satisfactory.

Estimated Cost of Deferrization and Demanganization

An outline of the proposed plant and costs of construction and operation have already been given. The prefilters would be above ground, and apparently without a roof. The inner walls of the prefilter would be carried up and a roof thrown across to house the operating gallery. In front of this a headhouse and laboratory would be built from which the main operations of the whole plant would be controlled. Still farther to the front, the settling basins would be located, with the sand filters on either hand and the filtered-water reservoir in front. The settling basins, sand filters and filtered-water reservoir would all be underground, built of concrete, with groined arches.

Some of the unit construction costs are as follows: Earth excavation and embankment, 70c. per cu.yd.; concrete masonry, $9.50 per cu.yd.; steel reinforcement, 4c. per lb.; coke, $2.50 and gravel and sand each $2.25 per cu.yd. The recording apparatus complete is estimated to cost $3500.

The cost of treated water per 1,000,000 gal. has already been given as $7.65, as an average for the next 25 years. This is based on the following detailed estimate for a daily rate of 5,800,000 gal. in 1915 and 8,400,000 in 1940.

	1915	1940
Fixed charges at 6%	$1[illegible]	$1[illegible]0
Fuel, low-lift pumping	[illegible]	6,1[illegible]
Oil, waste, etc.	3[illegible]	4[illegible]5
Scraping, washing and replacing sand	2[illegible]	4[illegible]
Three filter attendants	[illegible]	3,0[illegible]
Superintendence, laboratory maintenance	1,5[illegible]	1,[illegible]
Total cost per annum	$1[illegible]3[illegible]5	$2[illegible]71[illegible]
Cost per 1,000,000 gal.	[illegible].60	[illegible]
Cost without fixed charges per 1,000,000 gal.	3.51	3.2[illegible]

The present Holly pumps would lift the well water to the coke prefilters and two new steam-turbine-driven centrifugal pumps, located in a small extension to the present pumping station, would lift water from the filtered-water reservoir into the force main leading to the West St. pumping station.

James H. Carmichael is Commissioner of Water and Fire Protection of the City of Lowell, and Robert H. Thomas is Superintendent of Water Works.

Proposed California Law to Regulate Expert Testimony

Oscar C. Mueller, attorney, of Los Angeles, Calif., in collaboration with others, has drawn a proposed code to regulate the testimony of experts in trial cases, which has been approved by various professional organizations and will be presented to the next legislature by Mr. Mueller,

who is chairman of the committee on amendment of laws of the Los Angeles Bar Association. The following is the text of the proposed law:

Whenever it shall be made to appear to any court or judge thereof, either before or during the trial of any action or proceeding, civil or criminal, pending before such court, that expert evidence is, or will be required by the court or any party to such action or proceeding, such court or judge may, on motion of any party, or on motion of such court or judge, appoint one or more experts to investigate and testify at the trial of such action or proceeding relative to the matter or matters as to which such expert evidence is, or will be, required, and such court or judge may fix the compensation of such expert or experts for such services if any, as such expert or experts may have rendered, in addition to his or their services as a witness or witnesses, at such amount or amounts as to the court or judge may seem reasonable.

In all criminal action and proceedings, such compensation so fixed shall be a charge against the county in which such action or proceeding is pending and shall be paid out of the treasury of such county on order of the court or judge. In all civil actions and proceedings such compensation shall, in the first instance, be apportioned and charged to the several parties in such proportion as the court or judge may determine and may thereafter be taxed and allowed in like manner as other costs.

Nothing contained in this section shall be deemed or constructed so as to prevent any party to any action or proceeding from producing other expert evidence as to such matter or matters; but where other expert witnesses are called by a party to an action or proceeding they shall be entitled to the ordinary witness fees only and such witness fees shall be taxed and allowed in like manner as other witness fees.

Any expert so appointed by the court may be called and examined as a witness by any party to such an action or proceeding or by the court itself and, when called and examined by the court, may be cross-examined by the several parties to the action or proceeding in such order as the court may direct. When such witness is called and examined by the court, the several parties shall have the same right to object to the questions asked and the evidence adduced as though such witness were called and examined by an adverse party. Whenever the expert or experts so appointed are called to testify, the court may, in its discretion, advise the jury, if there be one, that such expert or experts had been appointed by the court to make the necessary examination and testify as expert witnesses. The court or judge may, at any time before the trial or during the trial, limit the number of expert witnesses to be called by any party.

NEWS NOTES

A Cave-in in a 6-ft. Trench in Los Angeles, on June 23, severely injured a workman caught in the trench.

A Dynamite Explosion on a Government Dredge at Smithsonia, Ala., on the Tennessee River, on June 26, killed seven men.

A Boardwalk Collapsed dropping 50 persons into the river at Stag Island, on July 1. No one was injured. The walk led over water to a dock.

An 80,000-lb. Blast was shot at Colton, Calif., on July 4, according to press dispatches. The blast was for the purpose of getting out limestone for cement.

A Ship's Gangplank Broke in Charlestown, Mass., on June 30 and fell upon the crowd of people below, killing one man and injuring four others just before the White Star Liner "Cimric" sailed for Liverpool.

Broken Tackle dropped 40 tons of steel turbine casing to the deck of the new Argentine battleship "Rivadivia" at the docks of the Fore River Shipbuilding Co., Quincy, Mass., on June 29, according to press dispatches.

A Canadian Pacific Steamer Grounded on the rocks at Bad Neighbor Island, near Cove Island, on the night of July 1, in a fog. Sister ships speedily reached the "Assiniboia," 5000-ton flagship of the railway fleet, and commanded by Commodore McConnel. Early on July 3 her cargo was taken off by lighters and the steamer floated. She proceeded under her own steam to Port McNicoll.

A Large Flywheel Burst, shutting down for 24 hr. the plant of the Union Brewery, St. Louis, Mo., at 1.25 a.m., on June 29, with damage amounting to about $50,000. A segment of the 24-ft. 8-ton flywheel shot through the 4-in. concrete ceiling, breaking the ammonia pipes in the condensing room above. At the same time, steam pipes were broken, shutting down the plant. It is said that the speed of the wheel increased from 40 r.p.m., normal speed, to several times this speed before bursting.

A Loose Rock in a Deep Shaft of Section 3, Bayonne, N. J., of the Passaic Valley sewer, now under construction, fell to the bottom, killing five of a gang of thirteen muckers, at 9 p.m., July 3. The shaft was at one end of the siphon under Newark Bay; the other end is in Newark. The inside diameter of the shaft after the 18-in. concrete lining has been placed is to be 12 ft. It will be 250 ft. deep, and had been sunk to a depth of 230 ft. at the time of the accident. The shaft was through firm rock and was not timbered. The main piece which fell weighed about 5 tons, and dropped from a point in the wall about 75 ft. above the bottom. There was no blasting going on at the time and no other shock is reported. The fall was probably caused by intersecting seams in the rock. According to the New York & New Jersey Constructing Co., New York City, the shaft is inspected or scaled for loose rock every day, and had been thus inspected by the foreman one hour before the slippage. The large size of the loose section probably accounted for its not being discovered.

A Gas Explosion in the New Water-Works Intake Tunnel, Milwaukee, Wis., injured 21 workmen of a gang of 30, at 7.30 a.m., Monday, June 29. No work had been done in the tunnel on the previous day, which accounted for the large accumulation of gas. The explosion was probably caused by a lighted match or a spark struck by a drill. The tunnel was not damaged.

The tunnel, described in "Eng. News," July 24, 1913, p. 155, and June 18, 1914, p. 1334, is of brick lined with concrete and has a diameter of 12 ft. It will extend into Lake Michigan a distance of 4000 ft. to a crib from which four lines of 6-ft. cast-iron water mains will extend to a point 2500 ft. out in the lake where the water is 60 ft. deep. Work is going forward rapidly. The tunnel is divided into compartments and it was in the farthest out of these, 2050 ft. from the shore shaft, that the explosion occurred. The work is not done under compressed air, although an emergency air-lock has been provided. The crib was to have been sunk in place June 29.

The City-Manager Plan for Seattle, Wash., was defeated by a heavy majority at a popular election held on June 30.

The Proposed Naval Dry Dock at Norfolk, Va., which was in the preliminary Naval Bill before this Congress, has been rejected in the final bill. Provision was made in the bill for the rental from the Union Iron Works of a new dry dock to be built at San Francisco and to be capable of taking care of any boat which can pass the Panama Canal.

Pavement Construction by Municipal Day Labor has been decided upon in Kalamazoo, Mich. The city council has decided to purchase a complete plant for building concrete and brick pavements. It is expected to construct about $20,000 worth of concrete pavements and a $10,000 reinforced-concrete bridge by municipal labor during the present season.

A Municipal Paving Plant is soon to be put in operation by the Canadian city of Edmonton, Alta. It is planned to lay about 100,000 sq.yd. of asphalt and concrete pavements during the present season by municipal day labor. The plant will be operated in competition with contractors. The entire paving program for the present season involves an expenditure of $1,500,000.

Petty Grafting in the Public Works Department of Detroit, Mich., has been unearthed by the new Commissioner of Public Works, George H. Fenkell, M. Am. Soc. C. E., and 25 teamsters have been discharged. These teamsters are alleged to have pocketed thousands of dollars from the sale of old wood paving blocks, which were the property of the city. The blocks were sold for fire wood.

A Comprehensive Sewerage Scheme for North Toronto, Ont., has been recommended by the Commissioner of Public Works. R. C. Harris, of Toronto, of which North Toronto has become a part. The approximate cost of the proposed combined system is $4,114,256, including many miles of large trunk sewers and a sewage-disposal plant. The estimated cost of a sep-

ar[illegible] system of sanitary and storm water sewers for the [illegible] was [illegible].

Railway Terminals in Foreign Cities are to be investigated by the new Railway Terminals Commission, of Chicago, which [illegible] is composed of representatives of the city and of [illegible] organizations. The party is expected to include some of the engineers who are members of [illegible] whose work is related to the problem of [illegible] the railway terminals and facilities. The party will sail from New York on July 11 and is expected to return in September.

Concrete Road Construction in the United States, according to the "Bulletin on Concrete Roads" published by the Universal Portland Cement Co., has increased from 364,000 sq.yd. [illegible] to 19,[illegible] sq.yd. which will be laid during the season of 1914. This area to be laid in 1914 is nearly double that laid in 1913, and over ten times the yardage laid in 1911. The yardage for 1914, above noted, which doubtless includes city streets as well as country roads paved with concrete, would be equivalent, if laid in one stretch, to a roadway 12 ft. wide and 2740 miles long.

Instruction in Public Health, Sanitary Science and Preventive Medicine. A committee to study and to report to the university authorities what courses in these subjects should be given in the College of Physicians and Surgeons and in other departments of Columbia University has been appointed by President Butler. Among other members the committee embraces E. R. A. Seligman, Professor of Political Economy, Chairman of the Committee; D. D. Jackson, Assistant Professor of Civil Engineering; Dr. Hans Zinsser, Professor of Bacteriology; and Dr. Walter Bensel, formerly Sanitary Superintendent of the New York City Health Department; Robert E. Chaddock, Associate Professor of Statistics.

Sanitary Protection of the Water-Supply of Interstate Vessels.—The U. S. Treasury Department has amended the interstate quarantine regulations administered by the Public Health Service by adding the following paragraph governing the water supply of ships:

No person undertaking to furnish water for drinking or cooking purposes to any vessel in any harbor of the United States, intending to clear for some port within some other state or territory of the United States or the District of Columbia, shall furnish for such purpose water taken from the waters of any harbor, or from any other place where it has been or may have been contaminated by sewer discharges. Any person violating this regulation will be liable to a penalty of not more than $[illegible] or imprisonment for not more than one year, or both, at the discretion of the United States District Court.

The Purchase of the Property of the Spring Valley Water Co. of San Francisco, may be effected by agreement with the company instead of by condemnation. A valuation of the plant has been completed by M. M. O'Shaughnessy, City Engineer, who states that [illegible] of the property as the city needs for water-supply purposes is worth $[illegible]. It is [illegible] that the officials of the city and the company will agree to submit the question of purchase at this figure to popular vote. If approved by the people, the condemnation proceedings entered upon some time ago will, of course, become unnecessary. We understand that a number of [illegible] engineers have been at work for both sides in preparation for the condemnation proceedings.

A World's Concreting Record. What is believed to be a world's record in mixing and placing concrete for [illegible] of [illegible] was [illegible] on the [illegible] Dam [illegible]. The record is as follows:

[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]

A $200 Prize for the Best Thesis on House Plumbing [illegible] has been offered to the students of the Harvard University and the Massachusetts Institute of Technology. [illegible]

[illegible] must be handed in on or before May 1, 1915. These must be typewritten and three copies furnished. Awards will be made by a committee appointed by Prof. Whipple and Gifford LeClear, Lecturer on the Mechanical Portions of Buildings in the Harvard Department of Architecture. In making the award special consideration will be given to theses based on original investigations.

Sub-Basement Stores or Salesrooms, made practicable by the deep foundations of some of the large store buildings in Chicago, are prohibited by city ordinance as being dangerous (in case of fire) and unsanitary. The ordinance limits the depth to 2[illegible] ft. below the street grade, but one new store building has a sub-basement 40 ft. below the street. The Health Department brought suit against the owners, and after a municipal court judge had decided against the city, the case was appealed to the Illinois Supreme Court, which has rendered a decision upholding the ordinance. It was argued that a fire in a crowded store two floors below the street would be extremely dangerous, while investigation has shown that it is practically impossible to secure adequate ventilation at such depths and in floors occupied by crowds of people. Such floors are liable to be damp, and the employees would have to work continuously under conditions of artificial light and ventilation.

The Eruption of Lassen Peak, Calif., began, May 30 at 5.30 p.m. with an outburst of steam, which, according to Forest Supervisor W. J. Rushing, continued about 10 min., forming a crater in the snow-covered summit above 25x40 ft. and covering the snow for a distance of 300 ft. with dark, wet dust. Geologist J. S. Diller, in a report to the United States Geological Survey, stated that on the following day, at 8 a.m., another eruption occurred, followed on June 8 by a third and heavier one lasting 30 min. In all there were 11 eruptions to June 21. The most violent was at 9 a.m., June 14, which was visible from the Sacramento Valley, nearly 40 mi. away. The eruptions are usually preceded by a complete cessation of escaping steam. By June 20 the crater was 100x100 ft. by about 100 ft. deep. The ejected dust appears to be disintegrated or pulverized dacite and is produced by the pulverizing action of the explosive gases on the rocks through which they escape, and is not the result of the explosive expansion of gases in a liquid lava.

The Relative Importance of Different Seaports of the United States is shown by the statistics in the annual report on Commerce and Navigation for 1913, just issued by the Department of Commerce. The total foreign trade of the United States, including both imports and exports, now amounts to four and one-quarter billion dollars in round numbers, of which about two billion dollars were handled through the port of New York. The second seaport of the United States, however, is now Galveston, through which $[illegible] worth of goods passed last year. New Orleans comes third with $[illegible] worth; Boston fourth with $216,[illegible]; Philadelphia fifth with $17[illegible]; Baltimore sixth with $1[illegible]; San Francisco seventh with $[illegible]; Puget Sound ports eighth $[illegible]; [illegible] Detroit tenth, $[illegible]. In the total foreign trade amounting to $4,2[illegible] last year, the exports exceeded the imports by $[illegible]. The value of manufactured goods exported was more than six times as great as the imports of manufactured goods.

The Salem Conflagration caused the largest loss ever experienced by the Massachusetts Mutual Insurance Companies of New England. The Naumkeag cotton mills, which were in the area swept by the conflagration, were wholly destroyed with a loss of about $[illegible]. Although the area [illegible] was closely covered with dwellings and various business buildings, about one-third of the value destroyed was contained in this one factory plant. [illegible]

PERSONALS

Mr. Merritt Haviland Smith, M. Am. Soc. C. E., recently Deputy Chief Engineer of the Board of Water Supply, City of New York, has been appointed Chief Engineer of the Department of Water Supply, Gas and Electricity, to succeed Mr. I. M. de Varona, M. Am. Soc. C. E., resigned as noted in our issue of last week. Mr. Smith was born in New York City in 1862 and graduated in civil engineering at the Pennsylvania Military college in 1880. For three years he was in the engineering department of the Pittsburgh & Western R.R. on survey and construction work. In 1884 he first became connected with the public works of New York City as a chief-of-party on surveys for the New Croton Aqueduct. Later he served as Assistant Engineer under the

Merritt H. Smith

Resident Engineer in charge of maintenance, repairs and operation of the Old Croton Aqueduct. During 1890 and 1891 he was engaged in engineering work in Florida. Mr. Smith returned to New York City in 1892 as Assistant Engineer of the Finance Department of the City, and the following year he was appointed Engineer on Repairing and Principal Assistant Engineer of the Department. During the Spanish-American War he received nine months' leave of absence from his city office, and during this period he served as Captain and Major of the First United States Volunteer Engineers in the Porto Rico campaign. He was appointed Department Engineer, Board of Water Supply, City of New York in 1906, and had charge of the Southern Aqueduct Department. Subsequently he was promoted to be Deputy Chief Engineer.

Mr. W. C. Lyon has resigned as Chief Inspector of the Rockford, Ill., city water department and will move with his family to Florida.

Mr. Frank Ernst has resigned as Sewer Commissioner of Moundsville, W. Va., to accept a position with the engineering department of the Wabash R.R.

Mr. J. R. Kearney, former Superintendent of Transportation of the Baltimore & Ohio R. R., has been promoted to be General Superintendent of Transportation.

Mr. Alan P. Wilson has been appointed Western Sales Manager of the Blaw Steel Construction Co., of Pittsburgh, Penn., with headquarters in the Peoples Gas Bldg., Chicago, Ill.

Mr. Thomas E. Murray, F. Am. Inst. E. E., Vice-President of the New York Edison Co., New York City, has been elected a member of the Board of Trustees of the Emigrant Industrial Savings Bank, New York.

Mr. E. W. Bemis has been appointed by Mayor Harrison, of Chicago, to succeed Mr. George Weston, M. Am. Soc. C. E., as the city's representative on the Board of Supervising Engineers which is in charge of the local traction affairs.

Mr. E. M. Scofield, M. Am. Soc. C. E., President of the Scofield Engineering Co., Philadelphia, Penn., has been appointed Vice-President of the Texas Southern Electric Co., owning and operating public utilities in Southern Texas.

Mr. George A. Greenslade has resigned as General Superintendent in charge of terracing operations on the east bank of Culebra Cut, Panama Canal, and is now in New Orleans, La. He expects to return to the Canal Zone to engage in private business.

Mr. James E. Taussig, recently Superintendent of Transportation of the Texas & Pacific Ry., Dallas, Tex., has been promoted to be General Superintendent to succeed Mr. J. W. Everman, resigned, as noted eleswhere in these columns. Mr. Taussig's former position as Superintendent of Transportation has been abolished.

Prof. R. J. Potts, head of the department of highway engineering at the Agricultural and Mechanical College of Texas, has resigned, effective Aug. 1. Prof. Potts has formed a partnership with Messrs. Charles E. Moore, of Waco, Tex., and W. Fred Smith, of Dallas, Tex., under the firm name of the Potts-Moore Gravel Co., with offices at Waco.

Mr. Charles H. Motsett, former Superintendent of the New York division of the New York, New Haven & Hartford R.R., is now Superintendent of the Panama R.R., with headquarters at Colon, Panama. Before going to the New York, New Haven & Hartford R. R. in 1908 most of his experience was with the Chicago, Rock Island & Pacific Ry.

Mr. W. W. Follett, M. Am. Soc. C. E., for the past 12 years Consulting Engineer of the International Boundary Commission, United States and Mexico, has resigned. His present address in 414 El Paso and Southwestern Bldg., El Paso, Tex. Mr. Follett received the honorary degree of Master of Engineering at the recent commencement of the University of Michigan.

Mr. Chas. E. Weidman, former Chief of the Division of Fire Protection of the Panama Canal Zone, has left the Isthmus for his former home in Lincoln, Neb., where he was Chief of the city fire department before going to Panama in 1905. Since Apr. 15 of the present year, the Division of Fire Protection, Panama Canal Zone, has been merged with that of Police and Prisons.

Mr. L. H. Shoemaker, M. Am. Soc. C. E., recently Engineer in charge of design, American Bridge Co., Pittsburgh, Penn., has been appointed Division Engineer of the Pittsburgh division of the company, succeeding Mr. Richard Khuen, Jr., M. Am. Soc. C. E., transferred to the erecting department. Mr. Shoemaker graduated from the University of Michigan in 1897. He joined the staff of the American Bridge Co. in 1901 as an Estimating Engineer.

Mr. H. G. Hamett has been appointed Chairman and Mr. William Hutton, Jr., Secretary of a Harbor Commission, recently appointed by the Mayor of the City of Troy, N. Y. The Commission contemplates the development of the harbor, the construction of warehouses, concrete bulkheads, slips and piers; all made necessary to care for the expected increase in traffic when the New York State Barge Canal is completed. It is expected that a Consulting Engineer and a Traffic Manager will be appointed to act with the Commission.

Mr. John W. Everman, formerly General Superintendent of the Texas & Pacific Ry., Dallas, Tex., has been promoted to be Vice-President and General Manager of the St. Louis & Southwestern Ry. of Texas, with headquarters at Tyler, Tex., succeeding Mr. W. N. Neff, resigned. Mr. Everman is a native of Philadelphia, Penn., where he graduated from the public high school in 1876. For two years he was engaged in mining work in Venezuela. In 1879 he entered the service of the Pennsylvania R.R. The following year he joined the operating staff of the Texas & Pacific Ry.

Lieut. George R. Goethals, Corps of Engineers, U. S. A., who has been in charge of the building of the Panama Canal Fortifications, under the immediate supervision of his father, Col. Geo. W. Goethals, Chief Engineer of the Panama Canal, has completed his work on the Isthmus and has been detailed to the Military Academy at West Point as Instructor. The fortifications have been constructed with the utmost secrecy, and probably no engineers but Col. Goethals and his son are familiar with all the works. The forts on the Atlantic side have batteries of 14-in. guns, 12-in. mortars and 6-in. guns, while those on the Pacific side have in addition one 16-in. gun, according to press dispatches.

Messrs. Frederic H. Fay, Chas. M. Spofford, M.'s Am. Soc. C. E., and Sturgis H. Thorndike announce the formation of the firm of Fay, Spofford & Thorndike, Consulting Engineers, [illegible] Boylston St., Boston, Mass. Mr. Fay has been Division Engineer of the Department of Public Works of Boston for several years past and has had charge of the design, construction and maintenance of all city bridges and the operation of the city ferries. Prof. Spofford is Hayward Professor of civil engineering at the Massachusetts Institute of Technology, and he will continue in this capacity, devoting only a portion of his time to the new firm. Mr. Thorndike until recently was Designing Engineer of the Department of Public Works of Boston under Mr. Fay. The new firm will specialize in the design of structures in steel and masonry, including superstructure and foundation, and river and harbor work.

Mr. I. M. de Varona, M. Am. Soc. C. E., whose resignation as Chief Engineer of the Department of Water Supply, Gas and Electricity was noted in our personal columns of last week, has been connected with the Greater New York water-works for nearly 32 years. His first work was in Brooklyn in 1882, when he was placed in entire charge of the surveys for the extension of the works from Rockville Center to Massapequa, the purchase of the property, the preparation of plans and specifications, and later the construction of the water-works with the exception of the Millburn reservoir. In 1894 he was appointed Engineer of Water Supply of the City of Brooklyn, and as such he was in charge of the collection, extension, distribution and pumping systems. For eight years following Mr. de Verona was actively interested in developing the driven well system, which is the chief source of the Brooklyn water supply. This work was continued until the total underground supply was increased from 17 millions to 130 million gallons daily. In 1897 he established the Prospect laboratory for the study of the prevention of water pollution, one of the pioneer plants of its kind. In 1902 he was promoted to be Chief Engineer in charge of the entire water-works system of Brooklyn, and in this capacity entirely remodeled the distribution system of Brooklyn, thereby adding greatly to the effectiveness of the fire protection of the city. Mr. de Varona planned and constructed the first infiltration gallery system for collecting the subsurface water on Long Island in 1903. He designed the high-pressure auxiliary fire protection system of Brooklyn in 1904, and subsequently, in 1905, when similar systems were planned for the other boroughs of Greater New York, Mr. de Varona was appointed Chief Engineer of Water Supply of the Boroughs of Manhattan, the Bronx, Queens and Richmond, continuing in charge at Brooklyn as Acting Chief Engineer. In 1910 the operation of the water-works of all the boroughs was consolidated into the Department of Water Supply, Gas and Electricity, and Mr. de Varona was appointed Chief Engineer. Some of his most notable work here has been in water waste prevention. It is estimated that the systematic campaign conducted under his direction has saved the city nearly 100 millions of gallons per day out of a total of 500 millions per day. The cost of operating the system has been reduced $1,000,000 per annum. The more important works recently prepared have been the plan of the utilization of the Catskill supply to [illegible] the boroughs, the design of the connections between the Catskill and existing systems in the Boroughs of Manhattan, The Bronx and Brooklyn, the by-passing of the Central Park reservoirs, the tunnel under the Harlem River, so as to make an additional connection between the Bronx and Manhattan, the study of the [illegible] of the Croton [illegible] to provide adequate [illegible] in Manhattan and The Bronx, a tabulated statement of the present and prospective [illegible] of the water supply system of Greater New York, referred to the period between 1913 and [illegible], the present worth of the whole water-supply system of Greater New York, and the study of the reorganization of the Bureau of Water Supply on a functional basis. Mr. de Varona has also been consulted on water works problems by numerous [illegible].

OBITUARY

[illegible]

[illegible]

[illegible] June 28, aged 29 years. He was the son of George N. Orcutt, Assistant to the President of the Erie R.R.

George T. McLaughlin, a contractor, of Pittsburgh, Penn., was drowned in the Allegheny River, near Hulton, on June 28. He was swimming near his summer home.

Alexander Stewart, General Superintendent of Motive Power and Equipment of the Southern Ry., Washington, D. C., died June 28, in Paris, France. He was 46 years old. He was born in Fort Wayne, Ind., and began his railway experience as a machinist's apprentice on the Union Pacific R.R. He was promoted in the service of the Union Pacific to be Master Mechanic at Cheyenne, Wyo. In 1903 he left the West to enter the employ of the Southern Ry. as Division Master Mechanic at Knoxville, Tenn. He was successively promoted to the highest office in the mechanical department within three years. He was a delegate to the International Railway Congress at Berne, Switzerland, in 1910, and was prominent in the railway mechanical associations.

VOLUME 72 JULY 16, 1914 NUMBER 3

The 174th Street Arch under the Grand Boulevard and Concourse, Borough of The Bronx, New York City

By Jacob M. Friedland.*

The Grand Boulevard and Concourse is a parkway 182 ft. wide, extending from the southern end of Franz Sigel Park, at East 151st St., New York City, north to Mosholu Parkway, near Van Cortland Park. It is laid out on the crest of a practically unbroken ridge which separates the Jerome Ave. valley from the Webster Ave. valley.

The law which authorizes the Concourse provides for the construction of not more than fifteen "Transverse Roads" under it. These enable the crosstown trolley cars to cross the Concourse without endangering the fast north and south automobile traffic, and at the same time they eliminate some very steep grades for the general east and west traffic. In the typical Transverse Road, of which seven have been constructed so far, the inclined approaches to the Concourse are 35 ft. wide, and the transverse road has a 36-ft. roadway and two 4.5 sidewalks. A single row of columns in the center of the roadway carries a line of girders, which girders and the sidewalls, in turn, support transverse 24-in. I-beams with concrete jack-arches which carry the roadway above them.

The 174th St. Transverse Road differs entirely from the typical road described above. The Concourse at this point is so high above the adjacent streets that the inclined approaches were omitted. The road, therefore, simply permits 174th St. to run into Featherbed Lane, which leads, by way of Aqueduct Ave., to the Washington Bridge over the Harlem River. The underlying material being a compact limestone, it was decided to build a masonry (concrete) arch, which was more economical than a steel structure, and permitted a street 80 ft. wide without obstructions in the roadway.

Among the noteworthy peculiarities of this arch may be mentioned (1) the sharp skew; (2) the deep fill over the arch; (3) the design of the spandrel walls; and (4) the architectural treatment of the faces of the arch and of the spandrel walls.

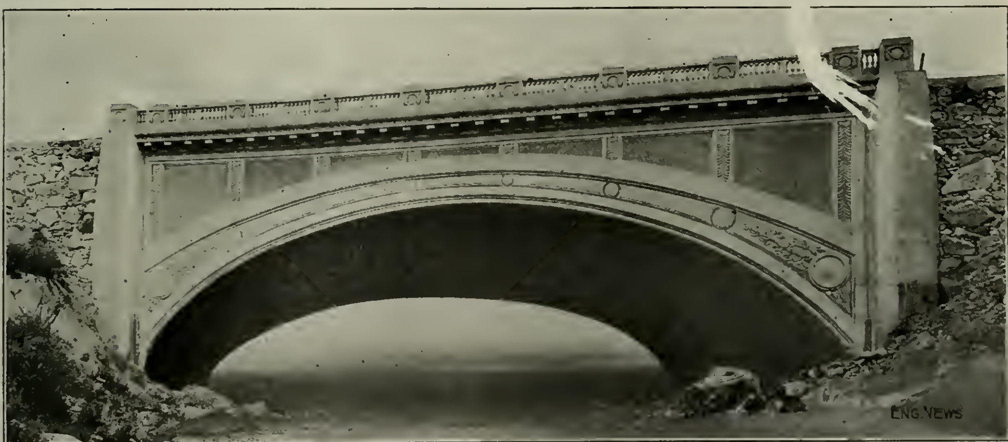

Fig. 1. Concrete Skew Arch Carrying the Grand Concourse over 174th St., Borough of the Bronx, New York City

Sharp Skew—The east face makes an angle of about 52.5° with the axis of 174th St. (instead of 90°), and the west face makes an angle of about 58.5° with it: so that while 174th St. is only 80 ft. wide, the span, measured along the east face, is 100.93 ft. (See Fig. 2.) The arch barrel, with a length of over 221 ft. along the center line of 174th St., is divided by expansion joints into six sections of 36.84 ft. each, in order to make sure that the arch would have an effective span of about 100 ft. Without these joints the arch would probably have acted as an arch with a span of 80 ft., while near the faces there would be overhanging ends in which the stresses are practically incomputable, and which would have been endangered by the extra weight of the spandrel walls and by the outward thrust at their foot.

Deep Fill—In order to pass the sewers on the Con-

*664 E. 170th St., New York City.

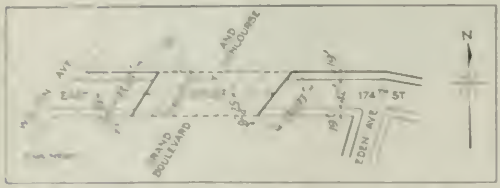

FIG. 2. PLAN OF 174TH ST. CROSSING OF THE GRAND BOULEVARD, THE BRONX, NEW YORK

enough for the extra load due to the spandrel walls, the balustrade, and the earth thrust.

SPANDREL WALLS—A spandrel wall acting as a retaining wall of the gravity type, or of the usual plain or buttressed reinforced types, with heel weighted down by earth backing, was not considered safe here. The intensity and the uncertain nature of the stresses near the faces, the downward slope of the top of the arch toward the face on account of the skew, and the fact that high compressive stresses, added to the outward thrust, might

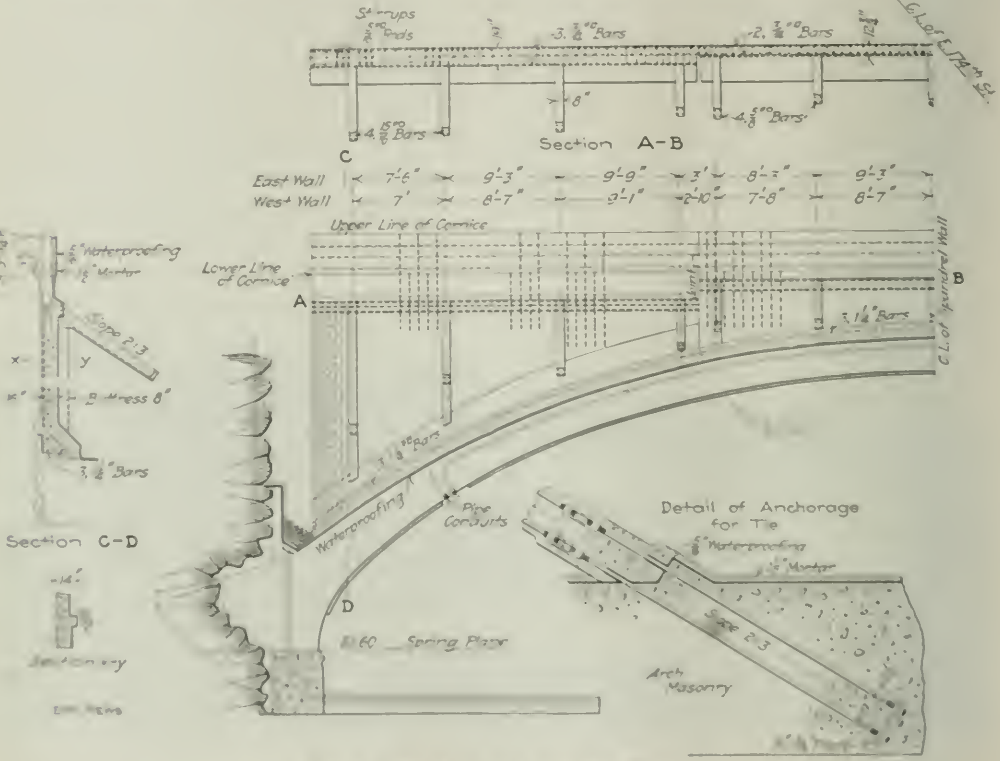

FIG. 3. DETAILS OF THE SPANDREL WALL

hauled across the arch, the fill over the crown had to be 9.5 ft. deep. While the heavy fill simplified the computations by reducing the disturbing effect of the live-load unit stresses on the dead-load unit stresses, it required an arch with big dimensions, and with correspondingly high retaining walls over them.

Excepting 9 ft. from either face, the arch is of plain masonry of a 1:2:5 mixture, in which the native stone was used. It has a span of 160 ft. and a rise of 22.1 ft. The crown is 5.67 ft. thick and the spring 8 ft., requiring 8 in. of extra thickness on the soffit to produce the parallel effect. Contraction and expansion effects based on a drop in temperature of 60° F. produce extreme fiber stresses of 240 lb. per sq.in. compression, and negligible tension at the critical point. For 9 ft. from either face, the arch is made 6 in. thicker and is reinforced with twisted I-bars, square bars to make it strong

cause the architectural features of the face to spall off. All these considerations made it desirable to obviate high toe stresses under the wall, as well as outward thrusts on the face of the arch. Computations also showed that shrinkage and arch deflection would cause the wall to crack unless expansion joints were provided, both in the wall and between the wall and the arch extrados.

Fig. 3 shows the wall that satisfies the requirements. Below the cornice the wall is a reinforced-concrete slab from 10 to 16 in. thick, with vertical reinforcement. Nearly the entire earth pressure against it is transmitted to the horizontal beam, placed at a height slightly above the resultant of the earth pressure, so as to leave a very small outward thrust at the base. The horizontal beams in turn react against the inclined ties which are anchored back into the arch far enough from the face, or into bulge-pads. These ties are in planes perpendicular to the face,

FIGS. 4-5. VIEWS SHOWING THE SPANDREL WALL DETAIL DURING AND AFTER CONSTRUCTION

and not parallel to 174th St., and for this reason some of them do not strike the arch barrel at all.

The vertical component of the stress in the inclined

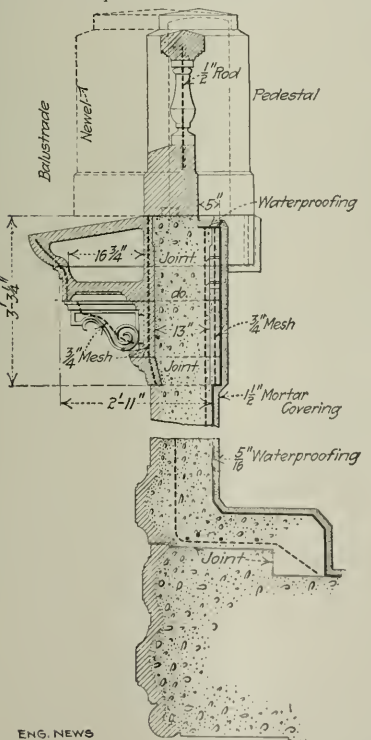

FIG. 6. DETAILS OF CORNICE, 174TH ST. ARCH, NEW YORK CITY

ties is taken up at the wall by concrete posts cast integral with the wall slab, and is distributed evenly over the 2-ft. width of face arch, which is thickened and specially reinforced to carry the additional load.

On top of the wall slab, and forming an integral part of the wall, rests the cornice, which is 3 ft. 3¼ in. high. (Fig. 6.) It consists of four courses of cast concrete blocks having cellular spaces directly over the wall slab. running clear through the four courses, and permitting the reinforcing bars from the slab beneath to pass through to the uppermost block. The cellular spaces were filled with concrete to key the whole firmly together. Enough reinforcement was provided to make the whole act as a reinforced-concrete beam, resisting the moment

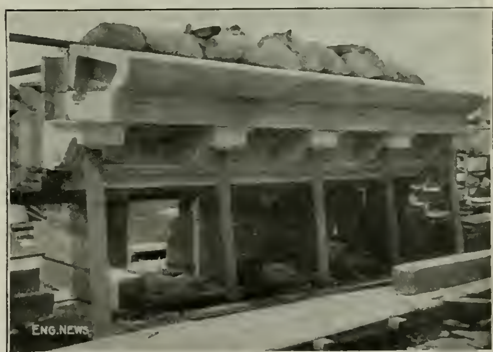

FIG. 7. CORNICE BLOCKS IN PLACE

due to the earth pressure behind, and to the overhang on the face.

ARCHITECTURAL TREATMENT—As shown by Fig. 1, the architectural treatment is elaborate. The balustrade and the cornice consist of cast concrete elements (Figs. 6-7), the balustrades having no less than eight different elements, and the cornice not less than five, not counting right- and left-hand elements and special blocks near the ends. The oblong foliated panels on the wall and the panels carrying the branches and the large end medallions are inset, and were anchored with dowels after the rest of the work had been completed and the face forms removed.

None of the face fillets corresponds to a line of the arch behind it, nor do the long foliated panels coincide

with the location of the ties which hold the wall. Yet so skillfully has the work been carried out that the free joint which separates the wall from the arch cannot be detected, while only parts of the vertical joints in the wall can be seen where they are not concealed by the foliated panels. The latter joints are carried clear through the cornice and balustrade.

Fig. 8 shows the arch centering. The specifications required it to be so smooth and rigid as not to leave any marks either of the wood, or of deflection or irregularity, on the completed arch. The centering was used three times, being lowered, shifted and wedged up twice.

To get the correct position of the many fillets, tablets, etc., on the face, the whole face was carefully plotted on stretched paper to a scale of 1 in. = 1 ft., and the coördinates of the several fillets and tablets scaled and reduced to a table of elevations. These were afterwards marked on the face forms, and the strips and tablet molds fastened to the backing board in accordance with these marks.

The fact that the face concrete, from 2 to 3 in. thick, is different from the backing concrete, and the thinness of the entire wall made it necessary to carry up the rear

FIG. 8. CENTERING FOR SKEW ARCH, 174TH ST. AND GRAND CONCOURSE, NEW YORK CITY

forms just ahead of the concreting, so that, while the rear boards were being nailed on, the face concrete having the consistency of stiff mortar was deposited with shovels against the face forms, and right behind it was dumped the wet concrete. Considering the complications the results are remarkably satisfactory, and, unlike other works of the same nature, the actual face looks even better than the "picture."

SPECIFICATIONS—The following are abstracts from the specifications:

[illegible]

[illegible]

[illegible]

[illegible]

ment mortar similar in color to the face concrete, calked hard and neatly finished with flat-faced calking chisel.

Panel ornamentation of the arch faces, and the foliated panel ornaments of the spandrel walls shall be cast separately, to fit recesses left for them in the concrete. Each piece shall be anchored with at least three anchors made either of aluminum, or of steel, hot galvanized all over. No part of these ornaments shall be thinner than 2 in. unless so shown on the detail drawings.

PERSONNEL—The arch was designed in the Bureau of Design of the Borough President's office, Borough of The Bronx, Richard H. Gillespie, Chief Engineer, and Charles Gartensteig, Engineer of Design. F. F. McDowell was Assistant Engineer in charge of construction. Handy Bros. were the contractors, and the concrete work was carried out by the Londino Construction Co., as subcontractors, to whom most of the credit is due for the success of the work.

※

Scoop Car for Handling Railway Slides

A special car has been designed for clearing railway track of material brought down by landslides or by the caving of a tunnel roof. In such cases the use of a steam shovel may be impracticable, due to the difficulty or impossibility of getting cars within its reach to receive the material excavated, while in many cases the slide may contain large masses of rock difficult to handle. The scoop car is forced ahead into the material till the scoop is full, and the car is then hauled rapidly to some convenient point for dumping. These cars are in use on the Norfolk & Western R.R. and a few other roads, and one of them is shown in the accompanying cuts.

The car is 40 ft. long over the end sills, or 51 ft. 8 in. over all; it is equipped with a 20-ton crane mounted over the center of the front truck, and having a fixed reach of 12 ft. A double-drum hoisting engine with cylinders $8\frac{1}{4}$x10 in. operates the 1-in. hoisting cable and the $\frac{3}{4}$-in. swinging cable, the latter passing around a bull-ring at the foot of the mast. There is a vertical boiler 8x$4\frac{1}{2}$ ft., with the necessary coal space and water tanks. To the hoisting block is attached a swing beam having a chain at each end. The scoop is about 12 ft. long, 7 ft. 8 in. wide and 3 ft. 4 in. deep inside, with a nominal capacity of 10 cu.yd., and it is fitted with heavy teeth on the edge. The car and its machinery weigh about 90,500 lb., which the scoop increases by 16,000 lb.

When excavating, the front of the scoop is attached to the chain hooks and its rear end is held by a pin and backed against a heavy bumper in front of the car, the bumper being supported by inclined braces from the sills. When the scoop is loaded, its front end is raised clear, and the car is run out. At the dumping point, the scoop is lowered upon the rails, with a timber or metal block under one side (as in Fig. 2). The chains are then detached from the end and hitched to lugs on the bottom of one side, so that the scoop can be tilted and emptied, as in Fig. 1.

The use of this car is said to result in considerable saving of time and expense by reason of its being able to handle quantities of loose rocks much too large to be removed by hand. The following example of the work done is from a report by H. C. Weller, Superintendent of the General Western Division of the N. & W. R.R.

We have had occasion to use the scoop car for the purpose

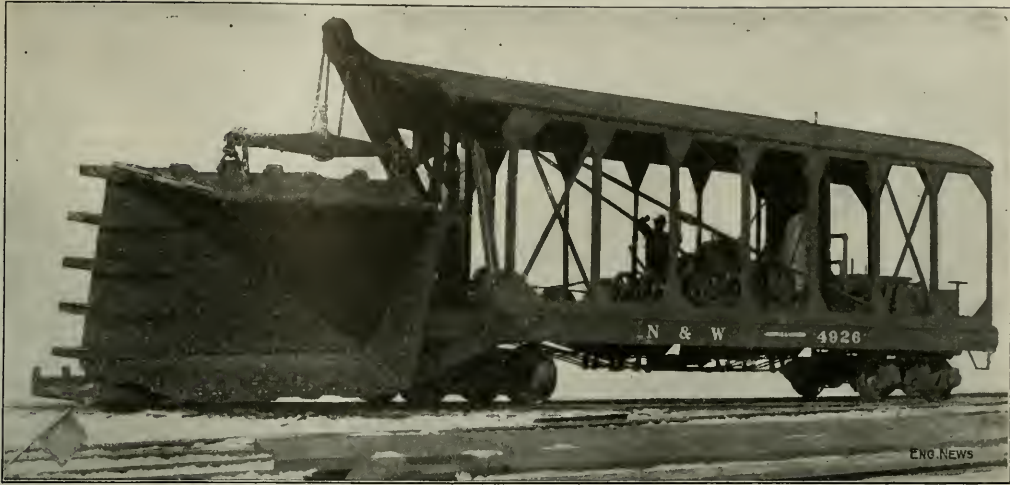

Fig. 1. Scoop Car for Clearing Slides; Norfolk & Western R.R.

(The 10-yd. scoop is shown in the dumped position.)

of moving slides on new westbound main track east of Sycamore. We had a slide at that point approximately 110 ft. in length and 5 ft. deep, or a total of approximately 800 cu.yd. of material to move. It required 10 hr. with the scoop car to move this and convey it from 100 to 150 ft. from the point of the slide. Our labor cost for handling the above quantity of material, which consisted of dirt and rock, amounted to $182, including work-train cost, etc., which is 22.7c. per cu.yd. On occasions when it has been necessary to use the scoop car for handling slides it has proved very satisfactory.

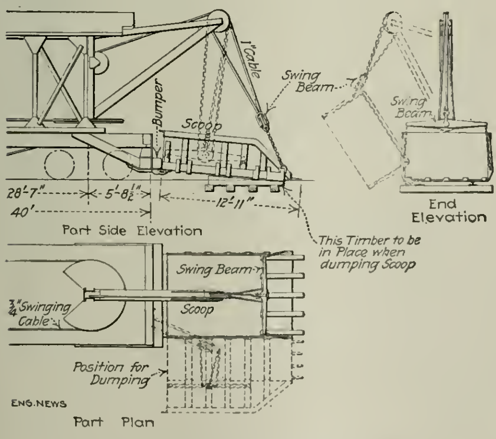

Fig. 2. Front End of Scoop Car, Showing Attachments When Excavating and Dumping

This scoop car has been designed and patented by L. E. Johnson, President of the Norfolk & Western R.R., at Roanoke, Va., and we are indebted to him for photographs and other information.

Preventing Escape of Natural Gas While Drilling for gas or oil is a subject given considerable study by the United States Bureau of Mines, and the result published in Technical Paper 68, dated 1914. Practically all wells are drilled under contract. The contracts are usually lax, to allow for the variable conditions. Drilling contractors are apt to be inclined to disregard the interests of the owner, and to devote their energy to "making hole," i.e., to drilling to a maximum depth in the shortest time and with the least cost. The suspension of work to examine the tightness of casing, or to case off water or gas, is not viewed favorably by the contractor.

The investigation of the Bureau was conducted in the Cushing field, in Creek County, Oklahoma. The method of drilling here is similar to that employed in all Eastern and Northern oilfields, and is called the "dry-hole" method of cable-tool drilling, as the hole is drilled with practically all water cased out. Only enough water is used to keep the drillings slushed out, so that the drill bit strikes the rock at the bottom and the bailer can pick up the drillings and clean the hole. In the Cushing field, the main producing sand, both of oil and gas, is the "Wheeler sand," at 2200 ft. below the surface. The average time required to drill a well to this sand is about 50 days. The hole is usually started 18 in. in diameter; 16-in. casing is set to a depth of 20 to 60 ft., from which point the hole is carried down with a diameter of 16 in. to a depth of 500 to 600 ft., where 12½-in. casing is set. It is necessary to set 10-in. casing at about 800 ft., and 8-in. casing at a depth of about 1200 ft. From 1200 ft. is is usually possible to drill open holes to the top of the Wheeler sand, when 6⅝-in. casing is placed. With this method, the gas waste runs into millions of cu.ft. per day. To give instances, on Apr. 10, 1913, a well was drilled into the Wheeler sand and allowed to go wild for four days, i.e., the drillers left the well without sealing it. The gas wasted daily through an 8-in. open hole was 37,000,000 cu.ft. Its roar could be heard two miles away. This well was shut off on Apr. 17, after some 250,000,000 cu.ft. of gas had been wasted. Nearby, at about the same time, gas was struck at about 520 ft. in a 10-in. hole, and 30,000,000 cu.ft. of gas escaped daily for several days. Other instances are cited, the gas waste in several days. Other instances are cited, the gas waste in some reaching 40,000,000 cu.ft. per day.

The method for conserving gas recommended by the Bureau of Mines is known as the mud-laden fluid method. For purposes of demonstration, a well which had been drilled to a depth of 2140 ft., was filled with mud-laden water and allowed to stand thus for three days, when drilling was resumed. Gas which had been escaping from the well before the introduction of the fluid mud was successfully excluded from the bore-hole. Demonstrations show that the precautions necessary to prevent gas leakage are as follows: (1) Seal gas-bearing stratum as it is encountered, by drilling with the holes full of mud-laden fluid; (2) Set each string of casing with a secure and watertight base, using a long shoe or packer to insure tightness; (3) when casing through a gas-bearing stratum, keep the space between the casing and wall full of mud fluid; (4) place a gate valve on top of the inner string of casing before drilling into any gas-bearing stratum.

A Low-Head Water-Power Plant

SYNOPSIS—At the Coon Rapids hydro-electric plant on the Mississippi River, six miles above Minneapolis, 15,000 hp. will be developed with only 17½-ft. head. The dam is supported on piles with steel sheet-pile cut-off walls beneath. The water level is regulated by large Tainter gates on the dam crest. Vertical turbines are used of 2100 hp., carried on roller bearings at the top of the shaft. Steel-framed forms were used for the dam.

The hydro-electric power plant now under construction on the Mississippi River, at Coon Rapids, six miles north of the city limits of Minneapolis, is of interest on account of the low head to be developed and also on account of the manner in which the power is to be used. The average head is about 17½ ft., and with full flow there will be a development of 15,000 hp. (seven units). There is no storage capacity, however, and at low stages of the river, the flow will be sufficient to develop only about 4400 hp.

Ordinarily, this great variation in power capacity would not be satisfactory for an independent plant, but this plant will be an auxiliary to the larger hydro-electric plant (of 25,000 hp.) at Taylor's Falls, on the St. Croix River, which is owned by the same interests and which supplies current for lighting, traction and general power purposes in both Minneapolis and St. Paul. At present a steam plant of 10,000 hp. is held in reserve at Minneapolis with this station, to take care of peak loads. The Coon Rapids plant will provide for these loads and will enable the steam plant to be shut down, and kept as a reserve for use only when the river is low or in case of any failure at the water-power plant.

In December, 1911, Congress granted the Great Northern Development Co. permission to build a dam at the Coon Creek Rapids to develop water power under a normal head of 16 ft., and the general plans were approved by the War Department in November, 1911. Nothing was accomplished in regard to financing the project, however, and only enough construction work was done to comply with the requirements of the franchise.

In December, 1912, the franchise and property were transferred to R. J. Graf, as trustee, pending the organization of the Northern Mississippi River Power Co., which was completed in March, 1913. Revised plans were approved by the War Department in December, 1912. The franchise required the dam to be completed by Jan. 12, 1914, so that prompt action was necessary. As soon as the property was in the hands of the trustee, a survey party was organized to check the land lines and the flow line of the reservoir, and a superintendent was appointed to organize a construction force and establish a camp. The dam was completed early in January, 1914, and probably the first generator units will be in operation by September.

The general character of the plant is shown by the plan, Fig. 1. There is an island in the river at the site of the dam, and as the left channel is narrower and deeper than the others it was decided to place the power house across this channel, and to build a spillway dam across the wider and shallower channel, the water level being regulated by a row of Tainter gates along the top of the dam, raising the normal water level 7½ ft. above the spillway level. This arrangement is similar to that at the Keokuk Dam, but in the latter case vertically sliding gates are used. The spillway has a discharge capacity of 80,000 cu.ft. per sec.

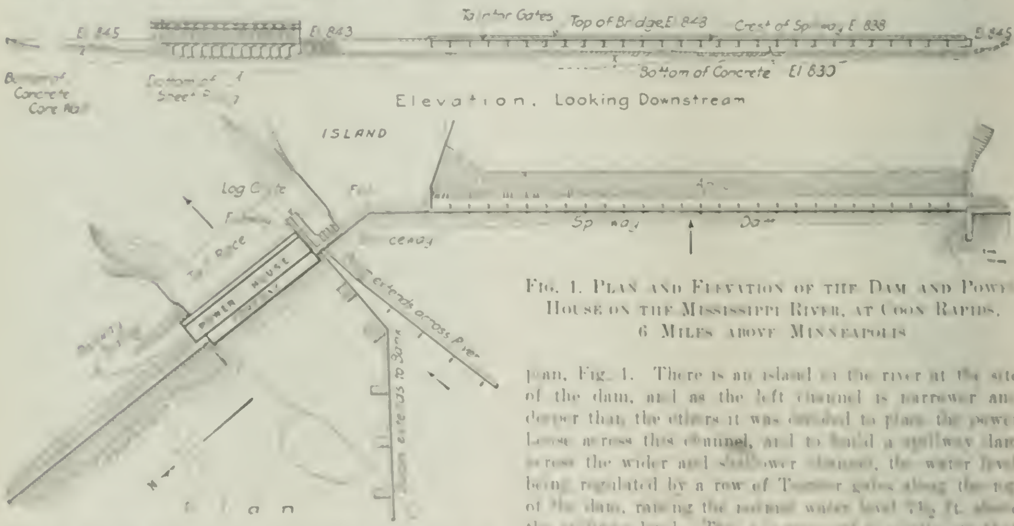

FIG. 1. PLAN AND ELEVATION OF THE DAM AND POWER HOUSE ON THE MISSISSIPPI RIVER, AT COON RAPIDS, 6 MILES ABOVE MINNEAPOLIS

A concrete retaining-dam extends beyond the head of the island from the end of the spillway dam, and between this and the power house are located a fishway, a log chute and four sluice gates. An earth embankment extends from the power house to the high ground on the north bank.

With this arrangement of the power house and spillway, no flood water will be passed through the tail race, and the effective head will be reduced during flood stages only by the backwater from the foot of the island. The spillway dam has a length of about 1000 ft., the retaining dam at the head of the island, 170 ft., the sluices, log chute and fishway, 62 ft., the power house, 255 ft., and the embankment 675 ft., making a total length of 2070 ft.

The entire plant was designed by H. M. Byllesby & Co., consulting engineers, of Chicago. Otto E. Osthoff, Chief Engineer, and W. R. Thompson, Manager of En-

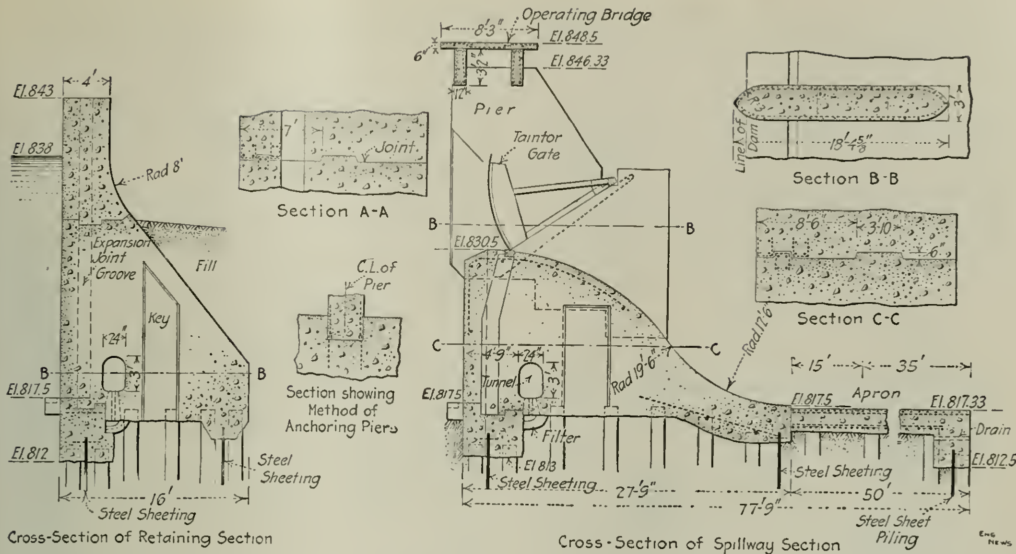

FIG. 2. CROSS-SECTIONS OF DAM, SHOWING THE SPILLWAY SECTION AND RETAINING SECTION

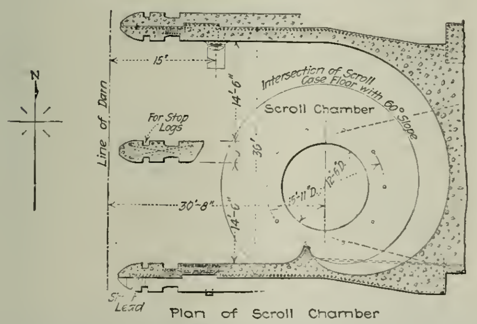

gineering and Construction. It was built by this company's construction force. The design and construction were under the direction of J. W. Link, Hydraulic Engineer; W. T. Walker was Superintendent of Construction, and W. B. Saunders, Resident Engineer.

SPILLWAY DAM

The main dam is built on a deep bed of glacial drift. The Great Northern Development Co. in its preliminary work had made a line of wash borings across the river, approximately on the line of the dam, and other borings above and below the line. These indicated that rock was at too great a depth (not less than 150 ft.) to be reached by the foundations. The Byllesby Co. had additional

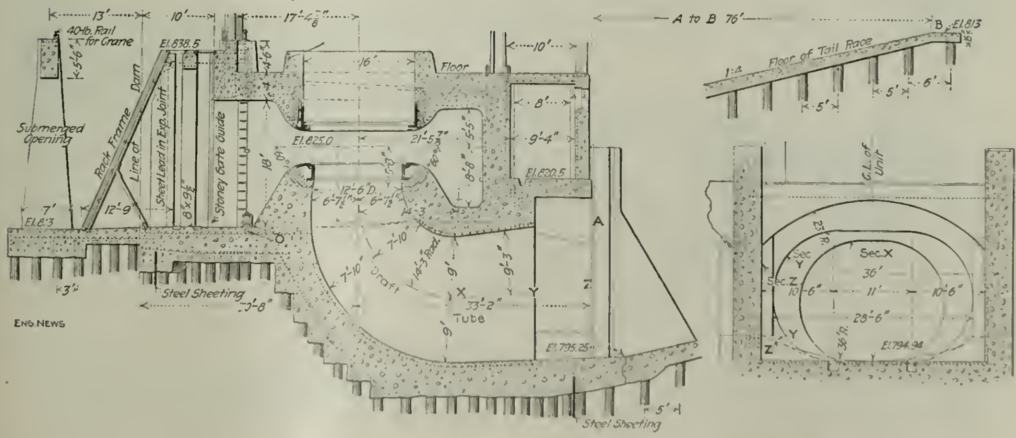

FIG. 3. SECTION THROUGH LOWER PART OF POWER HOUSE; SHOWING THE INTAKE, SCROLL CHAMBER AND DRAFT TUBE OF ONE UNIT

[illegible] borings made by driving 1-in. pipe, the pipe being pulled up after each penetration of about 2 ft. to 3 ft. and the enclosed material removed and preserved. This

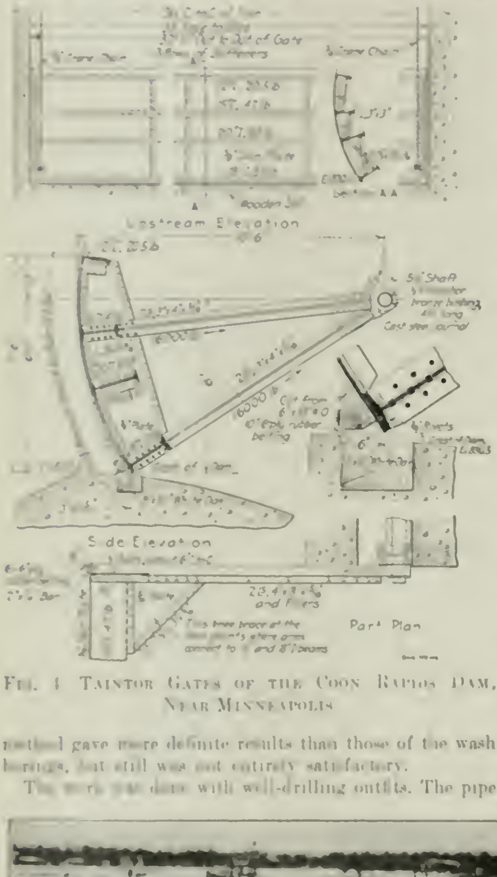

FIG. 1. TAINTOR GATES OF THE COON RAPIDS DAM, NEAR MINNEAPOLIS

method gave more definite results than those of the wash borings, but still was not entirely satisfactory.

The work was done with well-drilling outfits. The pipe drill was fitted with a collar near the upper end to receive the blow from the hammer, the latter having a hole through the center so as to slide on the pipe. The hammer rope passed over a sheave on top of the leads or tower and down to a niggerhead or drum on the engine. The drill runner alternately slackened and tightened the rope on the drum to give the required raising and dropping of the hammer.

The spillway dam is of the section shown in Fig. 2, with a base width of 27 ft. 9 in. and a height of about 12 ft. to the spillway crest. Within it is formed a drainage conduit, with openings in the bottom to a gravel-filled trench or filter, so that any water working beneath the heel can escape without causing upward pressure on the base of the dam. Below the dam is a reinforced-concrete apron 50 ft. wide to prevent scour at the toe.

Along the dam are piers 3 ft. thick, and 36 ft. apart, carrying two lines of reinforced-concrete girders with a deck 8 ft. 3 in. wide, upon which are mounted the hoists for operating the Taintor gates. The boxes for the shafts of these gates are carried in the rear end of the piers. The section of the retaining dam between the power house and the spillway dam, across the head of the island, is also shown in Fig. 2.

The dam is carried on foundation piles, driven to varying depths, and until the penetration indicated a safe bearing value of ten tons per pile. To provide a cutoff against flow of water beneath the dam, there are two lines of steel sheet piling, driven to penetrate at least 5 ft. into material which, from the borings, was assumed to be impervious and which varied in depth below the river bed from about 2 ft. at the south end of the dam to about 25 ft. at other points. A third row is carried under the toe of the apron but this is only 8 ft. deep, being intended to prevent scour beneath the apron by back-wash. For about 200 ft. at the south end where compact material rises to the surface, a trench was cut in this and a concrete cutoff wall built. The power house also has pile foundations, driven to refusal in the com-

[illegible] Taintor gates above the crest, the gates being operated from the concrete deck [illegible]. View looking north from the [illegible] side. The power house is at the farther end [illegible]

pact material, while lines of steel sheeting form the cutoff.

Power House

Fig. 3 is a section through the lower portion of the power house. In the forebay is the wall of the intake, with submerged openings to the screen chamber, which contains the inclined trash racks and has grooves for Stoney gates to close the inlets to the turbines when necessary. The gates will be operated from a hoist on a gantry crane spanning the chamber, one end of the crane-girder having wheels riding on an elevated runway along the wall of the power house, while the other end rests on a leg with wheels riding on a rail laid along the forebay wall.

From the inlet the water enters the scroll chamber, and after passing through the turbine is discharged through the draft-tube, which enlarges from a circular opening 12 ft. 6 in. diameter beneath the turbine to an oval opening 32x23 ft. in the rear wall. This discharges the water into the tail race, which has an inclined floor of concrete on a slope of 1 on 4, rising from elev. 795 (the bottom of the discharge opening) to elev. 813, which is the level of the river bed.

There will be seven vertical-shaft turbines of 2100 hp. each, five of which are to be installed at present. The shafts are suspended from roller bearings above the generators.

Gates

The 28 Taintor gates along the top of the spillway dam are 32 ft. 11 in. long on the face and 7 ft. 6 in. high, with a face radius of 10 ft. 6 in., as shown in Fig. 4. Heavy vertical girders are connected by I-beams to which the faceplates are riveted, and the construction is sufficiently stiff to enable cross-bracing to be eliminated. Each gate weighs about 6½ tons, and is operated by a pair of chains passing over drums mounted on the concrete deck or bridge and arranged for either hand or motor operation. Fig. 5 shows the completed spillway with dam gates in place.

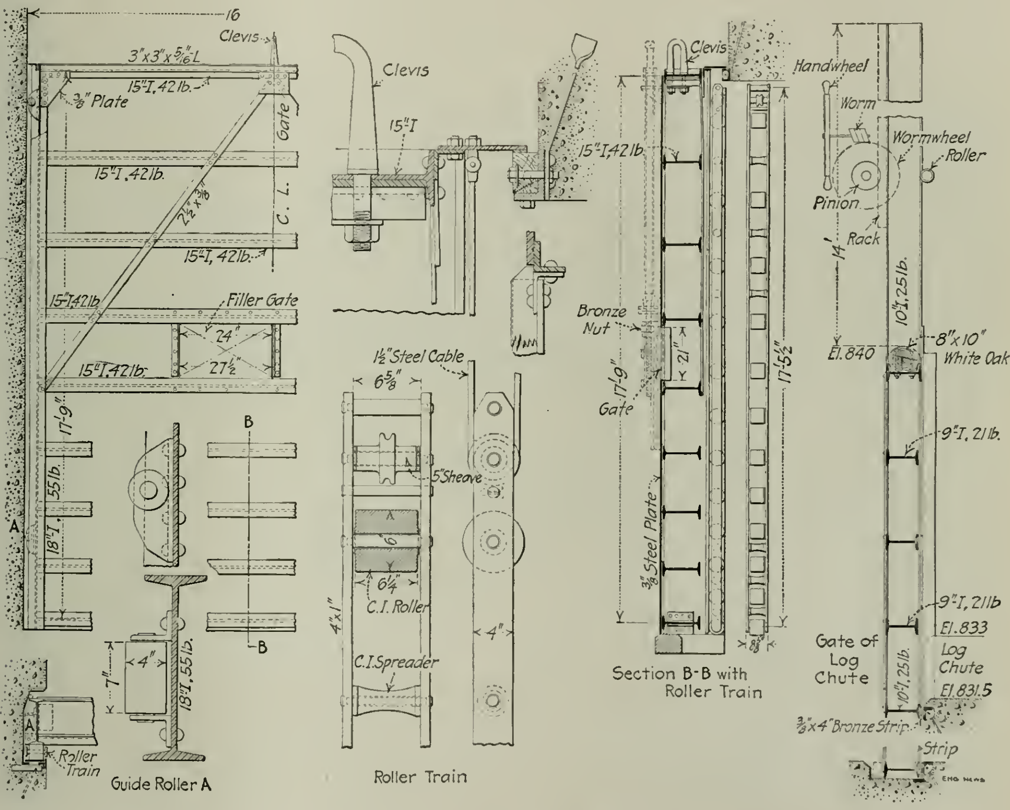

FIG. 6. STONEY GATES FOR THE POWER HOUSE INTAKES, AND GATE FOR THE LOG CHUTE; COON RAPIDS DAM

When closed, the edge of the gate rests on an oak sill on the crest of the dam, and as such sills invariably warp to some extent, a water-tight joint is made by a doubled strip of rubber belting, which is attached to a timber on the face of the gate and projects below it so as to lie against the beveled corner of the sill. The ½-in. clearance at each end of the gate is also sealed with a rubber strip riding against the face of the pier, as shown.

The Stoney gates for the intakes have a framing of 18 in. vertical and 15 in. horizontal I-beams, with ⅜-in. steel plating on the upstream side, Fig. 6. At each

end is a train of rollers riding against a guide in the groove in the masonry. These gates are 15 ft. 2 in. wide (for 14½-ft. openings) and 17 ft. 9 in. high, weighing about 8 tons each. In the center of each is a filler gate 18x21 in., having threaded lugs engaging with vertical operating screws. On the top of each gate is a clevis loop, for the hook of the operating gantry crane.

The four sluice gates are 6 ft. 5½ in. wide and 11 ft. 9 in. high, weighing about 1½ tons each. Each is built of two 8-in. vertical I-beams, with horizontal I-beams between them and with plating on the upstream face. The gate has contact plates of bronze sliding against cast-iron guides in the masonry and has a vertical stem with threaded upper end passing through a revolving nut driven by a hand-operated bevel gear. Fig. 7 shows a section through the sluices. The Stoney gates and sluice-gates close against wood sills when lowered. The sluice gate for the log chute is of similar construction, 10 ft. wide and 9 ft. high, but moves downward instead of upward in opening. It is operated by a rack and pinion at each end, the shaft being driven by a worm gear and hand wheel.

Auxiliary Works

The log chute is 10 ft. wide and the fishway is of the type prescribed by the U. S. Fish Commission. The embankment formed at the north end of the power house has a concrete core wall, with a line of steel sheet piling beneath it. The slope of the embankment on the water side is paved with sacks of concrete laid on 6 in. of broken stone or gravel, as shown in Fig. 7.

There is a considerable amount of logging on the river, and special means are taken to keep the logs away from the forebay and spillway and to guide them to the log chute for passing the dam. Along the north shore and extending across the forebay is a heavy timber boom attached to cribs and forming one side of the approach to the chute. Another floating boom extends from the opposite side of the chute on a diagonal line across the river. The sections of this boom are anchored by chains to pairs of piles having the heads cut off below the water line.

Construction

The Great Northern Ry. and Northern Pacific Ry. are about a mile from the site, and within about half a mile are a public highway and the Minnesota & Northern Ry. This latter is an interurban line to Anoka, operated by gasoline motor cars and freight locomotives.* This line was used for bringing in materials, a spur being built which will be retained permanently. As the construction of the spur was delayed by very cold weather, large quantities of lumber, building materials, and pipe for the water and sewerage systems of the construction camp were hauled by teams and motor trucks from Minneapolis, a distance of 10 or 12 miles. The snow was not deep, and had packed so hard that the roads were good and heavy loads were handled without difficulty.

CAMP—The camp was located on high sandy ground and in a grove of oak trees at the north side of the river. It accommodated a force of about 800 men, besides many women and children. There were about 13 cottages for the accommodation of as many families, besides stores, etc. These were laid out on streets, and provided with water, sewerage (outdoor closets) and electric light. They were frame structures, covered with heavy roofing paper, and were well separated so as to reduce the fire risk. During severe winter weather the bunk houses were heated by hot air furnaces. Other buildings had stoves.

All were temporary buildings, with the exception of the store, the hospital, the superintendent's office, and the bunk houses for the engineers and foremen. A school was provided for the children, and this was used also for moving-picture shows and other entertainments. The water (for domestic and fire purposes) was obtained from an artesian well. The sewage was delivered to an Imhoff tank and the effluent treated by the hypochlorite process.

The spur track from the interurban railway divided into two lines, one being a permanent line which enters

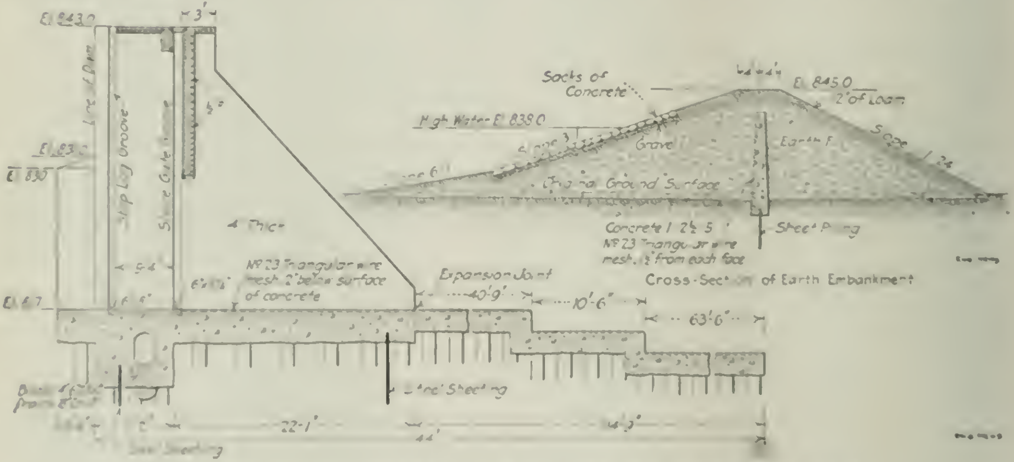

FIG. 7. CROSS-SECTION THROUGH SLUICES AND THROUGH EARTH EMBANKMENT

*"Engineering News," Oct. 16, 1913.

the power house and will serve for handling machinery, etc. The other was a temporary line at a higher elevation and extending on a trestle over the sand and stone bins of the concrete plant, so that these materials could be dumped directly into the bins. From these, it was raised by dump cars on a cable incline for delivery to the mixers. The two 1½-yd. mixers (driven by electric motors) discharged the concrete into 1-yd. dump cars on a narrow-gage track carried across the river on a trestle inside the coffer-dam.

Fig. 8 shows the trestle and construction track, with two inclined chutes for connecting the draft tubes. At the right is the higher trestle for the material track. the light locomotives and concrete cars, and the tracks were connected at frequent intervals by crossovers to facilitate operations. The plant was capable of mixing and placing 1000 cu.yd. of concrete per 24 hr. if necessary. The best records were 516 yd. in a 10-hr. shift, 1006 yd. in 20 working hours, and 72 yd. in one hour.

The concrete was discharged from the two 1½-yd. mixers into steel dump cars of 1-yd. capacity. These were hauled by light locomotives on the construction trestle inside the coffer-dam, the cars being dumped sideways at inclined chutes, as shown in Figs. 9 and 10. These chutes generally delivered the concrete into place, but for the apron of the spillway they delivered it into hoppers

FIG. 8. CONCRETING THE DRAFT TUBES OF THE POWER HOUSE AT THE COON RAPIDS DAM

(The concrete cars are run out on the longer trestle and dumped at hoppers on the inclined chutes. The shorter and higher trestle carries the material track, and has the storage bins beneath it. The draft tubes are 12½ ft. diameter at the upper end and 32x23 ft. at the outlet.)

Fig. 9 shows the work in the first portion of the coffer-dam. Two of the sections of the dam are completed and stripped, and a third is being concreted. The apron also is shown. The grooves in the upper face of the dam are for the piers. The trestle is at the right (upstream side).

This trestle carried three tracks. On the side next to the dam was a standard-gage track on which ran a locomotive crane (Fig. 8) for handling the form work, depositing concrete, setting Taintor gates, etc. Between the rails was laid a third rail to form a track of 3-ft. gage, and another track of 3-ft. gage was laid on the upstream side of the trestle. On these two tracks operated for supplying wheeled carts of 6½ cu.ft. capacity. The trestle track was a little above the level of the top of the dam, and for the upper part of the work the concrete was delivered in dump buckets (on flat cars) which were hoisted by a locomotive crane and dumped into the forms. This crane was used also to handle the forms and other material.

The concrete was mixed 1:2:4 for reinforced work, 1:3:5 for mass work, and 1:2:4 for the floor. All reinforcement was of square twisted bars. A good grade of sand was found adjacent to the work. The stone was crusher-run limestone, hauled from Minneapolis.

The cement store had a capacity of about 7000 barrels. The receiving track was on the outside, and the track for taking cement to the mixers on the inside but at the opposite side of the house, thus facilitating the taking of the cement from the storage space in the order in which it was received.

All the machines in the carpenter shop and blacksmith

Fig. 9. First Portion of Spillway Dam Completed Within the Coffer-Dam

(The construction track and concreting track are on the trestle at the right. The tunnel in the dam is a relief conduit, with overhead drains through the floor to permit the escape of any water under the dam.)

shop, as well as all pumps, etc., were driven by electric motors. As the current generated at this plant is to be sold in Minneapolis, the transmission line was built first (with one circuit of copper cable), in order to get current from the Minneapolis plant for use at the camp and on the construction work.

The construction of the dam was done in two sections, inclosed within timber coffer-dams, consisting of a row of piles 8 ft. apart with waling timbers and a single line of triple-lap sheeting. A bank of earth was deposited against the outside of the sheeting to make it waterproof. For the power-house work, in the deeper channel of the river, the coffer-dam was of stone-filled cribs, held in place by piles.

The deep excavations for the draft tubes extended some 25 ft. below the bed of the river. For the first four tubes the excavation was carried on while the sheeting was being driven and braced, and then the foundation piles were driven. The vibration due to the pile driving, however, caused such pressure and movement of the material that the bracing was distorted and broken and it was difficult to hold the sheeting in place. In fact, it became necessary to replace some of the 12x12-in. timbers with pairs of 15-in. I-beams.

As a result of this experience, for the other three draft tubes the steel sheeting was first driven, and then the foundation piles, these piles being put down to the required elevation by means of followers. When all this was completed, the space to be excavated was inclosed by wood sheeting driven to the full depth, and the bracing was placed as the excavation progressed.

Forms with steel ribs were used for the whole of the dam and Fig. 11 shows the design of these forms, which were in lengths of 54 ft. 8 in. The lagging was of wood, 4 in. thick, held to the ribs by light clamps as shown at X in Fig. 11. To resist the upward pressure of the concrete deposited beneath the lagging, the forms were anchored by rods secured to the foundation piles. The upright posts of the forms were seated in pockets in a concrete shelf along the face of the toe-wall. The piers were built after the dam proper. Fig. 10 shows the forms in place and concrete being deposited.

Four 54-ft. openings in the spillway dam were left to provide ample waterway while the work was being done in the coffer-dam at the power house. These were floored

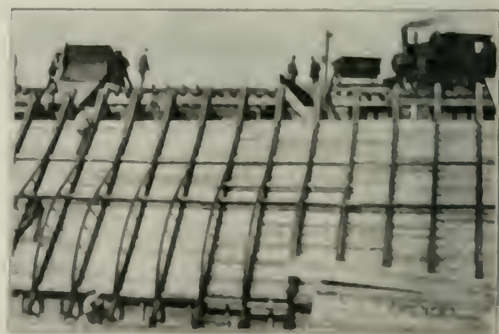

Fig. 10. Concreting the Spillway Section of the Coon Rapids Dam

(The steel ribs of the forms are anchored to the foundation piles to resist the pressure of the concrete, which is [illegible] [illegible] place through the [illegible].)

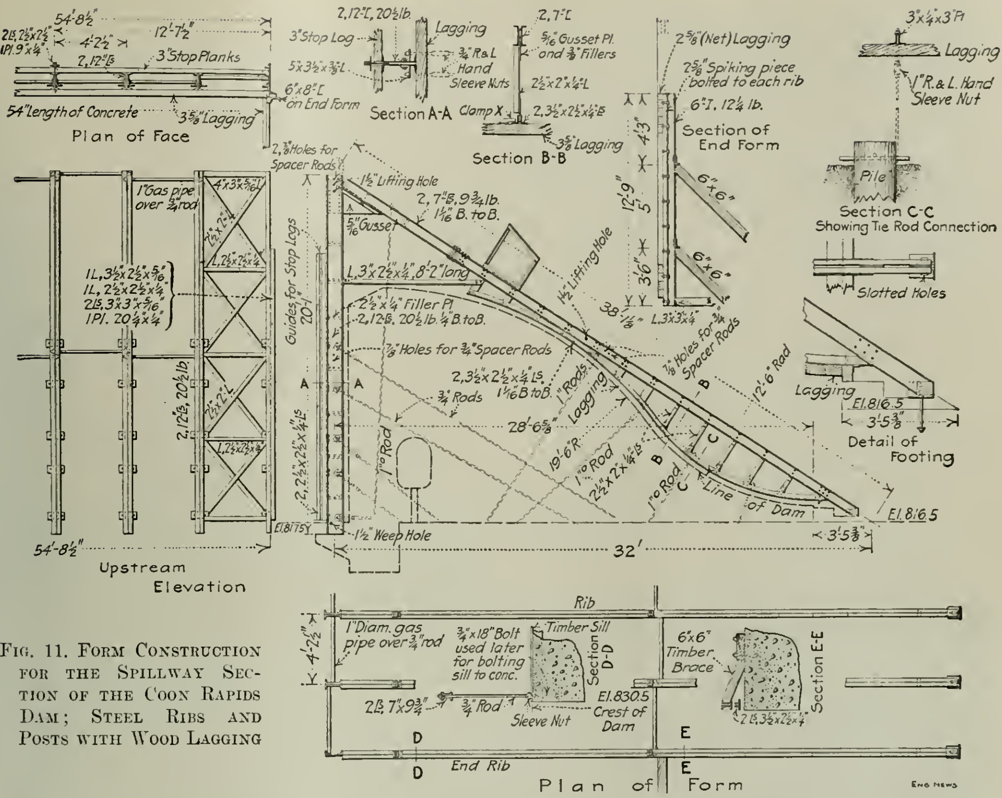

FIG. 11. FORM CONSTRUCTION FOR THE SPILLWAY SECTION OF THE COON RAPIDS DAM; STEEL RIBS AND POSTS WITH WOOD LAGGING

with planking, temporarily, and were finally closed, with the steel forms serving as coffer-dams.

The forms for the scroll cases and draft tubes (Fig. 8) were made in sections, and were collapsible. In this way they were readily assembled and removed.

Sweeping over Macadam and Gravel Roads as a Maintenance Measure

In an article on road maintenance in the *Quarterly Bulletin* of the Philippine Bureau of Public Works, for April, 1914, J. L. Harrison gives some valuable information on road-maintenance problems in the tropics. The following paragraphs advocating the regular sweeping of macadam and gravel roads are particularly interesting, since few states in this country have as thorough or as efficient a maintenance organization and methods as the Philippine Bureau of Public Works.

Mr. Harrison writes: All roads should be swept frequently. This is not because their appearance is thereby improved, though it is undoubtedly true that the neat appearance of a clean right-of-way is very pleasing to the eye; but because of distinct benefits that accrue to the highway itself. All sorts of litter accumulate on an unswept road. That which is not removed either grinds to dust under the wheels of passing vehicles and in this form is mixed with the stone dust and prevents it from properly performing its functions, or washes into the ditches where it causes serious annoyance by collecting about obstructions and causing overflows.

The regular sweeping of a macadam or gravel road also aids in preventing rutting. Many animals instinctively follow paths or trails. Those used in domestic service show very marked tendencies in this direction. If a little fine loose gravel is present, the sweeping of a highway will obliterate wheel tracks. With these out of sight draft animals will make no effort to keep on any particular part of the road surface and a more equal use of the whole of the metalled section will result.

The more evenly wear is distributed the longer a road will last. It may, therefore, be advisable to sweep a road quite often simply to obliterate the wheel tracks. The necessity or advisability of such action will depend on the amount of traffic and the kind of material used for metalling. Roads built of hard rock are less affected by traffic and less aided by this treatment than are roads built of softer stones. Gravel roads seem to be helped more than macadam roads.

Of course, the better the binding qualities of the metalling the more advantage there is to be gained by frequent sweeping for, in the wet season, if the binding quality of the metalling is good, much of the material swept onto the road may bind in and, in that case, not only is rutting prevented but the deficiencies caused by a season's wear may be largely corrected.

Failure of Mixing Flumes for Water-Softening and Filtration Plant, Dallas, Tex.

By N. Werenskiold*

Early in December, 1913, an attempt was made to put the new softening and filtration plant at Dallas, Tex., in operation. Water was turned through the treating and mixing channels leading to the sedimentation basin (Fig. 1), as apparently intended by the plans. Within 27 hr. about 200 ft. out of a little more than 600 ft. of the two basins. The soil when dry has considerable bearing power and cohesion; when saturated with water, as the water side of reservoir embankments will be, it will merely stand on a slope of 2 to 1. It absorbs water readily and holds it well.

Under the engineer's plans, the west basin is to be used for sedimentation, the east basin for filtered water. The raw water was to enter Channel *A* (see large section, Fig. 1) near the division embankment and there be treated with limewater, then to flow to the far end and around the light division wall into Channel *B* and back toward the division embankment. The coagulant was to

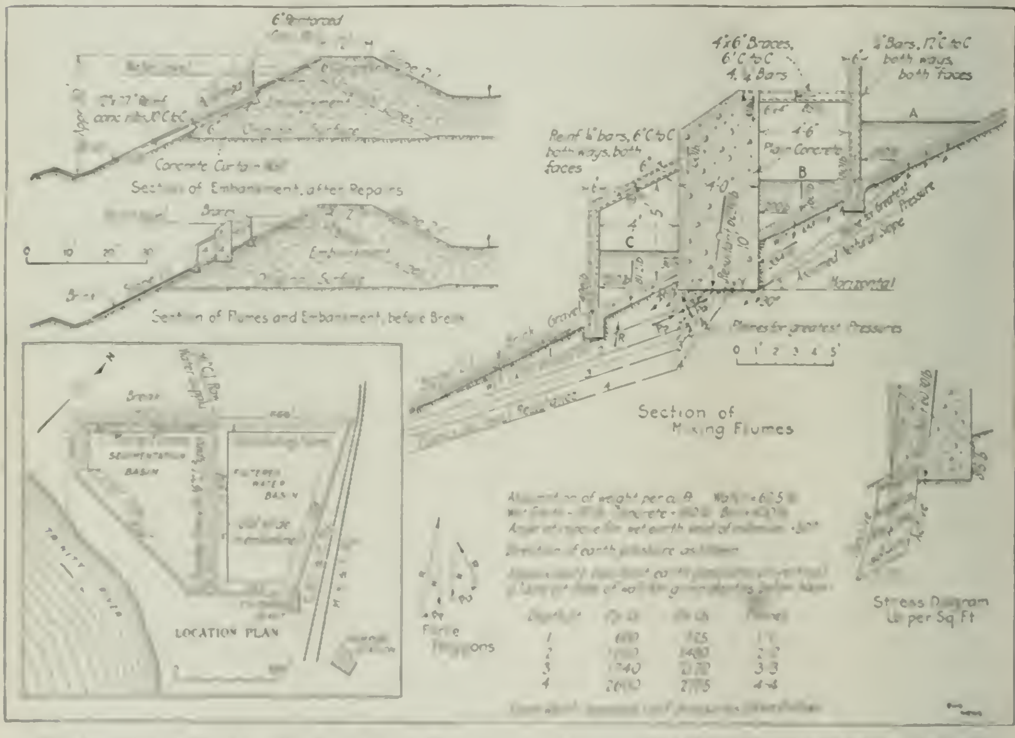

Fig. 1. Mixing Flumes for Filtration Plant, Dallas, Tex., with Sections and Diagrams Showing Cause of Failure and with Location Plan

the flume failed (see Fig. 2). According to the best information obtainable the slope below the flume bulged out and part of the embankment with the heavy walls of the flume slid gradually down, making a rumbling noise and producing fissures felt some distance off. The heavy wall was built on the water slope of a reservoir embankment constructed about 25 years ago.

The two old settling basins (see plan, Fig. 1), each of a capacity of about 65,000,000 gal., were built in and of the alluvial soil in the Trinity River bottom. Their water slopes were protected against wash and wave action by a paving pavement of common brick, made out of the bottom soil, and no other and resting on a little gravel, plastered with cement mortar. Some old pipes in the dividing embankment make it possible to connect be added at the far end. By means of gates the treated water could then be turned either into Flume *C* and flow about 800 ft. through it to the inlet pipe to the sedimentation basin, or it could be turned into a 36-in. cast-iron bypass pipe, resting on top of the decanting or outlet flume, and carried to the small reaction tank of the filter plant. A bypass to avoid both flumes and sedimentation basin had also been provided.

Under the conditions of the filling a lineal foot of the flume and walls would be subject to the approximate forces shown on the section (Fig. 1). The vertical plane of the face of the heavy wall extended below the base may be considered as the back of a retaining wall, which, to prevent the soil from coming out from under the heavy wall, must offer a greater resistance against sliding on the plane of least resistance than the maximum pressure exerted on its back by the earth under the heavy wall.

*City Engineer, Dallas, Tex.

Under assumptions more favorable to the design than any responsible designer would be likely to make, the active and passive earth pressures on the vertical plane have been determined graphically by trials, for different depths, the average unit pressures derived therefrom and shown on a diagram (Fig. 1). The results indicate failure to be reasonably certain.

As a practical demonstration of the need and usefulness of simple theoretical investigations, where precedent, experience or instinct furnish no guide, the design has been a decided success. That only about one-third of the flume failed in one slip may be attributed to varying conditions of the embankment, which had not as yet been saturated by seepage through pavement and construction joints. The embankment could not be expected to support the heavy wall, if there was no water in the channels, after it had been saturated. With water in the basin and corresponding pressures on the slope, the passive pressures would have been far greater; but wave actions might have a disturbing effect.

These extracts were sent to us by Mr. Werenskiold, with the statement that they were taken from the Dallas *Morning News* of Dec. 13, 1913.—EDITOR.]

On Dec. 1, at 1:09 p.m., Mr. Morey, in the presence of the representative of the American Water Softener Co., turned the water into the west basin, through the mixing channel, at the rate of 11,000,000 gal. per day. The water continued to flow into the basin at that rate all that night and until 10:10 a.m. the next day, at which time the accident occurred. There was but one eye-witness to the accident, although Mr. Morey was on the wall ten minutes before the break occurred, and saw then no sign of weakness. When the break occurred a considerable length of the wall seemed to have been undermined at the same instant, the first thing noticed having been the bulging of the slope pavement in a line about 7 ft. below the lower channel; this was followed by the immediate discharge, below the foundation of the wall, of water and mud behind the three parallel walls and the falling flat on its north face of 150 ft. of the collapsed section.

As above stated, the water was brought into the basin through the mixing channel, which was not the proper procedure as, with the basin empty, this would bring pressure on the walls which they were not intended to bear. The basin should have been filled up to nearly the full operating depth through the bypass pipes before permitting the water to flow through the mixing channels, the walls of which were intended merely to divert the course of the water slowly back and forth across the end of the basin to allow it to mix for half an hour with the added chemicals before entering the basin.

FIG. 2. VIEWS OF MIXING FLUME, DALLAS FILTRATION PLANT, LOOKING WEST FROM DIVISION EMBANKMENT
(1) Original flume, immediately after failure. (2) Upper channel (see sections, Fig. 1) reconstructed along length of broken portion.)

In making the repairs the Channels *B* and *C* (see large section, Fig. 1) were bulkheaded off at the break and shortened about 300 ft. The Channel *A* was maintained by supporting the light wall on buttresses and ribs, 10 ft. c. to c., reinforced and provided with curtain walls, as shown by one of the small sections (Fig. 1) and the photograph (Fig. 2). During the latter part of April, the sedimentation basin was partly filled from and through the filtered-water basin by pumping raw water through same, and also through the east end of Flume *C*, which has been converted into a bypass to avoid the use of the other channels in filling. The plant is now (May 11, 1914) reported to have been in successful operation for a few days without any new accidents having been made public. When the water in the sedimentation basin is drawn down some distance below the flume, as it is likely to be sooner or later from some cause, more of the original flume can be expected to take a very natural course down the slope.

CONSULTING ENGINEER'S REPORT ON THE FAILURE

[We reprint herewith extracts from a report on the failure by James H. Fuertes, of New York City, Consulting Engineer on the Dallas water-purification plant.

By filling the basin through the mixing channel the water got through cracks in the old slope pavement and, working down through the gravel under the pavement, brought up against the heavy wall, and backing up, caused excessive pressures.

Had the basin been filled through the bypass there would have been no pressure against the wall when the water was admitted through the mixing channels, and had the backfilling behind the big wall been rammed in, watertight, and the slope paving over this filling been promptly replaced, as directed, the wall would not have failed under the pressures actually exerted, as is shown by the fact that more than two-thirds of the wall still stands intact, and undisturbed even by the violent strains therein caused by the failure of part of it, and that the part that failed is the part from behind which the replacement of the paving was longest delayed.

The portion of the wall that failed is about 200 ft. long, the undermining of this portion displacing and damaging the adjoining sections for a short distance on each side. The failure of the wall destroyed the old slope paving for a corresponding length and for from half to two-thirds the full depth of the slope. The fallen sections of the wall lie nearly flat on this slope, at the middle of the break, and range from this position to a standing position at the two ends of the break; all three diverting walls were destroyed for the width of the break.

There appears to be no further tendency for the walls to slide or move, either as to the uninjured parts, or as to the

poses which fell, and I believe it would be unwise to disturb the fallen pieces on account of the treacherous nature of the soil and its liability to cave, settle and slide when saturated with water and disturbed. I would also hesitate to restore the original slope to this embankment, fearing the reproduction of the conditions that gave so much trouble in the repair of the broken cross-wall.

After stating that it was possible but not advisable to put the filtration plant in operation regardless of the break, although the softening process could not be used until the west basin was made available, Mr. Fuertes discussed repairs to the break in the mixing flume as follows:

It will not be advisable, as above stated, to attempt to replace the slope paving at the break, on the original lines. A treatment similar to that adopted for the old broken cross-wall [not here described.—Ed.] will be required, though it will be less extensive as the caving is much less pronounced and the soil firmer. It will not be feasible, except at considerable cost, to replace all the broken cross-walls, on account of the difficulty of getting proper foundations, but the portions now standing can be utilized by building bulkheads up the slope, each side of the break, and properly connecting the channels across the break in a manner that I will show in drawings which I will prepare after the surveys now in progress are completed. I have made a number of studies for different plans for accomplishing the desired results, and the approximate estimates of cost indicate that an expense in the neighborhood of $5000 will be involved in making the repairs.

We are informed by Mr. Fuertes, under date of June 23, 1914, that the repairs to the flume were carried out in accordance with the general plan outlined in the paragraph last quoted and that the plant has been in operation six weeks. Mr. Fuertes also states that some of the discussions of the break have been "based on the erroneous assumption that the wall which failed was intended to act as a dam or retaining-wall."

Experiments with Screw Spikes and Auxiliary Rail Fastenings; Pennsylvania Lines

Some extensive tests have been made on the Pennsylvania Lines to determine the efficiency of screw spikes as rail fastenings, and to determine also the value of some supplementary devices which are employed in Europe to increase the holding power of screw spikes in the ties. The results were far from satisfactory, although the screw spike has been generally considered as a very efficient rail fastening. Two supplementary fastenings were used: (1) the Thiollier lining,* which is a steel-spring spiral screwed into a thread in the spike hole, in order to compress the wood on which the thread of the screw spike must bear; (2) the Lakhovsky lining, which is a split sleeve inserted in the bored hole and forming a threaded socket for the spike, the sleeve being spread outward against the wood as the spike is screwed home. These linings are shown in the accompanying cut.

The tests were undertaken by W. C. Cushing, Chief Engineer of Maintenance of Way, Pennsylvania Lines (Southwest System) and were in charge of R. D. McKeen and W. H. Wiggins. A resume of the tests and their results has been published in Bulletin No. 165 of the American Railway Engineering Association, and we give herewith a brief summary of the reports. The introductory statement by Mr. Cushing is as follows:

The experiments described were undertaken by the writer to determine if it would be possible to find auxiliary rail fastenings which would serve so as to obtain the full life of a preserved wood tie. It seemed quite doubtful whether the fastenings heretofore proposed would last sufficiently long for the purpose, and suspicions against the screw spike were aroused by the fact that in Europe it was necessary to invent various methods of repairs, such as the wooden screw plug,* the Collet wooden screw trenail, the Thiollier helical lining and the Lakhovsky cast-steel lining.

The methods used in placing these screw spikes were those in common use in France, and the screw spikes used were obtained from France. The trial shows that the screw spikes were too small, the method of placing (without shoulder support for the head) defective, and the problem of rust is still so serious that such kinds of fastenings are rendered ineffective in altogether too short a time.

As a result of these tests, more elaborate tests have been inaugurated on the Pennsylvania R.R. and the Pennsylvania Lines, which are under the charge of a joint committee. The screw spike used is much larger and is the result of study made by the writer. Some of the same difficulties are arising in the new tests, which clearly show that a screw spike is not a successful device for securing rails to wooden ties, unless a successful method of repairs from time to time can be devised, which will enable one to "cure" the screw spike when it becomes loose, which it does inevitably in the course of time in many instances, under heavy traffic and severe conditions.

Indeed, it may be found ultimately that the practice of the Great Western Ry., of England, in using bolts clear through the ties, may be the most successful plan.

A condensation and some direct quotations from the two reports follow:

Ties and Fastenings†

The French screw-spike (Eastern Ry.) used in the test is $5\frac{1}{2}$ in. long under the head, $\frac{1}{2}$ in. diameter at the root of the thread, increased to $\frac{11}{16}$ in. at the shank to insure tightening in the last turn of the spike. The pitch is two threads per inch. The head has a square top tapering from $\frac{3}{4}$ in. to $\frac{5}{8}$ in. for engaging the socket wrench, but this should be made without a taper, as it causes the wrench to lift when the screw is being seated. There were 18,000 of these spikes and the spiral linings. The tie-plates were of the flat-bottom type, 6x9 in., $\frac{11}{16}$ in. thick.

Quoting now from the report:

On hewed ties, the rail seats were adzed by hand, a template being used to insure accuracy. Holes were then bored through the tie with ordinary auger and proper spacing template. The boring may be done by hand or power. In this case a portable air-compressing plant (made for use in bridge riveting) was used, with a wood-boring air motor.

It is necessary to bore the holes entirely through the ties, as the thread-cutting tool could not otherwise be used, due to the accumulation of shavings from it in the bottom of the hole. The holes were then tapped with a special thread-cutting tool furnished by Thiollier. The diameter of the tool at the root of the thread is the same as the diameter of the hole. This operation may be performed by hand, or with a boring machine. In this experiment a compressed-air plant and a heavy air motor were used.

The screw spikes were run down three-fourths of their length with an air-motor wrench and tightened by means of a socket wrench about [illegible] in. long, equipped with an ordinary brace-wheel at the upper end. Two men were required for operating each wrench.

The helical lining is then screwed in the hole by means of a driving mandrel on which the lining is placed, the lining being turned into the tie. Great difficulty was experienced in placing the linings by hand. When the lining was partly in place the friction between it and the wood became so great as to straighten out the bend which engages the mandrel, permitting the latter to turn in the lining. In this event, it became necessary to remove the lining from the hole and replace the bend at the lower end, or replace the lining itself with a new one.

The insertion of the lining was accomplished with difficulty and many were broken during this operation or in replacing the bend so that it might again be driven into the tie. Various attempts were made to overcome this difficulty. Both

*"Engineering News," June 11 and Aug. 13, 1908.

*"Engineering News," Oct. 15, 1914.

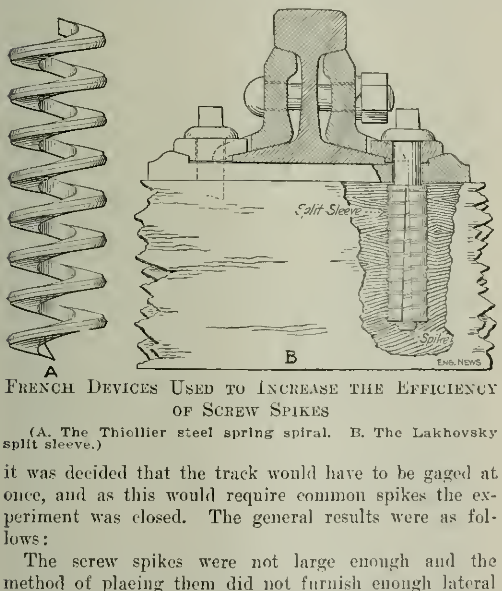
†From the report of W. H. Wiggins, Division Engineer, Pennsylvania Lines, Pittsburgh Division.

the diameter of the hole and the size of the thread were increased, within limits, without much success. A slight increase in the size of the hole, or of the thread-cutting tool, resulted in the lining being too loose and coming out with the screw spike when there was occasion to remove it. A new design of driving tool was finally devised with a shoulder to engage the upper end of the lining, in addition to the one at the lower end. This tool pushed, as well as pulled, the lining into place. Some improvemnt was effected by the use of this tool, but the difficulty was not entirely overcome. It wohld be necessary to use special machinery for executing work of this character.

The cost per tie was \$1.78 with common spikes and \$2.16 with screw spikes and spiral linings. The cost includes the creosoted tie, spikes, tie-plates, linings, adzing, unloading and piling ties, placing ties and surfacing track.

Results of Tests*

The screw spikes and Thiollier helical linings for the spike holes were installed during June to November, 1907, in ties of Kentucky short-leaf pine and red oak, treated with 2½ gal. of creosote per tie (0.33 gal. per cu. ft.). After an inspection of the track in February, 1913,



French Devices Used to Increase the Efficiency of Screw Spikes

(A. The Thiollier steel spring spiral. B. The Lakhovsky split sleeve.)

it was decided that the track would have to be gaged at once, and as this would require common spikes the experiment was closed. The general results were as follows:

The screw spikes were not large enough and the method of placing them did not furnish enough lateral resistance to prevent the widening of the gage. The tie-plates were almost entirely destroyed by rust and many of the screw spikes and Thiollier linings were corroded badly, so that their holding power was destroyed. This condition is supposed to be aggravated by brine dripping from refrigeration cars, as this traffic is heavy.

The holding power of screw spikes is greater than that of the hook spikes commonly used, but the forces tending to loosen them are very great, unless the surface of the track is kept in a high state of perfection. The spikes in loose ties are apt to be quickly loosened by having the threads in the wood destroyed. The above defects having developed in 5½ years, it appears that the fastenings must be adapted for repair work or the full life of creosoted ties cannot be obtained.

There were more loose screws where the tie-plates were used, owing to the corrosion of the plates. The condition of the intermediate screws and tie-plates was very bad, many of the plates having rusted almost entirely away, largely due to the action of the brine from refrigerator cars. The screws in some cases were almost destroyed, their threads having been eaten away, permitting the screws to be lifted out of the ties. Many screws were worn under the head and bent. The bending could be overcome by designing a tie-plate that would support the head of the screw and assist in resisting the lateral thrust of the rail. The tie-plates had all cut into the ties about ¼ in., as had the rails on the ties without plates. Some ties were crushing under the plates. The joint screws and plates were in good condition, but some screws could be raised an inch, due to the tie decaying around the lining.

It is impossible to extract the Thiollier linings or to introduce new spikes with good results. Therefore, the Lakhovsky linings were introduced at the joints, in new holes, to compare them with the other lining. At the time of inspection the joint screws which were installed in 1910 with Lakhovsky linings, clips and larger tie-plates, were giving satisfactory service. They were not bent and all were in good condition with the exception of a few of the linings being loose. At a great many of the joints, the rail, tie and tie-plates seemed to be held firmly to each other, and the entire joint moved up and down under traffic. The joints were all in fairly good line and surface, and this type of fastening seemed to give much better service than the smaller intermediate screws.

CONCLUSIONS: 1. Screw spikes offer a greater resistance to extraction, and will remain tight for a longer period than common spikes if the track is well maintained.

2. By greater holding resistance they tend to reduce creeping of rail and also to prevent the slewing of the ties, but this action is not complete.

3. The screw spikes do not cause the ties to split, as do the common spikes, on account of boring the holes in advance.

4. The cost of maintenance of track for screw spikes is from two to four times as great as for common spikes.

5. Screw spikes cost from two to three times as much to apply as common spikes, and first cost is considerably greater.

6. When screw spikes break, it is impossible to extract the stump from the hole, and when tie-plates are used, it is either impossible or very costly to exchange the tie-plates, so as to allow the proper number of spikes to be used. This might be a very serious matter when the spikes are cut off by a derailment.

7. It is impossible to gage the track which is laid with screw spikes or to straighten rail which is canting on curves, when placed in accordance with the plan used for this experiment.

8. It is impossible to remove screw spikes which have rusted, in order to replace them with new ones.

9. Tie-plates with bosses supporting the heads of the spikes and screws with heads beveled to fit the rail would decrease the lateral thrust and would offer a greater resistance to the rail creeping.

10. Larger tie-plates are required, as those which were used cut into the ties badly.

11. It would seem desirable to fasten the tie-plates to the tie with screw or common spikes so that the sawing action of the plate, under traffic, would be eliminated and reduce the cutting of the plate into the tie. The plate must be held firmly to the tie.

12. Heavier screws are needed, and two screws per rail on the inside should be used on curves to prevent canting and assist in maintaining the gage.

13. The screws should be applied by some mechanical device, so that each screw would bear equally against the rail. By applying screws by hand, equal bearing is not obtained.

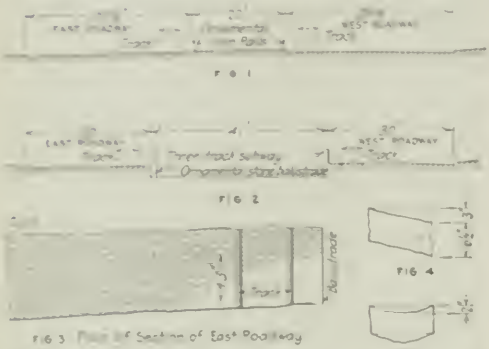
14. Some method should be devised to overcome the effect of the brine from refrigerator cars on track fastenings. The failure of these fastenings was due largely to the corrosion of tie-plates and screws.

*From the report of R. D. McKeon, Assistant Division Engineer, Vandalia R.R.

Remarkable Instance of the Creeping of Asphalt-Block Pavements

By J. H. Gandolfo*

The following description of a creeping pavement that has recently come under the writer's notice, illustrates one of the most advanced cases of such an occurrence of which he has ever heard. The conditions tending to produce the creeping are, however, probably more severe than those ordinarily found on the average city highway.



Plan and Cross-Sections of Upper Broadway, New York City, Showing Creeping of Asphalt-Block Pavement

Upper Broadway, in New York City, is a wide thoroughfare, with two sidewalks, two roadways, and a grass plot in the center, as shown in cross-section in Fig. 1. This avenue runs approximately north and south, the east roadway being used exclusively for northbound traffic and the west roadway for southbound traffic. Along each side of the grass plot is a trolley track (underground conduit system).

The Broadway branch of the subway passes under the avenue, and between 121st Street and 122nd Street the trolley tracks diverge, narrowing the roadways to 30 ft. wide, in order to provide room for the three tracks of the subway, which comes out at 122nd Street in open cut, preparatory to crossing Manhattan Valley on a steel viaduct. The cross-section of Broadway at this point is shown in Fig. 2.

Beginning at 116th Street and extending north to Manhattan Street (125th Street), a distance of [illegible], Broadway is on a down grade of from 1% to [illegible]. The street is paved with sheet asphalt from 116th Street to the south side of 118th Street; but from here on to Manhattan Street the pavement is asphalt blocks. These blocks are [illegible] (5x12-in. surface exposed), on ½-in. cement mortar on a concrete base [illegible] in. thick. This pavement was laid in [illegible].

In addition to the ordinary street traffic of a large city, upper Broadway is subject to a very heavy automobile traffic, as this street is the main artery from the west side of the city leading to the bridge across the Harlem Ship Canal at Spuyten Duyvil. This is the only bridge for vehicles across the river and canal on this side of the city, leading directly north.

Under this heavy traffic, the blocks of the east roadway (the down grade) have at various points moved bodily from their original positions, until the lines of blocks have assumed positions as shown in Fig. 3. There does not seem to be any regularity in this movement, some sections of the avenue being apparently free from any considerable movement, while other sections exhibit a large displacement. This displacement seems to have reached a maximum just north of 122nd Street, where the pavement is now in poor condition. Here the movement of the blocks has reached the astonishing amount of over 4 ft., as shown in Fig. 3.

Creeping of Asphalt-Block Pavement; Patch of New Blocks, Ocean Ave., Brooklyn

The following comparison will give an idea of the singular variation in this movement, the reason for which the writer is at a loss to understand:

118th St. to 120th St., 2 ft.
120th St. to 121st St., very little movement.
121st St. to 122nd St., from 1 ft. 9 in. to 2 ft. 2 in.
Just north of 122nd St., 4 ft. 3 in. (the maximum).
122nd St. to 123rd St., badly creeping, but difficult to follow the lines of the blocks in order to measure the displacement.
123rd St. to 124th St., 1 ft. 10 in. to 2 ft. 2 in.

*[illegible], New York City.

124th St. to 125th St., fairly regular except just north of 124th St., where there is a displacement of 2 ft. 6 in.
125th St. to 126th St., here the roadway widens again, the car tracks being carried in under the viaduct. From here on to Manhattan St. there is very little displacement.

The strain of this movement on individual blocks has been such as to cause them to assume various shapes and dimensions, two maximum cases of deformation being illustrated by Figs. 4 and 5. From these it will be noted that whereas the blocks were originally 5 in. wide, some are now 6½ in. wide, and have been bent and twisted 2 and 3 in. from their original rectangular shape. Of course, it is to be remembered that all these figures are taken from surface measurements, and the blocks are perhaps not so badly distorted deeper down.

Owing to the creeping of the surface of the blocks over the joints between them, combined with the oil drippings from automobiles, the joints are practically obliterated over large areas of the pavement, and it is therefore impossible to follow the lines of the blocks at all on these areas. Indeed, it takes close scrutiny at places to tell the surface from that of the ordinary sheet asphalt.

In making necessary repairs, the blocks have been cut out in the worn portions, and new blocks, 5x2½x12 in., put in place in regular rows perpendicular to the curb, no attempt being made to follow the reversed curve assumed by the old blocks.

There is no way of telling, at present, whether there has been any movement of the concrete base, but it is the writer's opinion that there has not been any very serious displacement. Apparently all the movement has taken place between the blocks and the concrete base; the cause, of course, being the very heavy traffic on a down grade and all in one direction.

On the west roadway, where the traffic is uphill, there has been some little movement at some points, but it is of small amount and very irregular. The general tendency, however, seems to be a movement *up hill,* on this side of the avenue.

Creeping of Asphalt-Block Pavement on Ocean Ave., Brooklyn, N. Y.

Some of our readers will recall a letter published in our columns of Dec. 25, 1913, p. 1315, calling attention to the creeping of the asphalt-block pavement on Ocean Ave., Brooklyn, N. Y., in much the same manner as the pavement described above by Mr. Gandolfo and to a maximum displacement of 4 ft. 6 in. The blocks on Ocean Ave. are 5x2¼x10 in., laid in the same manner as on Broadway. Here also the same reversed curve was noticeable although this avenue is not divided by car tracks.

The accompanying illustration shows a patch of new blocks, placed recently on Ocean Ave. The pavement was put down in the summer of 1910, and is apparently being repaired under the guarantee clause of the contract. In some cases the old blocks are being cut out so as to make a regular-shaped patch, but in many instances the patching is like that shown in the illustration.

This method of failure seems to be common on all the heavily traveled streets in the city which are paved with asphalt blocks. A portion of Flatbush Ave. on a considerable grade shows the same tendency of the blocks to creep or flow *up hill,* as noted by Mr. Gandolfo on Broadway. The cause is the same in all instances—the heavy motor-vehicle traffic always in one direction.

The chart and photograph are particularly interesting as illustrating graphically the strains every pavement surface is subject to. Probably all bituminous surfaces flow or creep in exactly the same manner, but owing to the absence of joints the movement is not so easily detected.

It has been suggested that regularly spaced ribs in the concrete foundation would help to eliminate this trouble. These ribs might be 10 in. wide, perhaps, and come to 1 in. of the surface of the pavement. Over the ribs, special blocks 1 in. thick could be laid, so that the asphalt surface of the pavement would be unbroken.

Slate Beds and other Features of the Devizes Sewage Works

About nine years ago, W. J. Dibdin, of London, England, included slate-contact beds as a part of sewage-treatment works for the small town of Devizes. The following description of the works as they now stand is slightly condensed from notes by Alan J. King, in the *Journal* of the Institution of Municipal and County Engineers (London) for April, 1914.

The plant consists of a total of 18 beds, 8 coarse (2 of these being for storm water), and 10 fine. The coarse beds are 68 ft. long by 48 ft. broad, and are filled with layers of slate about 1 in. apart to a depth of about 4 ft. The storm-water beds are similar, only bigger, being 80 ft. long by 68 ft. broad. These are used when the sewage to be dealt with is more than can be treated by the first six coarse beds, which only happens during very wet weather, and the effluent, after having been through these beds, is allowed to run away without further treatment.

The fine beds are the same size as the coarse beds, and are filled for a depth of about 4 ft. with coke breeze, which has been previously passed through a screen. These beds require renewing about every five years, but the slate beds being once well laid will, with a little attention, last indefinitely. There are also two grit-settling tanks which belonged to a former system, and are now used for allowing the grit to settle after a heavy storm.

The sewage is a dense domestic one about 210,000 [U. S.] gal. per 24 hr., and has the storm water included with it.

Except after heavy rain, when the grit chambers are first brought into use, the sewage is run straight on to the primary slate beds, consecutively, each one taking about 2½ hr. to fill. After standing for about 3 hr., it is run in the same way on to the secondary coke breeze beds and allowed to stand the same time. Then it finally finds its way by a channel over the land immediately below the sewage farm and eventually into a brook.

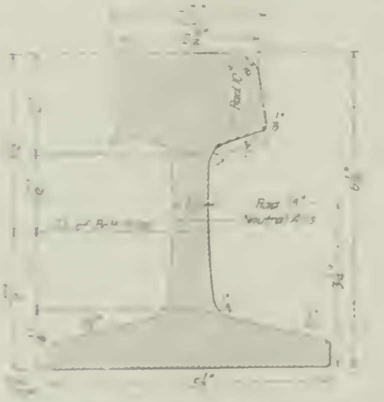
By the time the effluent has come from the fine beds it is very good, so that when not wanted on the land, it is allowed to run straight away into the brook without causing any ill effects.

The whole plant employs 3 men (2 by day, and one for night duty), and the cost is under $1000 per annum. All this amount is practically for wages, and the cost appears to much advantage when compared with the system of pressing the sludge with lime, which was formerly used, and which besides resulting in a large amount of sludge, caused an annual expenditure of nearly $3500.

New 120-lb. Rail Section; Pennsylvania R.R.

The 100-lb. rail, of different sections, has for some years been the maximum size of rail for steam railway track, but the possible necessity and economy of using heavier rails on lines carrying heavy traffic has been suggested from time to time, and the Pennsylvania R.R. has now decided upon trials of a 120-lb. rail. This rail is of an experimental character, and the section is shown in the accompanying cut, while its dimensions are given in tabular form.

In general, the new rail resembles the heavy-base rail (type B) of the American Railway Association sections, but with some important modifications. The proportions of this 120-lb. rail are 41, 22 and 37% for the head, web and base, as compared with 40.2, 19.2 and 40.6% for the 100-lb. A. R. A. (B) rail. The sides of the head have an unusually steep slope (8° as against 3°), while the top of the head has the short radius of 10 in. (as against 12 in.), and corner radii of $\frac{1}{8}$ in. (as against $\frac{5}{16}$ in.). The fishing angles are 18° for the head and 14° for the base, while in most rail sections the angles are uniform and those of the A. R. A. sections are 13°. The height is $6\frac{1}{2}$ in. as against 6 in., but the width of base is the same, since the use of tieplates obviates any necessity of increasing the bearing surface of the rail.



EXPERIMENTAL RAIL OF 120 LB. PER YD., PENNSYLVANIA R.R.

The nearest approach to this new section is the 110-lb. rail of the Lehigh Valley R.R., described in Engineering News, Oct. 24, 1912, and designed for use where heavy grades and sharp curves cause severe conditions of wear. In this case, the height remained 6 in., the same as the A. R. A. (A) section, forming the standard rail, but metal was added to the web and head. This 110-lb. rail (like the new P. R.R. rail) has a 10-in. top radius, instead of the 12-in. of the A. R. A. (A) section. The sides of the head have a slope of 1° (instead of 3°), while the Pennsylvania rail reverts to what has long been an obsolete practice in giving a much greater flare to the head.

This practice was introduced originally on the Lehigh Valley R.R. in fact, some 76-lb. rail of 1881 had a flare of 10°, as against 8° in the new Pennsylvania rail.

120-LB. RAIL, PENNSYLVANIA R.R.

Weight per yard	120 lb.
Height	$6\frac{1}{2}$ in.
Width of base	$5\frac{1}{2}$ in.
Width of head, top	$2\frac{11}{16}$ in.
Width of head, base	$2\frac{31}{32}$ in.
Side of head, slope	8°
Depth of head	2 in.
Depth of web	$1\frac{11}{16}$ in.
Depth of base	$1\frac{3}{16}$ in.
Thickness of web, middle	$\frac{11}{16}$ in.
Height to center of bolt holes	$2\frac{11}{16}$ in.
Radius, top of head	10 in.
Radius, top corners of head	$\frac{1}{8}$ in.
Radius, bottom corners	$\frac{1}{16}$ in.
Radius, fillets	$\frac{1}{2}$ in.
Radius, corners of base	$\frac{1}{16}$ in.
Radius, sides of web	18 in.
Edge of base	Vertical
Fishing angles, top	18°
Fishing angles, bottom	14°
Area of head (41%)	4.84 sq. in.
Area of web (22%)	2.60 sq. in.
Area of base (37%)	4.38 sq. in.
Area, total (100%)	11.82 sq. in.
Moment of inertia	59.20
Section modulus, top	17.77
Section modulus, base	20.00
Neutral axis above center of bolt holes	$\frac{1}{8}$ in.
Ratio of perimeter to area, head	1.13
Ratio of perimeter to area, web	2.88
Ratio of perimeter to area, base	2.77
Ratio of perimeter to area, total	2.12

The flare in the Lehigh Valley rails was reduced to 5° in 1891, and since then it has been limited to 3° to 5° in most rail sections. Presumably the present revival of the flaring head is due in part to considerations of flange wear on curves.

An article describing several so called "frictionless" rails for use on the inside of curves appeared in ENGINEERING NEWS, July 2, 1914, p. 20.

Fire Hazard from Refuse Incinerating Plants, Galveston, Tex.

A brief report on fire dangers from city and private refuse-burning plants at Galveston, Tex., was recently made by the Committee on Fire Prevention of the National Board of Fire Underwriters (135 William St., New York City) following a recent visit by Mr. Goldsmith, one of the committee's engineers. The committee's remarks on the city's plant are substantially as follows:

The city garbage incinerating plant consists of a two-story iron-clad frame building with open first story, adjoining a concrete furnace with concrete stack. Combustion is assisted by oil burners. The chimney is equipped with a spark arrester. The plant has proved to be not well designed to eliminate the fire hazard.

The nearest exposure is a cotton platform 200 ft. to the east, where several minor fires, caused presumably by sparks from the incinerator, have been put out with a bucket of water by the watchmen. These fires were probably due to the poor condition of the spark arrester, the screen of which is rapidly deteriorated by the fumes. It is reported that the clinker is not always wet down by the attendant when it is drawn from the furnace, and this is likewise a possible source of fires.

After commenting on a number of private incinerators, which are of local interest only, the report concludes:

The city is considering the construction of a modern incinerating plant about 300 ft. from pier sheds.

It is believed, from knowledge gained by the inspection of a newly erected plant in Atlanta, Ga., and of the conditions under which other modern plants are operated, that a properly designed and constructed plant which gives complete combustion and provides for safe disposal of the clinker, will introduce no hazard at the proposed location.

The operation of a number of scattered plants should be discontinued, and all burning of refuse confined to a single plant at which the hazards are more carefully safeguarded than it has been in the past; the high winds coupled with large cotton storages in the open render such processes exceptionally hazardous when carelessly handled.

Remarkable Day-Labor Municipal Construction in Minneapolis

By E. M. Richter*

Minneapolis, the first important city in the United States to depart from the contract system on public work, has ordered this year more than $3,500,000 of municipal construction under the day-labor plan, carried out by the city engineering department. Many other cities have adopted the day-labor plan more or less extensively, but none has developed it to the same degree as Minneapolis.

More important items on the 1914 schedule are enumerated in the following tabulation. This does not include the ward street work and sprinkling, in which the day-labor plan also obtains, and many other minor items; the total goes well past the $3,500,000 mark. Further, it does not include betterments in the parks, libraries, hospitals, etc. The latter works are under boards or commissions, independent of the city council under which the engineering department operates. In the boards the contract system is chiefly employed, despite the success claimed for the day-labor plan by its friends.

MINNEAPOLIS PUBLIC WORK TO BE DONE BY DAY LABOR IN 1914

Concrete bridges	$865,000
Paving	750,000
Sewers	680,000
Filtration plant enlargement	200,000
Water-works distribution system	225,000
Sidewalks	150,000
Good roads (special fund)	100,000
Curb and gutter work	100,000
Bassett's Creek improvement	75,000
River harbor wall	65,000
Total	$3,210,000

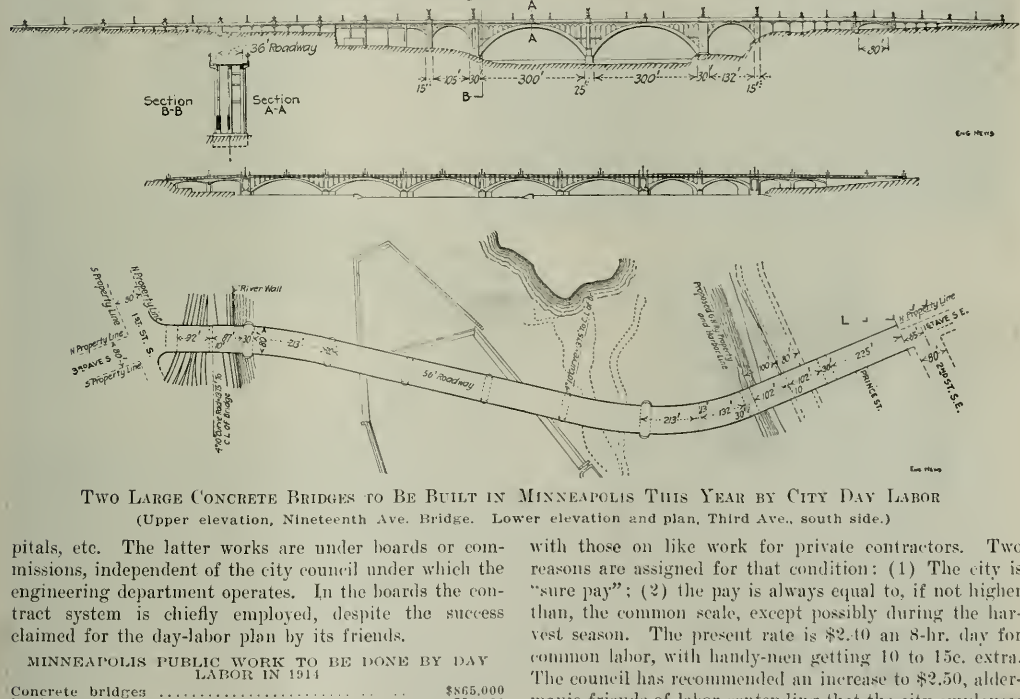
(Minor items add several hundred thousand dollars.)

It is a noteworthy fact that, although permits for private buildings† so far issued in 1914 show a gain of 100% over the same period in 1913, yet the city will be its own largest builder this year. Practically all of this city work has already been put under way and two-thirds of it will be completed by the end of the season. It is carried on under the personal supervision of the city engineer, Frederick W. Cappelen. Nearly 5000 laborers, besides many skilled mechanics, foremen, engineering assistants, etc., are engaged in the work.

Labor Handling

Minneapolis' day-labor work is governed entirely by the municipal civil-service system, inaugurated last July (1913). Common laborers are examined chiefly for physical fitness. Preference is given first to men who have been employed in the same class of work for years by the city, then to American-born men of families—homeowners—over alien labor.

City crews on paving, sewer, water and like construction experience remarkably few changes in comparison with those on like work for private contractors. Two reasons are assigned for that condition: (1) The city is "sure pay"; (2) the pay is always equal to, if not higher than, the common scale, except possibly during the harvest season. The present rate is $2.40 an 8-hr. day for common labor, with handy-men getting 10 to 15c. extra. The council has recommended an increase to $2.50, aldermanic friends of labor contending that the city employees give better service than those of private contractors, even if they are somewhat higher paid; the subject is waiting confirmation by the civil-service commission. Teamsters are receiving $1.75 minimum and $5 maximum.



Two Large Concrete Bridges to Be Built in Minneapolis This Year by City Day Labor
(Upper elevation, Nineteenth Ave. Bridge. Lower elevation and plan, Third Ave., south side.)

Two Large Concrete Bridges

Topping the list of day-labor work is the item of $865,000 for two new ornamental concrete bridges to span the Mississippi River. One is in the heart of the city, at Third Ave. South. The other is at Nineteenth Ave., about a mile below. The former is to have five 213-ft. spans and several shorter spans; the other, two spans of 300 ft. each. The cost estimates, which are thought to be conservative, are $500,000 for the bridge on Third

*Of editorial staff of the "Minneapolis Journal," Minneapolis, Minn.

†Includes a 21-story building already under way, a 27-story building which will be more than half finished by Nov. 1, and numerous other important structures. However, the increase in the permit value is not chargeable to a few unusually large buildings, for the increase in number of permits corresponds to the increase in value.

[illegible]

[illegible]

Ave. (just two blocks from the new postoffice and adjacent to the famous St. Anthony Falls and the great flour-milling district for which Minneapolis is known the world over) and $418,000 for the structure on Nineteenth Ave. Mr. Cappelen and Assistant Bridge Engineer K. Oustad believe, however, that approximately $50,000 may be saved on the construction cost of the latter bridge by using the form material and other equipment used on the Third Ave. bridge.

Sketches of the two bridges are given in the drawing on p. 133.

It may not be amiss to add that the care and maintenance of all the river bridges in Minneapolis are in the hands of the city engineering department.

Paving

Several hundred thousand yards of paving are being laid this year. Creosoted blocks of long-leaf Southern pine are used for the great part of the city paving. The material is popular because there has been practically no difficulty from oozing creosote, buckling and other troubles complained of in some other cities.

A portable asphalt plant, costing about $25,000 equipped, is being operated by the city this year for the first time. It was delivered last fall and used for a small amount of experimental work, which is influencing its use this year. The asphalt crew is putting down principally asphaltic concrete, in most cases as resurfacing on worn brick and granite-block pavement. Orders for this work followed recommendations of Mr. Cappelen that it is both economical and satisfactory.

The general street work is supervised by Assistant City Engineer Ellis R. Dutton, who pays particular attention to paving operations, and is assisted by Street Engineer Benjamin Durham, in charge of grading and other dirt work.

In addition to the large amount of new paving and the ward funds for street work, a special fund of $100,000, proceeds of a "good roads" tax, general in the city, is being used for the improvement of the arterial streets. The ward work, although largely delegated to the street commissioner in each of the thirteen districts, is superintended by Walter Walsh of the city engineer's office.

Sewer Construction

New sewer construction, third in importance on the list, embraces plans for some 20 mi. of sewers, extensions and enlargements of the system, estimated at $680,000, all of which will be completed before snow flies, according to City Sewer Engineer Carl J. L. Ilstrup. It includes the digging of sewer tunnels in the sandrock 80 ft. below the surface through the business district, to relieve overtaxed systems in the district and to provide for business buildings with sub-basements extending below the level of the original sewers. The biggest single sewer project under way is the 10-ft. trunk on Thirty-eighth Street, which is being extended across the southern section of the city from the river at the east limits to the lakes district on the west border, a distance of nearly five miles.

Increased Water Supply

Improvements in the water-works department for 1914 may reach $500,000. Enlargement of the new mechanical filter plant on Columbia Heights just over the north boundary of the city, now in its second year of operation, will increase the capacity from 48,000,000 gal. to about 64,000,000 daily. An additional coagulation basin has just been put into commission to increase the efficiency of the plant, and four additional filter beds (making a total of 16) will be finished about midsummer. William N. Jones, formerly connected with the engineering corps of the Cincinnati filtration plant, in charge of construction here, believes the enlarged plant will be in working order before Sept. 1.

Eighteen miles of water laterals are being laid, under supervision of J. H. McConnell. Demands for extensions were so heavy that the council committee on water-works was forced to limit orders to graded streets, but all these are now to be supplied.

A 50-in. steel main from the filtration plant to the southeastern section of the city, designed to improve pressure conditions in that district, is being laid. The appropriation for it is $45,000.

The water-works extensions are under the supervision of J. Arthur Jensen. The filtration plant is under the superintendency of Lewis I. Birdsall, formerly engaged in a like capacity at Rock Island, Ill.

Valuation and Study of Water Department—With Mr. Birdsall's assistance, City Engineer Cappelen has recently completed a survey of the city water department. A feature of his report is a recommendation that a lime process be adopted to reduce the alkalinity of the city water-supply. The suggestion was approved and the process is to be inaugurated when the plant enlargements are completed.

Street Widening

One of the important items of projected city work is the widening of Seventh St. North, a distance of three blocks in the heart of the business district, and its extension thence in a straight line for about ten blocks through a well built-up residence district. The estimated cost is $567,000. Work will start late this fall or early in the spring, proceedings having already been finally confirmed by the city council.

Bassett's Creek Covering

Bassett's Creek, a stream crossing the northern part of the city, has a history of periodical destructive floods, dating back before the incorporation of Minneapolis. The creek has been a frequent cause of complaint, both for its floods and (in recent years) for its unsanitary condition, produced by rubbish dumps and the like along its banks. The city engineering department is now developing plans to convert the stream into a concrete-enveloped sewer. An appropriation for the construction has been made by the council.

Municipal Harbor Sea-Wall

Finishing the list of regular work committed to the Minneapolis engineering department for execution under the day-labor plan is the item of $65,000 for the erection of a sea-wall, as the first step toward the establishment of municipal steamboat terminals on the river. Minneapolis will be at the head of navigation on the river when the government dam just below the city is completed. The wall is to be started shortly and is likely to be completed this season. Then will follow the building of wharves and warehouses with hoists to elevate the cargoes up the

[illegible] to the level of the proposal municipal belt line to connect with railroads.

Other Work

Additions are being made to the city garbage crematory. A [illegible]-ft. stack is being erected, and preheaters and a forced-draft system are being installed. The incinerators generate steam from which is produced electric current. The station lights and heats the city tuberculosis hospital and workhouse nearby, and operates 200 street arc lights in the surrounding parts of the city.

Day-labor construction is also being used in the erection of warehouses* for the sewer and water departments, at a cost of $25,000. Water-towers have been built for improving the pressure on two elevated areas.

Nor is the story all told. In embryo are projects for a number of municipal ice-houses, a municipal street-railway $1\frac{1}{2}$ mi. long to connect the privately owned city trolley system with the filtration plant, acquisition by the city of the gas plant, and many minor things.

Public Utility Planning by the City Engineer's Office

The last legislature of Minnesota gave the city's engineering and construction organization a noteworthy endorsement by passing an act which authorizes the city to acquire and maintain a union steam-railway passenger terminal. Similarly extensive powers are vested in the city for the purpose of grade-crossing elimination, for which the city may make complete plans.

Union Station Planning

Efforts in the past to secure a union station in Minneapolis by private action had failed. The legislative authorization to the city therefore opens a way to providing a necessary improvement not otherwise obtainable.

The Great Northern Ry. has just erected a $2,000,000 passenger station, opened for traffic early this year. The station of the Chicago, Milwaukee & St. Paul Ry., four blocks distant, serves several other lines; the Minneapolis & St. Louis and Soo lines maintain separate passenger stations.

The legislative act empowers the city to acquire by condemnation necessary ground for trackage. Proceedings have been commenced to obtain title to a strip about [illegible] blocks long and two blocks wide along the river, in the heart of the city, part of which strip is now utilized for tracks into the Great Northern station. Sketches are being drawn in Mr. [illegible]'s office for the station and the entrance trackage. The main feature of the plan is simply to add to the new Hill station an additional wing which will more than double the capacity of the present structure, and to double the station trackage. The city engineer will soon make a tour of Eastern cities to inspect new passenger terminals, prior to the final design.

The most difficult part of the commission was to arrange for all the railways' trackage for both passenger and freight through the district affected. In handling this problem, the aim was to give every railway that enters the city more advantageous facilities than it now enjoys.

Grade-Crossing Elimination

[illegible] several important grade-crossing eliminations are either under way or projected. Detailed plans for all the separate projects under the general movement have been prepared by the city engineer's department, and in most instances two sets, respectively, for track elevation and for depression. In carrying these projects into effect the procedure will be to order separations by ordinance embodying the city engineer's plans and specifications. The cost of the separations must be borne by the railways, even to damages to abutting property, according to the city's contention.

Depression of the H. & D. tracks of the C. M. & St. L. Ry. across the southern section of the city, embracing the construction of a large number of concrete bridges to carry streets over the railway, is well advanced. This is done under plans made by the railway company. For future work, however, the city will make plans. The city is about to bring an action to enforce depression of the main-line tracks of the C. M. & St. P. between Sixth Ave. S. and Thirty-second St. Depression of the Northern Pacific tracks or their removal from their present location in southeast Minneapolis has just been ordered. Proposals covering other lines in the city are pending.

Municipal Water-Power

Plans are being made for a water-power plant and auxiliary steam equipment to produce electrical energy at the new government dam (nearing completion) in the Mississippi River just below the city. A public corporation, organized and operating under special legislative authority, is confident that the Federal War Department will lease to it the dam power rights for the benefit of the University of Minnesota and the cities of St. Paul and Minneapolis. Negotiations with the Federal officials are under way.

Financing the Elwell Law

Funds are now available for practically all the various undertakings listed in the table given at the beginning of this article. The money comes from sales of bonds, levies of special assessments, and the sale of special certificates of indebtedness under the so called Elwell law.

The Elwell law, embodying a plan entirely new in Minnesota, is designed to aid cities in a stage of rapid development to secure public improvements on a provision for extending assessments in twenty annual installments. It can be made to cover the cost of complete improvements on a street, from condemnation of the land, through grading, laying of water mains, sewer, sidewalk, curb and gutter to paving, or any part of the list as the city council may elect. It provides also for payment from general funds of any part up to 33⅓%, and assessment of the remaining expense to the benefiting—not necessarily abutting—property. The validity of the act has been upheld by the state supreme court and many projects are being carried out according to its provisions.

Highway Work in West Virginia—According to recent estimates about $[illegible] is available for highway improvement work in West Virginia during the present season. Of this nearly $[illegible] is to be raised by the sale of county bonds, while the remainder is raised by taxation. The Chief Engineer of the State Highway Department is A. D. [illegible], and Prof. [illegible] Davis of the University of West Virginia, was recently appointed Bridge Engineer. The state [illegible] in the form of [illegible] labor, to be employed under the supervision and in accordance with [illegible] and specifications of the state road bureau.

*[illegible]

San Francisco's Sewer System

By H. W. Shimer and A. J. Cleary*

Previous to 1900, the sewers of San Francisco were extremely discreditable to a city of its size and prominence. As a general rule, they had been laid haphazard as necessity arose, with complete disregard for every engineering principle of design and construction. No attempt had been made to build any one conduit as an integral part of a logical system, nor did the volume of sewage to be disposed of seem to be regarded as an important factor in determining the size. To run the line down hill and reach the bay as soon as possible, apparently was the only method followed. In September, 1899, the Board of Supervisors appointed a commission to investigate, design and report upon a suitable sewer system, and estimate its probable cost. This commission was composed of C. E. Grunsky, Marsden Manson and C. S. Tilton, with Rudolph Hering as Consulting Engineer. The present system, begun in 1904, follows very closely the recommendations of this commission.

Factors for Design

In calculating the requisite size of storm sewers the rainfall rate adopted was 0.598 in. for a continuous storm of one hour duration, while for a period of concentration of 5 min. a maximum rate of 2.16 in. per hr. was presupposed. For intermediate periods the rates were determined empirically.

For a population of 20 per acre a runoff of 30% was assumed, while for districts having 100 residents per acre the runoff was taken as 75%, with an almost uniform increase between these limits. The time element also entered into the calculations, the period necessary for runoff from the most remote portions of the district to reach the conduit and the cumulative quantities that would pass controlling points under the most critical conditions being computed.

At convenient points all water due to storms that exceed 1/4-in. rainfall in 24 hr. is allowed to spill over long overflow weirs and directed through conduits to tidewater. The amount retained in the intercepting sewer is composed of storm water not in excess of the above specified amount, ground-water infiltration, and domestic sewage. Various allowances were made for ground-water infiltration, depending on locality and on the material of which the sewer is built. Usually 0.002 sec.-ft. per acre was assumed. The domestic sewage flow was computed on the basis of an average water consumption of

Fig. 1. Relief Map of Main Sewer System, San Francisco, Calif.

*Assistant City Engineers, City Hall, San Francisco, Calif.

70 gal. per person per 24 hr. This gives an average rate of flow of 0.109 cu.ft. per sec. per 1000 inhabitants. Assuming the maximum flow for short periods to be 50% in excess of the average, the rate for domestic sewage flow is taken at 0.163 cu.ft. per sec. per 1000 inhabitants.

Topographical Features

San Francisco is located at the northern extremity of a peninsula 35 miles in length. The city terminates on the west at the shore of the Pacific Ocean, and on the north and east it is bounded by San Francisco Bay. A spur of the Coast Range divides the area into two main drainage districts, one sloping toward the ocean on the west, the other toward the bay on the east. Many portions of the city being exceedingly hilly both these drainage areas are in turn subdivided. Previous to 1906 there were over 125 sewer outlets along the bay shore. By the recently constructed system the number discharging house sewage will ultimately be reduced to five, with provision for storm-relief outfalls as indicated on Fig. 1.

In determining points of outlet those locations were chosen at which, by reason of strong tidal currents, the maximum dilution of sewage would be obtained. Float observations were made near all of the points in question at flow, ebb and intermediate stages of the tide. It was proven that at the locations selected, when the outfall was extended far out into the bay, no offensive material would be washed back on the land.

As a general rule, the elevation of street surfaces along the water front is city base. Extreme high tide is 1 ft. below city base. Such a height occurs only at a rare combination of wind and flood. Ordinary extreme high tide is 3 ft. below city base and the intercepting sewers are designed to retain their flow without spilling over the weirs of relief outlets at this tidal elevation. Extreme low water is about 12 ft. below city base and inverts of outfall sewers at the bulkhead line are usually from 11 to 13 ft. below city base. As yet, no special devices have been installed at the outfalls, as none have been found necessary.

The ordinary tidal prism of the San Francisco Bay is [illegible] cu.ft., while the maximum flow from the tributary rivers in 6 hours (the duration of an average tidal outflow) is [illegible] cu.ft. This gives a maximum total flow through the Golden Gate of [illegible] cu.ft. in 6 hours. The ultimate maximum sewage flow from the municipal area of San Francisco is estimated at about 215 sec.-ft., which will be reached in 50 years.

Western Drainage Area

Along the ocean beach the breakers are always high and form at a considerable distance from shore. To construct an outfall beyond their influence would be impracticable, so the entire flow of the western drainage area is carried to the northern end of the peninsula through the Sunset District sewer. Storm water will be discharged near Mile Rock and in dry weather house sewage will be pumped from the main intercepting sewer to the Fort Point outfall, where it will empty at ebb tide far out in the channel. The lower portion of the storm sewer will be in tunnel for 1450 ft. Due to protracted litigation before a right-of-way for the outfall could be secured the upper sections were completed first. Work on the tunnel is now being rushed to completion.

For approximately a mile in the higher levels the course of the Sunset District Sewer lies within the drainage area of Lake Merced, whence San Francisco derives a portion of its domestic water-supply. The quality of the water from this source is by no means of the best and to guard against further pollution 24-in. cast-iron pipe with well calked lead joints was used for the sewer within the watershed.

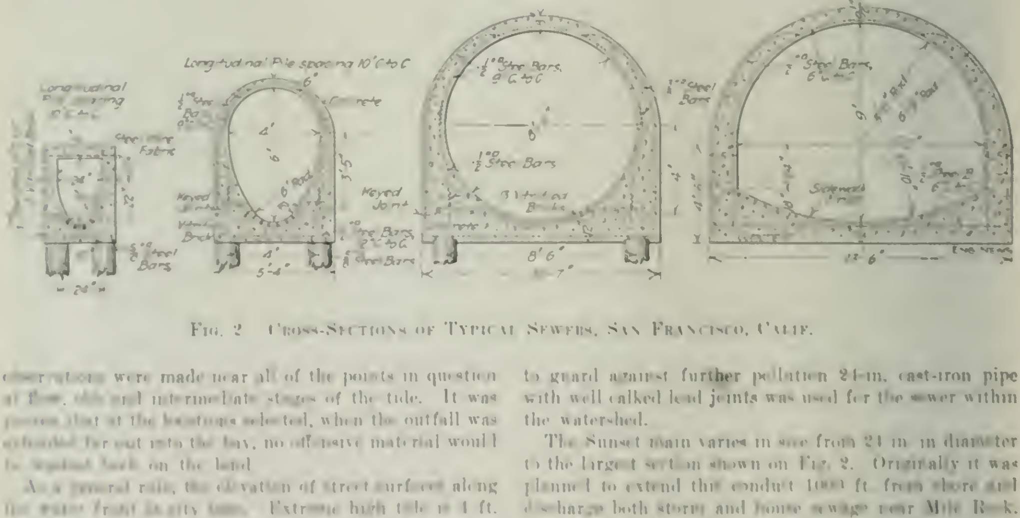


Fig. 2. Cross-Sections of Typical Sewers, San Francisco, Calif.

The Sunset main varies in size from 24 in. in diameter to the largest section shown on Fig. 2. Originally it was planned to extend this conduit 1000 ft. from shore and discharge both storm and house sewage near Mile Rock. From the results of float observations taken near Mile Rock, it is evident that at flow tide the currents would carry suspended matter in an eddy toward the shore and into the harbor, while at ebb tide all of the sewage would be carried out to sea. Only one float out of the entire number dropped at ebb tide was washed back on the beach, but even after this demonstration the precaution was taken of diverting house sewage from this locality.

Eastern Drainage Area

In the low level districts of the Eastern drainage area a separate system for house sewage was installed. Due to the necessity of providing drainage facilities for deep basements and a flow free from tidal influence, it was essential that sanitary sewers should be laid at considerable depths, the sewage directed by gravity to locations of minimum elevation and then raised by pumps into the

large high-level intercepting storm or combined sewers. Sanitary sewers were of salt-glazed, vitrified iron-stone pipe, and varied in dimensions from 8 to 20 in. In soft ground a pile foundation was provided and the pipe surrounded by reinforced concrete.

By far the greater portion of the city is provided with the combined system. Combined sewers constructed since 1906 are all of reinforced concrete, with a pile foundation wherever necessary to prevent settlement. The smallest size is a 2x3-ft. structure with egg-shaped invert and flat top, as shown in Fig. 2. The inverts of all concrete sewers were lined with vitrified brick in order to prevent scouring action.

In the eastern drainage area the largest combined sewer is the North Point main, which discharges into the bay opposite the foot of Sansome St. A district of nearly 12,000 acres, in which are the homes of over 80% of the population, is served by this sewer. Into it will also discharge three of the pumps by which the contents of the separate system are raised. When completed the North Point main will be approximately six miles in length. When flowing quarter full over four miles will be of sufficient sectional area to admit of inspectors traversing it in a steam launch.

Fig. 3. Equalizing Chamber in Triple-Compartment Storm Sewer

Besides the North Point main, the topography of the eastern drainage area rendered necessary two additional intercepting sewers. One drains the southern portion of the city and discharges at Hunter's Point; the second traverses the Panama Pacific Exposition grounds at the northern end of the city.

Both design and construction are now under the direction of M. M. O'Shaughnessy, City Engineer.

Wood Preservatives Used in 1913 by 93 wood-preserving plants, amounted to the following quantities: Over 108,000,000 gal. of creosote oil, 26,000,000 lb. dry zinc chloride, and nearly 4,000,000 gal. of other liquid preservatives. Over 153,000,000 cu.ft. of timber were treated by these plants, or about 23% more than in 1912. These are the figures given by the American Wood Preservers' Association in coöperation with the Forest Service of the Department of Agriculture, Washington, D. C. The report goes on to say that while in Great Britain and most of the European countries, practically all railway ties and telephone or telegraph poles receive preservative treatment, in the United States less than 30% of the 135,000,000 cross-ties annually consumed are treated, and that the proper treatment of an annual consumption of 4,000,000 poles may be said to have scarcely commenced.

Specification for a Non-Patented Bituminous-Macadam Pavement; Connecticut Highway Commission

The following specifications, drawn by Charles J. Bennett, State Highway Commissioner, of Connecticut, have resulted in a satisfactory bituminous macadam, or as some insist, a bituminous-concrete pavement. Being cold rolled, no elaborate apparatus is required for its construction and some of the work done under these specifications has been done by the state's own day-labor repair gangs:

QUALITY OF STONE

Unless otherwise specified, trap rock will be required. Only broken stone accepted by the Division Engineer will be allowed in the work. If trap rock is not required, the stone must be of a hard and compact texture and of a uniform grain. No disintegrated or rotten stone will be allowed. All stone shall be thoroughly clean before crushing and must be well screened, and free from injurious matter of every nature.

FIRST COURSE

SIZE—The broken stone for the first course shall be as nearly cubical as possible and shall consist of ¾-in. and ½-in. stone evenly mixed at the quarry or the run of the crushed up to ¾-in. stone without the dust.

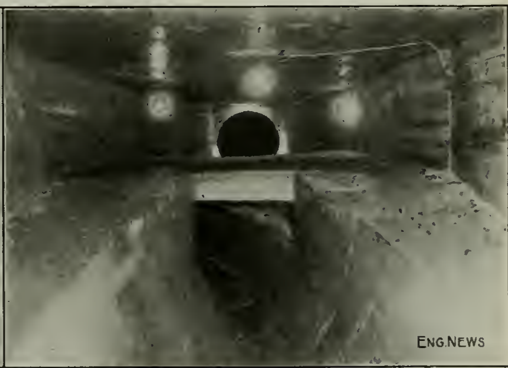

Fig. 4. Overflow Structure for Diverting Storm Water

BINDER—Texaco Macadam Binder or No. 161 Road Asphalt heated to a temperature of 300° F. shall be mixed with the stone using about 6½% of material by weight. The mixing may be done with a machine or by hand so long as properly proportioned and thoroughly mixed. This asphalt or binder shall be equal to sample submitted and shall be satisfactory in every respect to the State Highway Commissioner.

DEPTH—After the subgrade and roadbed have been made as specified a sufficient amount of this thoroughly incorporated aggregate shall be evenly spread thereon so that this course shall measure 2 in. in depth after rolling has been completed.

The stone shall be in a bone-dry condition, either naturally or having been dried out by the use of suitable heaters, if the weather is cold or moist and the stone damp. Under no circumstances, however, shall the stone be so hot as to cause the bitumen to fail to adhere to it in a coat of satisfactory thickness.

ROLLER—After the mixture has been spread for the first course, sufficient to roll down to 2 in. it shall be allowed to set for a period of at least two hours, and then a roller shall be run over the stone a sufficient number of times to form a firm and smooth surface of the proper cross-section. The wheels of the roller shall be oiled to prevent picking up the mixture in rolling. Should any unevenness or depressions appear during or after the rolling of this course, stone and bitumen shall be added to remove such uneveness or depressions.

SEAL COAT

ASPHALTIC BINDER—Immediately after the rolling of the first course a coating of Macadam binder shall be applied under pressure to the surface in the amount of ¾ gal. per sq.yd. so as to completely fill all interstices and voids with the hot asphalt. The temperature at which this asphalt is applied shall be about 1100° F. This macadam binder shall be equal to sample submitted and shall be satisfactory in every respect to the State Highway Commissioner.

SCREENINGS—Immediately after it has been spread, clean dry screenings, free from dust and sand shall be uniformly scattered over the surface and then rolled until the screenings are thoroughly embedded in the macadam binder of the seal coat.

ROLLING—The rolling shall be continued until the surface presents a smooth and finished appearance to the approval of the Division Engineer. Upon completion the road shall stand at least 12 hours before being opened for traffic.

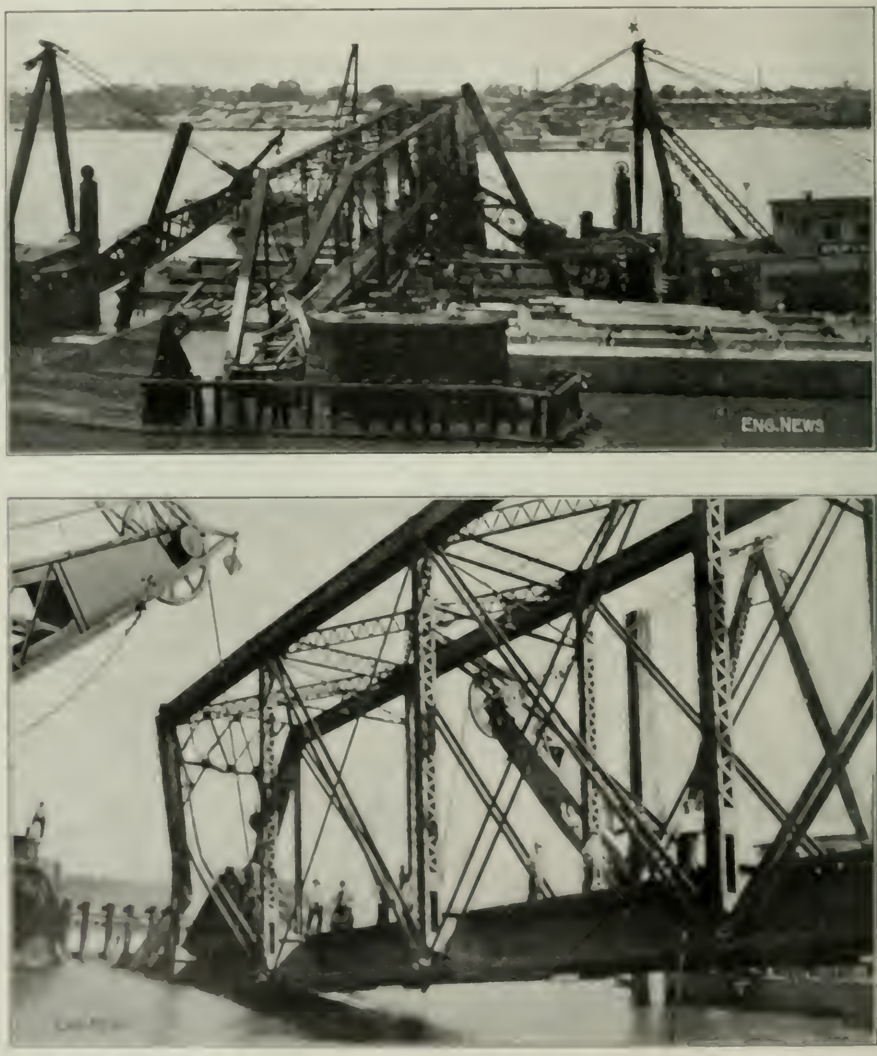
Raising and Repairing the Wrecked W. & L. E. R. R. Bridge over the Maumee River at Toledo, Ohio

By Edward U. Smith*

The wreck of one span of the Wheeling & Lake Erie R.R. bridge 2-A, over the Maumee River, at Toledo, Ohio, was noted in Engineering News, June 25, 1914. The span was 177 ft. instead of 150 ft. as stated.

It might be well to state that this particular span has

*Assistant Engineer in Charge of Bridges, Wheeling & Lake Erie R.R., Cleveland, Ohio.



Figs. 1-2. The Wrecked Span Being Raised by Two Great Lakes Dipper Dredges of 25-Tons Lifting Capacity Each

(Note the [illegible])

some back history, before describing the present accident and necessary repair work.

Prior History of the Bridge

Prior to the year 1896, this span was a wood-and-iron combination truss. It failed in 1895 while a heavy crane was crossing it, the crane and span both going into the river. A new steel span was built in 1896, designed for Cooper's E-35 loading and fabricated by the Toledo Bridge Works.

Pending the erection of the new steel span, piling was driven and frame bents set on top in order to carry traffic. On account of insufficient longitudinal bracing, these bents fell while a train was passing over, and several hopper cars were thrown into the river. The falsework was rebuilt with piling, omitting the frame bents.

In the year 1903, a boat failed to find the opening of the draw and hit this span, pushing it bodily into the river. On examination, the steel was found so badly damaged that it was necessary to build an entire new span. The new span, which was the one recently wrecked, was designed for Cooper's E-50 loading. It was fabricated by The American Bridge Co. and erected in 1904.

The Latest Accident

The wreck of June 11, 1914, was a remarkable accident, in that very little damage was done to the colliding barge and comparatively little to the bridge, considering the fact that it was torn loose from the pier at its fixed end and this end fell on to old piling which surrounds the pier and had been cut off below the water line. These old piles prevented the span from going to the bottom. It did settle about 14 ft. under the water. The other end, which was the expansion end, remained on the pier and was thrust against the next span with such force that it tore its anchor bolts loose and damaged the stone masonry to such an extent that the top of the pier will have to be rebuilt. The steel in this span was not damaged.

Raising the Wrecked Span Back to Place

With the aid of two Great Lakes Dredge and Dock Co.'s dipper dredges, having a hoisting capacity of 95 tons each, we experienced considerable difficulty in getting the span loose from among the piles. Once it was started, however, it was an easy matter to raise the span up far enough to get two water-ballasted scows under it. As the span was raised, the scows were pulled over as close as possible to the pier and timber cribbing was placed under the span as the dredges raised it. A final raising, of a foot or so, required to bring the span to the proper elevation, was accomplished by pumping water out of the scows.

After the span was up to grade, a line was run to the scow from the dredge, and the span was swung into its true alignment, by towing the scows downstream. The expansion end, which had remained on the pier, was fastened back to the second span beyond by two 1½-in. wire cables, with ship-wrenches inserted to take up the slack as the span was raised. This precaution was taken to prevent the span from moving forward off the pier while being raised.

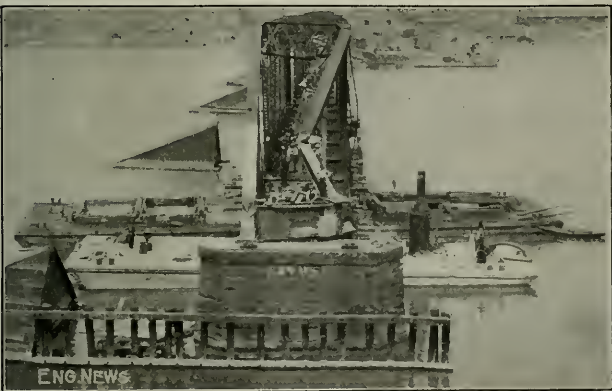


Fig. 3. Span Back in Place

Fig. 4. Supported on Pile Bents and Broken End-Post Removed

Restoring Traffic over the Wrecked Bridge

The damage to the span was found to be as follows, as will be seen in the pictures. The bow of the barge struck the end post and bottom chord, buckling them. This caused the portal, portal brackets and end floor-beam to buckle. The pin plates at the hip were sheared, allowing the end-post joint to open. The rest of the damage was caused by the impact with the piling.

The parts to be renewed were one end post, portal, portal brackets, two bottom chords for the first panel, one end floor-beam, one hanger, and two end stringers.

Restoring Traffic

To support the span and traffic while the new parts are being fabricated (by the American Bridge Co.), it was necessary to drive several pile bents. Using 55- and 60-ft. piles, single bents consisting of eight piles each, were driven, as nearly as possible under the first four panel-points of the wrecked span and the first two panel-points of the span next to the wrecked one. Single bents of eight piles each were driven on both sides of the damaged pier. One 24-in. 120-lb. Bethlehem girder I-beam

was placed under the posts, and one under each stringer of the second, third and fourth panels of the wrecked span, oak wedges being used to obtain a full bearing of the floor-beams on the I-beams. The end panel of this span, from which the damaged stringers were removed, is being carried on eight 9x18-in. yellow-pine stringers. The second and third floor-beams of the other span were simply blocked up on the pile bents.

In order to temporarily support the ends of the two spans over the damaged pier and to provide for the repair of the pier without further interruption of traffic, four 24-in. 83-lb. Bethlehem I-beams, 24 ft. long, were placed on the two eight-pile bents, immediately under each shoe. These 8 I-beams will be left in position and four 24-in. I-beams 8 ft. long, placed longitudinally, with a transverse grillage of 60-lb. rails, on the pier under each shoe to make up the depth of 52¾ in., the depth to which the top of the pier was removed. The pier will be capped with concrete and the ends of the 24-ft. I-beams will be cut off with an acetylene torch.

The wreck of this bridge occurred about 8:30 a.m., June 14, and the bridge was reopened to traffic on June 27. The new steel members have been fabricated and are now being placed in position without interrupting traffic.

The raising of this span was done under the personal supervision of W. L. Bolbock, Chief Engineer of the Wheeling & Lake Erie R.R.

⁂

A Large National Water-Works System for Cities and Towns in Southern Italy

By John C. Trautwine, Jr.*

To supply water for domestic consumption and public purposes to 4,000,000 people living in cities and towns in an arid section of 5000 sq.mi. in southeastern Italy, the Italian government, through a franchise contractor, is carrying water through the Appenines from western Italy by means of a long aqueduct and a network of cast-iron pipe, the whole of the conduits totaling about 1900 miles. Hydro-electric-power and water-power plants developed by the fall of water through the aqueduct, together with Diesel oil engines where aqueduct power is not available, will pump a large part of the water to cities and towns 300 to 700 ft. above the main conduits. The use of some 800 Venturi meters, a universal consumer's meter system, and the purchase of a large quantity of American pipe [illegible] in the interest of the works, which, with the reasons for their construction, are here briefly described.

Along the Eastern or Adriatic coast of southern Italy stretches a district, about 300 miles long, from northwest to southeast, and of a nearly uniform breadth of about 40 miles (see map). This district (once the Duchy of Apulia, or Puglia) comprises the three provinces of Foggia, Bari and Lecce. Its population is about 3,000,000.

The district is of a cavernous limestone formation, with very little ground cover, and is practically without fresh ground water. Wells yield only brackish water, and the few and small streams are generally dry in summer. The country is therefore dependent upon rain water, caught in cisterns. In 1908, from March to October, no rain fell, and the Government, during more than two months, was forced to send fresh water, for the relief of the 3,000,000 inhabitants, by railway and in war vessels.

In October, 1906, the Italian government began the construction of a gigantic water-supply system for the permanent relief of the people of Puglia. Eastward from Naples lies the watershed, an elevated district of dolomitic limestone, underlaid with clay, with an area of some 600 sq.mi., and with elevations of from 4000 to 6000 ft. above sea level. The rain falling upon this district finds outlet at only three points. One of these is the Serino source of the Naples water-supply; a second is being developed for the supply of Salerno, 30 miles east of Naples; and the third is the source of the River Sele, which is being used for the supply under consideration.

The Sele issues from the southeastern side of the district, in a spring, at Caposele, having an elevation, above sea, of about 700 ft., and flows into the Tyrrhenian Sea about 20 miles south of Salerno. The flow here is about 115,000,000 gal. per day, and is exceedingly constant; a little greater than normal in summer (when most needed), owing to melting snow. In the near neighborhood are three smaller springs, to be utilized eventually. They will increase the supply to about 150,000,000 gal.

Map Showing Location of the Puglia Water-Supply District, Italy

(Water naturally flowing westward into the Tyrrhenian Sea will be diverted from the headwaters of the River Sele, and carried eastward, by tunnel through the Appenines to the arid district of Puglia, on the Adriatic Sea.)

daily; for which quantity the works are designed. The water issues from this spring at a temperature of 48° F., and in order to maintain this low temperature, all pipes and conduits are required to be laid not less than 3 m. (say 10 ft.) below the surface; all reservoirs have a cover of the same depth; and any conduits, which, for any reason, cannot be given the prescribed 3-m. cover, are protected by air jackets about 8 in. wide.

The water of the entire district is of exceptional purity; so that no filtration, or other purifying process, is required. The Sele supply, moreover, is carefully protected against accidental or malicious defilement. The water furnished to Naples (notwithstanding its limestone source) is entirely soft, while the Sele supply is a trifle hard.

The natural basin, which forms the Sele spring, has been filled with loose broken stone, and roofed over, with the specified cover of 3 m., of reinforced concrete and earth.

*Consulting Engineer, [illegible], Philadelphia, Penn.

Here begins the aqueduct, which has here an ovoidal section of about 72 sq.ft., and a downgrade of 1 : 4000, which, with a few exceptions, is maintained throughout the entire length, between those points where water-power is utilized, as described below. The object of using the flat slope of 1 : 4000, is mainly to conserve the head for power purposes, at the expense of a larger cross-section than would have been sufficient with a steeper fall and higher velocities. The aqueduct will run nearly full. Except in the siphons, it is nowhere under pressure.

From the source, at Caposele, the aqueduct extends northeastwardly, passing to the south of Rionero and Venosa. West of Venosa branches off the line extending northward to S. Severo (the northern end of the system) and supplying Foggia, the northwesternmost of the three provinces constituting Puglia. Southeastwardly, the distribution extends to Cape S. Maria di Leuca, at the extreme end of the supply district.

The passage of the Appenines is effected by means of a series of tunnels, covered conduits, aqueduct bridges and inverted siphons.

Of the total length, 60 miles are in tunnel. Six of the tunnels have an aggregate length of 36 mi.; and, of these, one is 12 mi. long, or as long as the Simplon tunnel. The small section of these tunnels, and their down grade, of course added to the difficulty of their construction.

Some of the tunneling work has been of exceptional difficulty. In the first tunnel driven (over 9 mi. in length), the contractors encountered a plastic black clay, which swelled greatly when moistened. In the headings, close timbering, of 14-in. round logs, was bent inward, and the ends of the posts were driven bodily into the caps and sills, indicating a pressure far in excess of that due to the greatest height above the work, and suggesting an internal force due to the expansion of the material, caused by moisture. In this material, 1 to 3 ft. per day was the maximum rate of advance.

The last piece of tunneling, that at Croce del Monaco, has just been finished, after being greatly delayed by quicksands.

The siphons are of brazed steel pipes, in pairs, and in general with leaded bell-and-spigot joints, and incased in concrete.

The profile of the conduit consists of slopes, generally of 1 : 4000 (as already mentioned) separated by steeper slopes, from which water power is derived. The power is utilized, mostly by means of electrical transmission, in pumping from the conduit to the several towns, most of which are situated upon elevated sites, from 200 to 700 ft. above conduit level. In some cases turbines are directly connected with the pumps. Where water-power is not available, Diesel motors are used. All pumping stations are in duplicate, as a precaution against accident.

In the three provinces to be supplied, there are at present no villages, and even the farming population resides in the towns and cities; the farm workers walking (often many miles) to and from their work. This results from malaria, which infests the low lands, driving the inhabitants to the towns upon the hills; and from the fact that, formerly, the district was subject to incursions from warlike neighbors, who crossed the narrow seas which separate this part of Italy from its surroundings.

It is, however, provided, by law, that water is to be furnished, from the works described, to any who may wish to settle in its neighborhood, and it is believed that this, together with changed political conditions, and the general sanitation of the low lands, will conduce to the establishment of villages and small towns, and the creation of a rural population.

Construction

The work is being constructed by the Societá anonima Italiana Concessionaria dell' Acquedotto Pugliese-Genova (President, Senatore Giovanni Bombrini) under contract with the Italian government, the terms of which are fixed by a special law. Under this contract, the company receives 124,000,000 lire ($24,800,000), which will be largely exceeded by the cost of the work; but the company is given also the entire earnings of the works for a period of 90 years from their construction.

Not less than 400 Venturi meters are to be installed on the work, for the large-scale measurement of the water.

By the terms of its contract, the company is bound to supply each town with public fountains, in number proportional to the number of inhabitants. All other water, for both public and private use, is to be sold by meter, at sliding-scale prices, fixed by law.

With 3,000,000 population, and an eventual supply of 150,000,000 gal. per day, the per capita daily consumption will be 50 gal.

The cities of Puglia are as yet without sewerage systems. With the construction of sewers, the consumption of water may be expected to exceed the capacity of the works here described.

The company is required to furnish water only for domestic and public consumption (the latter only for public buildings, schools, etc., not for boiler use or for irrigation). The company has the privilege of furnishing water for other uses; but this is not contemplated for the near future. A project for irrigation, using another source, is now under study by the Italian government.

For each town, the company is required to construct a covered reservoir, holding not less than two days' supply.

The water is to be pumped to the elevated towns, from the aqueduct, through cast-iron pipes, with bell-and-spigot lead joints, requiring a total of about 120,000 tons of pipe. American industry is reaping some benefit from this work, the water company having contracted with R. D. Wood & Co., of Philadelphia, for the supply of about one-third of the cast-iron pipe required.

On an average, about 10,000 men have been employed upon this work for eight years.

The total length of conduits and piping will be about 3000 kilometers, or 1900 miles.

For the data here given I am indebted to Sig. Carlo di Chiusano, engineer to the contracting company, which he served chiefly in connection with its tunneling work. Sig. di Chiusano is now in America, looking after the execution of his company's pipe contracts.

A Pavement Problem in Reading, Penn., has grown out of an old court decision that the city authorities cannot assess abutting property owners for the cost of repaving macadamized streets with uptodate pavements. The streets being held to be already paved must be improved at the expense of the city as a whole. Of its 80 miles of paved streets Reading has about 60 miles surfaced with macadam, so the problem is a large one, and it has recently been studied by the Bureau of Municipal Research of New York City.

Tar-Formation Temperatures for American Coals

One of the troublesome points in the better utilization of miscellaneous American coals is the formation of tars; therefore, a recent investigation, which gives information on (1) the temperature limits of tar formation; (2) the temperatures of maximum evolution, and (3) the relative quantities evolved from various coals, is of wide interest and importance. This study was made by O. C. Berry while Assistant in Steam Engineering at the University of Wisconsin (and is being continued at Purdue University where he is Instructor in Mechanical Engineering). The following brief report is based on a detailed statement forming Bulletin No. 635, University of Wisconsin (Engineering Series, Vol. 7, No. 7).

When bituminous coal is fired in a boiler furnace, the volatile constituents are driven off at a comparatively low temperature and appear above the fuel bed. If the air supply, over grates, is insufficient or cold or if the volatile matter is chilled by cool parts of the boiler, carbon is deposited as soot or floats out as more or less dense smoke. The practical problem is to cause the volatile gases, carbon monoxide and tar vapors to mix with high-temperature air; a better knowledge of the temperatures at which tars distill and the rates at various temperatures then is of material aid in designing furnaces and grates and facilities for the best firing of the coal.

In coke manufacture, with the rise of byproduct processes, this same information is of service. Perhaps the most important field for its application, however, is in bituminous gas-producer work; tar vapors are particularly troublesome here, for if carried over to the gas engines, they clog up the pipes and valves. Complete separation of tar is difficult and more or less expensive. Attempts have been made to burn the tar and to "crack" it into permanent gases.

Tar formation temperatures have to be considered in such efforts—as for instance if air is introduced to unite with the tar at the last point where it is evolved in the fuel column, this point is determined by the temperature. In the scheme of drawing tar vapors off the top of the fuel column, introducing them under the grates and drawing tar-free gas off at the center height, such knowledge as mentioned is essential in securing good gas without excessive heat losses.

In the studies undertaken, furnace conditions were simulated but with such apparatus as afforded good control. It was desired (1) to heat the coal slowly and at a uniform rate; (2) to conduct the heat to the center of the coal body by good conductors; (3) to know the coal temperature at all times; (4) to sweep out the evolved gases as rapidly as formed; (5) to cool down the gases and continuously test for tar; (6) to prevent low-temperature deposition in the pipes and later high-temperature redistillation.

The furnace was a special resistance-coil design. The coal was held in a cartridge, $2\frac{1}{2}$ in. in diameter with small inlet and discharge pipes for blowing inert gas through, and with a thermometer well. To transmit the heat to the interior, perforated iron disks were packed with the coal $\frac{1}{4}$ in. apart. The sweeping-out gas was air with the oxygen burned out, furnished under pressure and at full furnace temperature. To test for tar a small stream of the gases direct from the cartridge was chilled and caused to impinge at high velocity on a paper ribbon. If there is any trace of tar it is deposited on the paper; Not quite all the tar evolved is secured owing to the rebound of the smallest and lightest of the tar particles; however, the deposit probably is nearly proportional to the entire tar content. To prevent redistillation, the pipe leading out of the cartridge was changed every 5 to 10 min., there being plenty of duplicates.

A study of the tests and results leads to several generalizations:

(1) Tars begin to distill from any grade of bituminous coal or lignite at some 300° C.

(2) Maximum evolution is between 375° and 475° C.

(3) Tars have been all evolved on reaching a temperature of 550° C. usually, though 600° is obtained for a few coals.

(4) Formation *temperatures* are not dependent on the geological age of a coal, amount of volatile matter, or carbon-hydrogen ratio in the class tested; tars may appear or disappear at approximately the above temperatures with any grade of American bituminous coals.

(5) No relation is evident between evolved tar and amount of volatile matter in the coal.

(6) A distinct relation is seen between *amounts* of tar evolved and the carbon-hydrogen ratio. Maximum amounts of thick tar came from coals with this ratio ranging from 13.5 to 18; knowing the carbon-hydrogen ratio of two coals and the tar evolution of one, the yield can be predicted with considerable accuracy for the other.

(7) The volatile matter of Western coals contains fixed gases and watery vapors of low calorific value—shown by small amounts of tar deposited but low-heating value of coal.

The specific data for 11 typical coals is given in the accompanying table.

TAR-FORMATION TEMPERATURES OF AMERICAN COALS

Coal	Geological age	Carbon-hydrogen ratio	Volatile matter per cent	Tar starts deg. C	Temp. max tar deposit deg. C	Tar ceases deg. C	Per cent of sample deposited on paper	Per cent of volatile matter deposited as tar	Heating value B.t.u. per lb.

A Mileage Charge to Owners of Motor Omnibuses to Pay for Road Repairs

The injury done to road surfaces by heavy motor trucks and motor omnibuses is beginning to be talked about by engineers in this country. It has hardly come as yet to the notice of the taxpayers, who pay the money to maintain the roads, a possible reason for which is that in a large proportion of the States the roads are not maintained in the proper sense of the word. and are allowed to be practically destroyed after construction before anything is done about it.

In England, however, the problem of making the owner of the motor vehicle pay for the damage he does to the roads he uses is already a question of practical politics. The London *Surveyor* states that on July 1, the Local Legislation Committee of Parliament considered the question of the contributions owners of motor busses should make to pay for road maintenance. The City of Sheffield desired authority to run motor omnibuses outside the city limits into adjacent counties. The county authorities opposed the granting of the privilege unless the City of Sheffield would pay enough for road maintenance to cover the resulting wear and tear. The Committee finally granted permission to operate four of the seven routes desired, on condition that the City of Sheffield would pay the counties ¾c. per car mile for all mileage traveled by its motor omnibuses within the county limits, this rate of payment to be subject to revision every three years.

The Chairman of the Committee also announced that a general act would probably be brought forward in Parliament, fixing a rule to apply to the whole country, as to the amount to be paid toward road maintenance by operators of heavy motor vehicles. It should be remembered in this connection that Great Britain already assesses a heavy license tax on all motor vehicles, graded according to the weight and power of the vehicle, the proceeds of which are devoted to road construction and maintenance under the National Road Board. The proposed special charge to users of heavy motor trucks and motor omnibuses is in addition, therefore, to the heavy tax already laid. The almost universal testimony of English road engineers is that this additional tax is a necessity to fairly repay the added cost of road maintenance due to these heavy high-speed vehicles.

Reducing Casualties on Construction Work

New York's new Employer's Liability Law, which went into effect on July 1, should bring about a reduction in the number of men injured on construction jobs. This result will not be realized at once. Employers must first appreciate the full measure of the added responsibility. On the first day of the new law, on a large building contract in New York City, one man was killed and three others injured by falling material. There have been other casualties on this same job from this same cause.

The dropping of objects constitutes one of the greatest hazards of building construction. This hazard increases with the area and distribution of the work; it is obvious that the dangers from this source are greater, for instance, at the Equitable Building, the largest office building in the world in point of floor area, than on some 20-story loft building or apartment house uptown, all other factors equal.

Other factors contributing toward the construction hazard are: the number of floors upon which work is in progress simultaneously; character of the work; speed of its prosecution; skill and intelligence of the workmen, and the vigilance and efficiency of the man in charge. The last two factors are especially important; mechanical safeguards can prevent but a small proportion of accidents where reckless methods are permitted. Coöperation between employer and employee, foremen and men, is absolutely necessary if the irreducible minimum of accidents is to be attained and maintained.

Careless handling of materials and defective plant equipment are going to cost employers a lot of money under the new law; and the sooner this is appreciated, the better for all concerned. Most failures of handling equipment can be traced directly to lax plant inspection

On a big construction contract where the responsibilities of the superintendent are too great and too pressing to permit him to personally acquaint himself with the condition of scaffolds and other falsework, derrick guys and cables, loads on tools, and methods of hoisting and piling material, it would be economy to place a competent man in charge of these details. Saving one man from death or serious injury might pay the salary of such a "Safety Man" for a year or for several years. When subforemen are held accountable for accidents, the result is usually divided responsibility. The duties of subforemen frequently overlap, when, of course, "nobody is to blame."

It must be frankly accepted that the most efficient method of prosecuting work is not always the safest. For instance, blasting can be carried on with comparative safety, but the work does not progress fast enough; it costs too much. In blasting for the foundation of a well known metropolitan skyscraper in a thickly populated district, a rock as big as a man's head was thrown two blocks, dropping into a large railway terminal. This was not "safety first."

There are conditions which demand speed even at the cost of inconvenience to the public; prohibitive financial loss to the contractor, etc. In such cases, the work should be pushed with the greatest speed commensurate with reasonable safety and with the maximum safety possible with that rate of prosecution.

Temporary coverings, floors, or "butterflies" of wood or corrugated metal should be built where practicable in new buildings to prevent tools, brick, tile and other small objects from falling through open space and striking men

working below. This sort of protection is required over sidewalks in most large cities. If the idea were followed up inside the buildings, fewer broken heads would be recorded. Such protection is especially desirable on wrecking operations.

The use of chains is diminishing and wire cables are being substituted where possible. Careful inspection often fails to discover worn links, but broken strands are readily detected. Mechanical safety devices in the form of safety grips on derrick or crane hooks, covered gears and boxed-in conveyors and hoists, etc., should be insisted upon.

The best way to stop abuses, nuisances, incompetent or slipshod methods, is to give them publicity. If all the accidents which occur in the building construction of a large city were recorded and published, safer methods would be used. From analysis of such statistics, causes of accidents would be revealed and met where possible with remedies. Contractors, who have to bear the expense of accidents occurring on construction work, would undoubtedly be glad to accept authoritative and practical recommendations for better practice.

Who Owns the Pennsylvania Railroad?

There is a widespread popular impression that the great railway and industrial corporations of the country, with their many millions of dollars of capital, are owned by a few wealthy individuals, and that legislative attacks upon them tending to destroy the value of their property will injure nobody except people who have already more money than is good for them. Nothing could be further from the truth.

We had occasion not long ago to carefully examine the list of stockholders of one of the great manufacturing combinations, a concern which is undoubtedly a "trust" in the popular acceptation of that term, and which has some $50,000,000 in common and preferred stock outstanding. It was little short of amazing to find how widely distributed was the stock of this company and what a large proportion of it was in small holdings, owned by persons scattered all over the United States. No single stockholder, as we recall, held over half a million dollars' worth of the stock and there were very few who held over $100,000. There was an enormous number of small stockholders with lots of five, ten, twenty or thirty shares.

We have not the accurate figures at hand as to the actual distribution of the stock in that trust, but we are able to give figures for the distribution in a far larger corporation, the Pennsylvania Railroad Company. According to figures just made public, the stock of the Pennsylvania R.R. Co. is now held by 90,844 people, of whom 44,[illegible] are women. The tendency toward a wider distribution of stock is shown by the fact that the number of stockholders increased over 8000 in the past year, and the average number of shares per stockholder dropped from 116 shares to 111 shares. The women stockholders hold, on the average, 64 shares apiece. As the Pennsylvania R.R. stock has a par value of $50, this means that the average Pennsylvania stockholder owns $5550 worth of stock, and the average woman stockholder holding Pennsylvania R.R. shares owns $3200 worth of stock, par value.

One occasionally hears the claim made that the Pennsylvania R.R. is owned by foreigners. While it is true that there are many stockholders of the Pennsylvania and other large investment corporations resident in foreign countries, the great bulk of the stock is held in the United States. According to a summary made on May 31, a third of the Pennsylvania R.R. stockholders, or 30,163, live in Pennsylvania; half as many more, or 15,350, in New York; 16,536 in New England, and 11,803 in foreign countries.

But in answering the question, who owns the Pennsylvania R.R., we cannot consider its 90,000 stockholders alone. Suppose the influences which are seeking to destroy all property values, and especially those held by corporations shall be finally successsful, so that a great corporation like the Pennsylvania R.R. will be compelled to steadily increase its expenses by paying higher wages to labor, etc., while at the same time its earnings steadily decrease until it can only pay its operating expenses, leaving nothing for dividends to stockholders or interest on its bonds.

It would not be merely the 90,000 stockholders of Pennsylvania R.R. stock scattered all over the country who would suffer loss as the result of such a campaign. The number of people who would lose by such a calamity would be numbered in the millions. They would include beside the 90,000 holders of Pennsylvania R.R. stock, the many thousands of holders of stock in other corporations which are affiliated with the Pennsylvania R.R. system and operated in connection with it.

But the stockholders after all are few in number compared with those who have an interest in the bonds issued by the company. The various bond issues of the Pennsylvania and its affiliated companies amounting to something like $300,000,000 are very largely held by savings banks and life-insurance companies, scattered all over the country. These bonds represent the accumulated savings of millions of men and women, working for wages, who have laboriously saved their earnings to provide for illness or old age. A campaign to annihilate property values could not be carried very far before a host of savings banks and life-insurance companies would have to suspend payments. Then would follow the appointment of receivers and in too many cases the dissipation of the remaining assets among a horde of hungry lawyers and political sharks.

The wide distribution of ownership in the Pennsylvania Railroad typifies the ownership of every other great railway and industrial corporation and is of interest also in connection with the current discussion respecting government ownership of railways.

The underlying idea in a large part of the agitation for government ownership is that the railways are now owned by a few individuals of enormous wealth, who are rapidly growing richer from the dividends and interest payments, whereas if the railways were taken over by the government, the government itself would hold all the stocks and bonds and would receive all the profits. But as the above discussion shows, the railways of the country are owned not by a few thousand wealthy individuals, but by millions of people who work for their living. The government could not and will not, until the forces of anarchy are triumphant, destroy the property belonging to all

these people and forcibly take it away from them. If we are to have government ownership of railways, it can only come about by the government buying the railways from the stock- and bondholders and paying for them in promises; or, in other words, government bonds. This would simply mean that the millions of people who now hold railway stocks and bonds would hold government bonds instead, and the government itself would be obliged to pay the interest on these bonds or go bankrupt, whether the railways earned profits enough to pay the interest or not.

If anyone believes that under government ownership the railways would be more efficiently and economically and honestly managed than they are now by their present officers under the supervision of State and Federal authorities—if anyone really believes this proposition, we suggest a careful study of our recent editorial wherein we reviewed what the government actually does in spending money on river and harbor improvements.

Until the United States government is administered with enough wisdom to stop spending many millions of dollars a year on works for inland navigation which are of no possible benefit to anybody, it would be the height of foolishness to place upon Congress the additional responsibility of directing the operation of the country's railways.

Laying Sewer Pipe with Water-Tight Joints

In our last week's issue we published a very interesting and carefully prepared article by J. M. Begg, Assistant City Engineer of Edmonton, Alberta, describing the methods which have been adopted in his practice in laying cement sewer-pipe joints so as to produce a water-tight line.

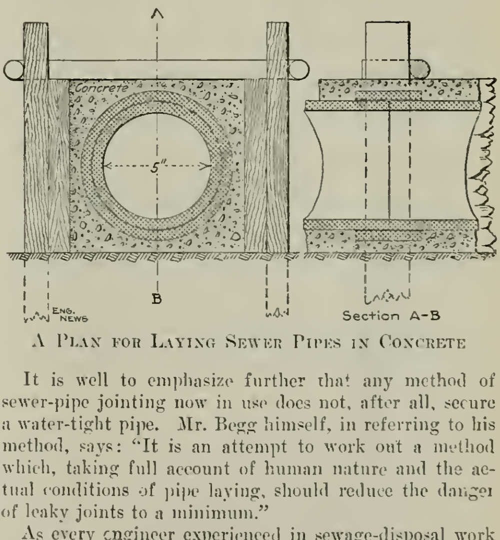
We wish to call special attention to Mr. Begg's paper in connection with the editorial suggestion on p. 1138 of our issue of May 21, in which we proposed to substitute in place of the present difficult and uncertain method of attempting to fill the joints of vitrified pipe with cement paste, the plan of surrounding the whole pipe with concrete. We discussed briefly the possibilities of this plan in the editorial referred to, but we wish to recur to it again and study its advantages farther, in connection with the statements made by Mr. Begg.

In laying sewer pipe by the suggested plan, when the bottom of the trench is finished to grade, two lines of boards would be set up on the bottom of the trench, the width between them being two or three inches greater than the diameter of the vitrified pipe to be laid, and held in position by stakes and clamps. Next, concrete would be deposited between these boards to a depth of two or three inches, and then the pipe would be laid and slightly bedded in the concrete. Next, concrete would be filled in on both sides and on top of the pipe, flush with the top of the boards, and slightly tamped or smoothed off to make the whole solid. When the concrete had set, the boards would be removed, ready for use on the next job.

The accompanying sketch shows sections of such a concrete-embedded pipe. In a sewer lateral of 5-in. outside diameter, embedded in a 7-in. square line of concrete, the cross-section of the concrete would be in the neighborhood of 30 sq.in., at which rate a cubic yard of concrete would be sufficient for nearly 135 lin.ft. of pipe. Assuming a cost of $5.50 for the concrete, which should be made, of course, with fine stone or gravel aggregate, the total cost would amount to only about 4c. per lin.ft. of pipe laid.

It should be worth very much more than this sum in any sewerage system to thoroughly secure the laterals throughout the system from the infiltration of ground water, to say nothing of eliminating the annoyance often caused by the penetration of tree roots into the sewers through defective joints. The cost of the concrete, however, would be largely offset by the saving of the expense of making and inspecting the sewer-pipe joints in the ordinary manner, as described in Mr. Begg's article.

As some of our readers may recall, R. H. Peck, of Palmerton, Penn., in ENGINEERING NEWS of June 4, declared that his trouble in getting water-tight joints in sewer work was so great that a rule had been established under which this work was done throughout the entire city by one experienced and reliable foreman. The difficulties presented when such an indispensable man takes a vacation, has a period of illness, or goes on a strike, are obvious.



A PLAN FOR LAYING SEWER PIPES IN CONCRETE

It is well to emphasize further that any method of sewer-pipe jointing now in use does not, after all, secure a water-tight pipe. Mr. Begg himself, in referring to his method, says: "It is an attempt to work out a method which, taking full account of human nature and the actual conditions of pipe laying, should reduce the danger of leaky joints to a minimum."

As every engineer experienced in sewage-disposal work is aware, tests of sewerage systems laid according to the specifications of the best engineers, and in the most thorough and conscientious manner, have shown that notwithstanding all the care taken, ground water to the amount of many thousands of gallons daily percolates into the pipes.

Nor is this the only difficulty experienced from the present methods of making sewer-pipe joints. As Mr. Begg points out, a very little carelessness on the part of the workmen will produce joints of an uneven thickness, pipes with an uneven grade, and projections of cement inside the pipe which, if they do not cause clogging, form little dams in which standing sewage collects, increasing the septic action, and the bad odors in the pipes.

All these difficulties should be obviated by the plan we have here suggested, of bedding the pipes in solid concrete. While the cement mortar in the concrete would

work into the joints to some extent, sufficiently to hold the pipes solidly and firmly in place, it would hardly creep so far as to enter the pipe itself. If it were found with very wet concrete that any trouble of this sort was experienced, it would be an easy matter to pull a bar through the pipe before the cement set, as is often done to avoid trouble with cement joints laid in the ordinary way.

As we pointed out in our recent editorial, the possible usefulness of the suggestion we have made is not limited to the sewer laterals only 4 to 6 in. in diameter on private property. It would be equally advantageous to apply the same system to the laying of street sewers up to a diameter of at least 12 ins. While the amount of concrete required would be considerably larger, it would still be a very small percentage of the total cost involved; and besides the water-tightness secured thereby, the protection of the sewer from injury by workmen engaged in other street excavations is an advantage of no small importance.

Still further, if engineers in considerable numbers were to adopt this method of laying sewer pipe in sizes up to say 12 ins. in diameter, it would doubtless lead to a reduction in the cost of the pipe, which would at least partially offset the cost of the concrete in which it was laid. It is probable that straight lengths of sewer pipe without the bell and with plain collars to cover the joints in place of the bell, could be manufactured at a materially lower cost than the present form of pipe. Such straight pipes could be piled and transported with much less loss by breakage. It is the projecting bells in a pile of sewer pipes that generally suffer when breakage occurs.

Such straight lengths of pipe, laid with collars, would eliminate any possible question as to the water-tightness of the construction described. It will be admitted, doubtless, that any water which enters a line of glazed sewer pipe must enter through the joints. In order to enter the joints of a concrete-embedded pipe it must percolate through a considerable thickness of concrete, and with closely fitting collars instead of bells for the joints, the cross-sections of concrete through which percolation could occur would be so exceedingly small as to eliminate almost the last possibility of leakage.

We trust that some of our readers engaged in this field of work will try out the system above suggested and report results.

Letters to the Editor

Narrow Tires as Road Destroyers.

Sir—Some years ago you said that I exaggerated greatly the effect of bad wheels—narrow tires—on macadam roads. Did you notice that a year or two ago the Massachusetts Highway Commission confirmed me? At least I understand that the Commission has reported that it is heavy loads on narrow tires that cause damage, not motor vehicles.

Of course the Commission should have known what a road—what a wheel—is without being shown, but after all their moral error is in not seeing that *light* loads on narrow tires are cutting out their general problem for them.

I believe that if you had properly reported this discovery, Governor Glynn of New York State might not have fallen into (or might have fallen out of) the error of saying recently that, in Massachusetts, experiments showed that the automobile is the worst vehicle for wear on roads!

I do not think so much of your claims to be the [illegible]

We are trying to build good roads for bad wheels! How [illegible] Missouri experiment station trials. Collecting and averaging the trials in Bulletin No. 39, I found these remarkable results:

[illegible]

1½-in. tires on earth roads, average lb. pull per ton, 86 = 141%.

1½-in. tires on macadam roads, average lb. pull per ton, 71 = 116%.

6-in. tires on macadam roads, average lb. pull per ton, 55 = 90%.

Just think of our fool investment in rolling stock which constantly produces in roads and vehicles, and requires from horses, 41% excess pull per ton on earth roads and 30% extra on macadam and gravel roads. I can't see why you keep mum so absolutely as to what great things good wheels would do. If a hint to the wise is sufficient, this should be ample for you, but, alas, there is none wise as to roads!

The Proportional-Flow Weir Devised in 1896

Sir—Herewith I hand you a copy of Vol. 1, No. 1, of the *Transactions of the Nebraska Engineering Society*, published in 1897. On p. 74 you will find an article by me entitled "A New Form of Weir Notch." I am unable to see that the article entitled "A Proportional-Flow Weir," appearing on p. 1300 of ENGINEERING NEWS of June 25, 1914, goes beyond this.

The same problem was worked out independently at a later date by Prof. Clarence T. Johnston, of the University of Michigan, who at that time was assistant chief of the Irrigation Investigations of the United States Department of Agriculture, and at a still later date by Prof.

Joseph Le Conte, of the University of California. Professor Le Conte has further pointed out, in correspondence addressed to me, that by expanding in series the form to be integrated in deriving an expression for the discharge, it is seen that a weir notch may easily be devised to give a discharge proportional to any desired power of the head on the crest.

In addition to the uses indicated in my article, the weir has been employed to a limited extent to measure the flow in small farm laterals used for irrigation, the weir being set in a diaphragm which has a sharp edge on the bottom and sides, so that it may be set down at any place in such a lateral where the banks are high enough to prevent overflow from the water backing up above the weir. I believe some use has been made of it in the laboratories of the University of Illinois.

O. V. P. Stout.

University of Nebraska, Lincoln, Neb.,
June 28, 1914.

[The weir form of Prof. Stout was exactly the same as that shown by Prof. Rettger, being of such outline that the breadth of the notch at any point is inversely proportional to the square root of the height above the crest. The formula is demonstrated, viz., discharge is directly proportional to depth of flow over crest. Prof. Rettger's method of correcting the weir form for varying coefficient of discharge is an addition to the subject, apparently.

Prof. Stout pointed out the disadvantages of this weir: its limited capacity, and the greater loss of head than in other forms of weir. At capacities over about 2 cu.ft. per sec., he says, the weir becomes ungainly.

The weir was used to measure water pumped by windmills at the farm of the Nebraska Agricultural Experiment Station. Prof. Stout believed it to be applicable to a variety of water measurements in agricultural, industrial and domestic use.

The value of the proportional-flow weir—or weir-notch—has not been recognized sufficiently, it would seem. That the Stout notch found use only locally and then was forgotten is surprising. However, similar notches are used in chemical-feeding devices in water purification.—Editor.]

NOTES AND QUERIES

What Is a Bituminous Macadam Pavement?—George C. Warren, President of Warren Brothers Co., Boston, Mass., objects to calling some of the roads illustrated on pages 1342-1344 of our issue of June 18, bituminous macadam. He recognizes the illustrations as those of roads constructed by the "Warrenite" process, which he says is a bituminous concrete, quoting as authority the definitions recommended by the committee on bituminous paving nomenclature of the American Society of Municipal Improvements, and adopted by the society in 1911. That was three years ago, but to establish a change in language is extremely difficult, and we believe it is still common to call any road in which broken-stone aggregate is held together by a bituminous binder a bituminous macadam, irrespective of whether the road was constructed by the penetration process or by mixing, or whether it has or has not the "inherent stability" claimed for the "Warrenite" construction.

Design of the Davis Reservoir Outlet, Turlock Irrigation District

In connection with the account, last week, of the failure of the Davis Reservoir embankment in California, a field sketch was shown of the outlet—one side of which gave way. We are able this week to present in more complete form the design of this part of the works.

In Testing for Gas in Coal Mines, small animals may be used repeatedly without danger of their being less susceptible to carbon-monoxide poisoning after many exposures than after the first, if they are allowed to recover between exposures. An investigation of the Bureau of Mines, the results of which were published in Technical Paper 62, showed that canaries are less resistant to CO poisoning than mice, chickens, rabbits, guinea pigs, or dogs. The bulletin recommends that canaries be used wherever possible, and that at least three of them be carried by an exploration party. Men may display distress in the presence of proportions of carbon monoxide as small as 0.10%; whereas small animals, in the same atmosphere, may show no signs of being affected.

The Largest Elevated Steel Tank

By R. W. Becker*

The surge tank just completed at Altmar, N. Y., for the hydro-electric power plant of the Salmon River Power Co., is the largest known structure of its kind, having a total capacity of 1,500,000 gal. This is a hemispherical-bottom tank with a cylindrical portion, 50 ft. in diameter and 80 ft. high. It is supported by ten steel columns raising the top of the tank 185 ft. above the top of the foundation. These columns are braced by two sets of struts forming the equal tower panels each about 31 ft. long.

This surge tank, located on the top of a hill, is connected to the lower end of a pipe line conveying water from the dam to the penstocks. The pipe line is 9500 ft. long, being 11 ft. in diameter at the dam and terminating in a 12-ft. distributer pipe. Four penstocks 8 ft. in diameter lead from the distributer pipe to the power plant below. The entire plant is designed to generate 40,000 hp.

A 12-ft. tee in the distributor pipe connects to the 12-ft. riser pipe of the surge tank. This riser terminates in an expansion joint below the tank so that about four feet of the pipe are carried directly by the tank bottom. To this latter piece of pipe the inner 10-ft. riser pipe is connected by twelve vertical I-beams. This is 100 ft. long and is carried entirely by the tank bottom. The only point of bracing is at the top where the riser flares out to a diameter of 15 ft. The lower end has a diameter of 10 ft. 8 in., thus affording an annular opening 8 in. wide between the two riser pipes.

This feature of the construction makes the surge tank a "differential regulator" and the twelve spaces into which the annular opening is divided by the I-beam connections are called "differential ports." The principal function of these ports is to retard the flow from the main tank to the turbines when the load on the plant is suddenly increased, so as not to apply the full accelerating head to the pipe suddenly; another function being to check the rise in pressure more gradually than would be the case without such ports, when load is thrown off. This is the invention of Raymond D. Johnson[1] of Niagara Falls, N. Y. On account of the economy of the "differential regulator," its extensive use in hydro-electric power installations is expected in the future.

The water, surging up and down, causes a difference in the water levels of the tank and the riser pipe which at times is very considerable. When the water rushes out, the difference in the water levels causes an external pressure on the inner riser pipe tending to collapse it. The [illegible] plate of this riser was reinforced by an angle [illegible] every 3 ft. 6 in., riveted on the inside so as safely to withstand an external head of 65 ft. of water.

The sudden exit of water also causes a partial vacuum which affects the tank and protective ceiling. This external pressure was assumed not to exceed 100 lb. per sq.ft. Vacuum holes in the ceiling were designed to minimize the external pressure. The assumed loading necessitated the reinforcement of seven of the 8-ft. tank rings with a pair of $5 \times 3\frac{1}{2} \times \frac{7}{16}$-in. angles on each. All this is shown in Fig. 3.

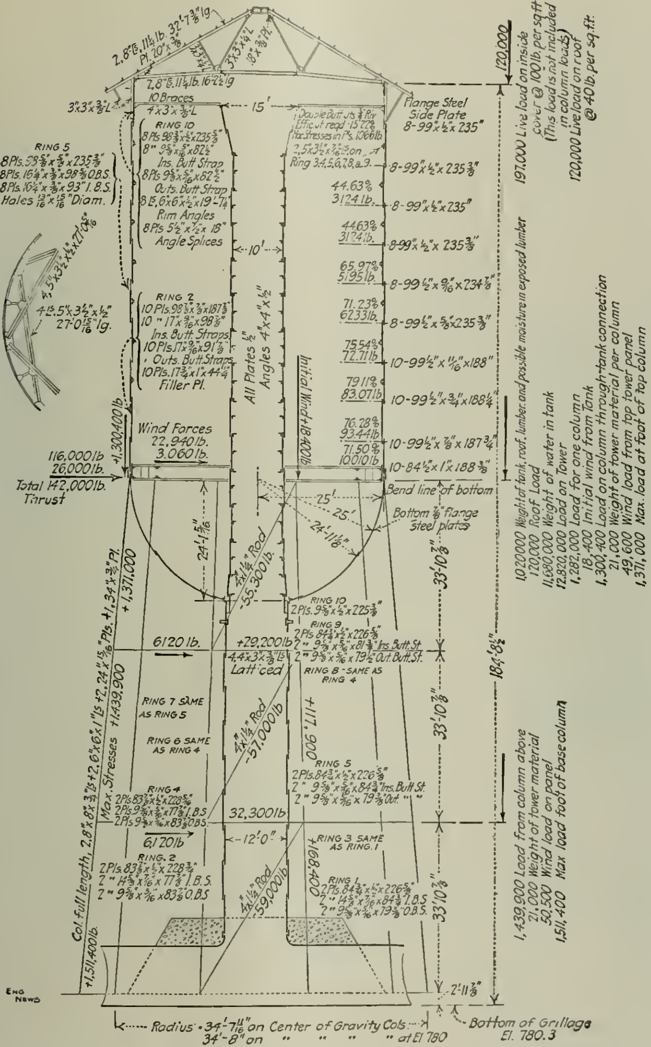
The entire tank and riser are inclosed by double cypress sheathing attached to 3x12-in. pine studding so as to form a 12-in. air space. The lower sheathing incloses a stairway to the bottom of the tank from which level an inclosed steel ladder leads to the top and inside of the tank. Hot air will be circulated within the inclosure from heaters at the foot of the lower riser pipe when temperature conditions require it. The entire tank inclosure is carried by the steel work.

Fig. 1. The 1,500,000-Gal. Surge Tank at Altmar, N. Y., Nearing Completion

The wood ceiling is carried on the lower chords of the ten main and ten half-roof trusses. The trusses are also designed to carry a live load of 40 lb. per sq.ft. and a suitable wind load. An asbestos covering on double sheathing and wood purlins is used. The roof projects 6 ft. over the tank, the trusses being stiffened by 20 brackets. These brackets extend down the full height of the top ring, thus reinforcing the latter under the heavy roof loads. The top of the tank is reinforced by a 6x6x

*[illegible]

[1]The "differential regulator" is fully explained in a paper [illegible]. It is entitled "The Surge Tank in Water Power Plants."



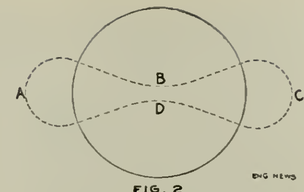


FIG. 2

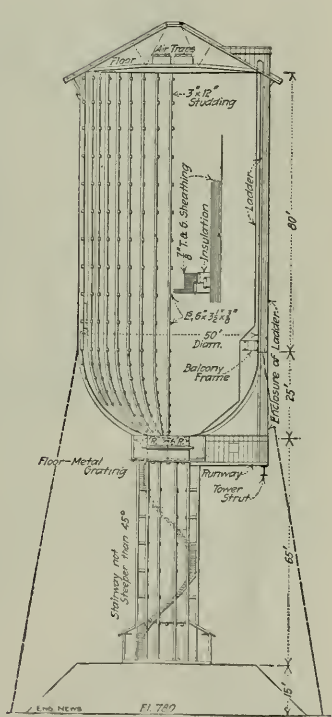

FIG. 3. DIAGRAMMATIC ELEVATION OF ALTMAR SURGE TANK, WITH STRESSES, ETC.

FIG. 4. PROTECTIVE COVERING FOR STEEL TANK AND UPTAKE

½-in. angle to take the horizontal thrust of the roof trusses, and to hold the tank in a circular form. The tank is also stiffened by the ten braces holding the inner riser pipe in alignment. No plates less than ½ in. thick were used in the tank and riser pipes. All plates were of openhearth flange steel and all steel was rigidly inspected at the mill. The specifications for the shop fabrication were in accordance with the best practice in bridge construction.

On account of the limited space of this article a discussion of all the original features of this design is not given, a few are mentioned briefly. The method of determining the stresses involved due to the external forces assumed on the main tank and riser pipes is entirely original. External hydrostatic or similar forces on a perfect cylindrical form can produce only a pure compressive stress in the shell just as the internal hydrostatic forces can produce only pure tension. The only difference between the two loadings is that while the internal one tends to correct any deviation of the cylinder from a perfect circular section, the external one tends to increase the deformation and consequently tends to increase the stresses.

From observation, we notice that when a pipe fails by collapsing due to an internal negative pressure, two diametrically opposite sides try to meet while the other

Fig. 5. Altmar Tank in Second Stage of Erection

two sides increase the distance between them as far as possible. The usual tendency is for not more than two sides of a pipe to move inward. There are, therefore, four points of metal, *A*, *B*, *C*, *D* (Fig. 4), which when considered very small, show no relative movement with the adjacent metal. All molecules of metal between these points, however, changed their positions with reference to adjacent molecules in their movement from the original cylindrical portion of the tank sufficient to show no perfect circular section. It, therefore, follows that the collapse is due entirely to the inability of the metal between the points noted, safely to carry the imposed stresses. As before stated, the stresses are purely compressive. The metal between *A* and *B* must, therefore, have failed as a column whose length is the distance from *A* to *B* measured on the center line of the plate. The distances between the four points are approximately equal, their inequality being due only to variations in the rigidity of the plate. Therefore, to design a cylindrical shell for external hydrostatic pressure, we need only consider one-fourth of the circumference of the plate as the column length. The stress in this column is computed the same as for the internal pressure, and is equal to the head times the radius in inches. When the slenderness ratio is large, Euler's formula for long columns should be used.

If the section of plate required for the computed stress is very thick, it is preferable to use a lighter plate with some reinforcement at regular intervals. The column then consists of a width of plate equal to the distance between reinforcements, with the reinforcing section at the center of the plate. The reinforcement used on the tank and standpipe can be checked by this method.

The principal stresses in the tank bottom are due to (1) the head of the water in the tank; (2) the weight of the 10-ft. riser pipe; and (3) the 12-ft. opening for the riser connection. The thickness of plate used is sufficient to take all these stresses without following the custom of concentrating metal around the opening. The local concentration of metal in any stressed spherical shell is an objectionable feature. The stresses due to the opening are a maximum at the bottom and gradually diminish until they vanish at the top of the bowl.

Only one thickness of plate is used which would indicate an unnecessary thickness of plate at the top if the method of support is not considered. As the tank is supported at ten individual points, a concentration of stress results at these points, which fact is ignored by most designers. The magnitude of the increased stresses at the supports varies in different designs with the actual

Fig. 6. Foundations for Altmar Surge Tank

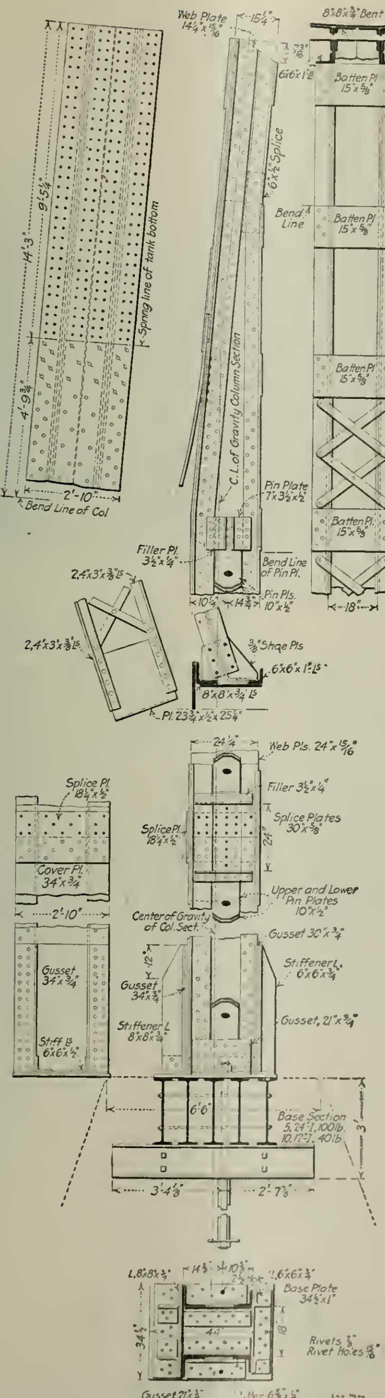

FIG. 7. COLUMN FOR STEEL TOWER

elongation of the material in the span between posts. To obtain a uniform stress in the bowl between supports, it would be necessary to use a thickness of steel in the ceptible elongation under full loads.

There must also be a circular reinforcement in a horizontal plane at the top of the bowl sufficient to permit of no inward deflection between these supports. As such requirements are not practical, it is advisable to ascertain the additional stresses caused due to the elongation of the tank plates used. The bottom plates should be thick enough to take these additional stresses and come within the allowable unit stresses, and the riveting on the horizontal seam should correspond. On the usual sizes of

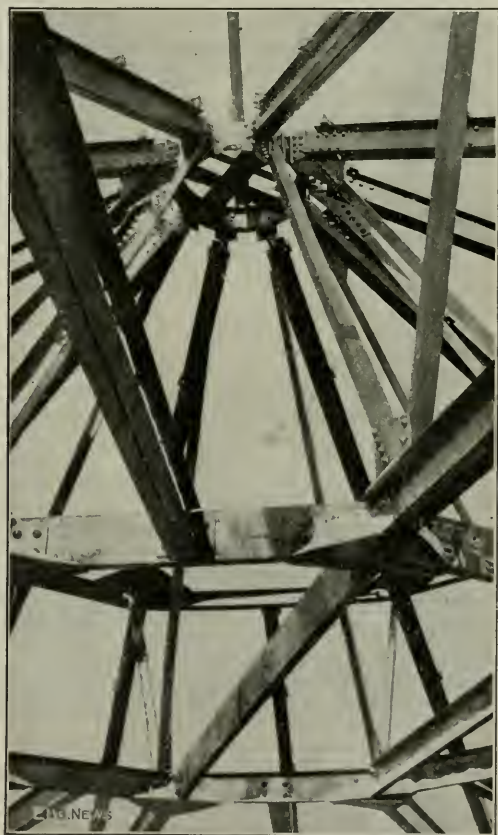

FIG. 8. ROOF FRAMEWORK FROM INTERIOR

tanks, these stresses are important only when large spans are used between supports. The bottom as here designed reduces bending stresses in the lower part of the tank cylinder to a minimum. Most designers are content to have the factor of safety take care of these stresses in the lower rings. Tank bottoms which are comparatively flat spherical segments or shallow elliptical bottoms depend almost entirely on the cylindrical shell to carry the transmitted shears to the posts.

The horizontal thrust of the columns at the top is carried by an interior truss work which also stiffens the

lows between posts. Further stiffening is accomplished by the two horizontal belt straps. On account of the importance of this structure a factor of safety of not less than five was used throughout.

Each of the ten columns is anchored by means of two 2½-in. bolts. They rest on a double tier of steel-grillage beams which are set at an angle to take the load of the columns correctly. The beams rest on concrete piers which are connected at the bottom by a heavily reinforced-concrete slab connecting them in a circle.

The tower, first ring, bowl and part of riser pipe were erected by means of a special steel derrick consisting of a 110-ft. mast, a 125-ft. boom and having a 20-ft. bullwheel. The upper 10 ft. of riser pipe was then completed and two 40-ft. swinging booms attached near its top from which the tank and roof trusses were erected (Fig. 5). All rivets were driven by pneumatic hammers and the work was closely inspected in the field as well as in the shop. The few leaks which were found after testing were quickly stopped. The tank was tested during very cold weather in order to rush its completion. To keep ice from forming on the water, a 2-in. steam pipe was run over the top of the tank and by the use of three swivel joints, was supported on floats which held the steam nozzle a few inches below the water surface.

This structure was designed by the writer for the Kennicott Co., of Chicago Heights, Ill., who fabricated and erected it. The work was directly in charge of the general superintendent, Chas. F. O'Connell. The Eric Construction Co. are the general contractors for the hydro-electric power plant. R. D. Johnson, their hydraulic engineer, made the complete specifications. The work was passed upon in detail by V. G. Converse, Chief Engineer of the Salmon River Power Co.

A Real Fireproof Building

The June 25 fire at Salem, Mass., produced one very striking example of the fire-resisting qualities of a well built concrete building with the openings thoroughly protected by wire-glass and by fusible-link shutters. The large plant of the Naumkeag Steam Cotton Co. was located at the extreme eastern end of the burned area and was almost the last place the fire reached. Like everything else in the path of the fire, all of the buildings were destroyed, with the exception of a reinforced-concrete storehouse and an old gasometer, which had also been used as a cotton storehouse.

The reinforced-concrete warehouse, built about eight or nine years ago, is 60x100 ft. in plan and four stories high. It is of reinforced concrete throughout, with straight column-and-girder construction, having plain slabs reinforced with expanded metal spanning the girders and with girders strung between the columns. The roof was covered with tar and gravel. The outside walls are provided with small windows, glazed with wire-glass set in iron frames and protected on the inside by hinged, metal-covered shutters, ordinarily held open by chains with fusible links at the outer ends. The building was designed and built by the Eastern Expanded Metal Co.

The warehouse is bounded on two sides by streets, while a third side faces a wide alley, so that only one side, where buildings stood within 6 ft., was subjected to the fiercest flames. The difference in the intensity of the heat to which opposite sides of the storehouse was exposed, is shown by the fact that, while on one side the rain-water conductors and the zinc flashing at the edge of the roof were melted down, on the opposite side, which faces a 40-ft. street, a wooden beam, bolted to the wall of the building to carry insulators for electric wires, was not even charred. The buildings on the opposite side of the street were, however, burned, and the heat on that side, as well as on the others, was sufficient to melt the fusible links holding the window shutters so that all of them were closed automatically.

That the temperature inside the building did not become excessively high is shown by the fact that the fusible heads of the sprinkler system, set to melt at 160° F., did not open in a single instance. Neither was the white paint, with which the interior walls are covered, blistered, and practically no damage was done to the $30,000 worth of finished goods which the storehouse contained.

The outside walls of the building appear to be absolutely unhurt. Most of the wire-glass in the windows is badly cracked, but no other damage is apparent and one would not guess that the structure had been in the midst of a conflagration except for the surroundings. The building cost about $25,000 to build, including the elevator and electric work. This is about 12c. a cu.ft. of volume above the street level.

The Manufacturers' Mutual Fire Insurance Co., of Providence, R. I., of which John R. Freeman, M. Am. Soc. C. E., is president, which had to pay about $800,000 for the losses in the Naumkeag company, has issued statement of the conditions around that plant. From that report we give below some extracts.

The loss is by far the greatest single loss that has ever occurred in the seventy-nine years' experience of the Factory Mutual System. The loss next in importance to this was that of the Warren Manufacturing Co. about nineteen years ago, in which the mutuals lost less than one-fourth part of the present amount. The present loss involves one of the largest payments (if not the largest) ever made to a single corporation for a fire loss. It is of interest to note that although more than 250 acres closely covered with dwellings, etc., was burned over, about one-fourth of the whole value burned was in this one factory yard.

The loss was in every way a legitimate one, and the exposure could not have been fairly called bad enough to forbid taking the risk. The risk bordered Salem Harbor and was divided into six principal buildings separated by reasonably broad open spaces. The flames that swept were driven toward these from a burning area extending over a mile back and a third of a mile in width and across these mills along their exposed front of about a quarter of a mile in length with a heat that no ordinary construction could withstand. Moreover, this was almost at the end of the conflagration, the city water pressure had been rendered practically useless by fire drafts and broken pipes, and no public fire apparatus and no public firemen put in an appearance at the mill or rendered the slightest assistance. A few men of the factory organization worked valiantly and worked to the limit, the mill's own big fire pumps fed from the harbor, and when these men were finally driven away they left the pumps running at full speed and a full head of steam on the boilers. They had to escape with two of the factory mutual engineers who were on the ground helping the men, by a boat, the mill being then all on fire, entirely surrounded by flames on the land side. Along the front after the fire had reached the mill it was impossible to hold hose lines in the smoke and heat, and more sprinklers were opened by heat than the pumps could supply. A radical substitution of new machinery for old throughout most departments had just been completed and last year they had [illegible] their fire protection appliances at an expense of about ten thousand dollars.

No more complete burning of everything combustible has ever been witnessed, with the exception of two storehouses—one a low circular structure, without windows (formerly a gasometer) used for the storage of cotton, the other a new four story concrete storehouse for finished goods, which had

FIG. 1. A REINFORCED-CONCRETE SURVIVOR OF THE SALEM FIRE. STOREHOUSE OF THE NAUMKEAG STEAM COTTON CO.

FIGS. 2-3. CONDITION OF THE REMAINDER OF THE NAUMKEAG PLANT AFTER THE FIRE

small wire-glass windows in iron frames, reinforced on the inside by tin-clad shutters dropped by automatic fusible links. This building, although surrounded on all sides by a sea of flames, came through the fire practically uninjured, except for the cracking and melting of the wire-glass in a few of the windows and a little smoke damage.

This concrete storehouse is a most instructive object lesson as to the feasibility of building storehouses at moderate cost that will withstand the fiercest conflagrations, and is well worth a visit by anyone about to build a storehouse.

⁂

The Cost of City Government in 195 American cities having 30,000 population and over is reviewed by the Census Bureau in a bulletin shortly to be issued. The statistics give the total cost of carrying on the general government, police and fire departments and all other protections to person and property, conservation of health, sanitation and street cleaning, care of highways, charities, hospitals and correction and conduct of education and recreation. Expenses in connection with public service enterprises, such as municipal waterworks, etc., are not included. The average annual per capita payment for the 125 cities is $17.34. The expense is higher, however, in the larger cities. In the cities of group 1, having a population in excess of 500,000, the average per capita cost is $21.24. In this group Boston has the largest ratio of expense, the amount being $28.06, and Baltimore has the lowest, the amount there being $15.14. In the group of cities having 300,000 to 500,000 population the average per capita expense is $20. In this group Washington is the most expensive city, the per capita cost being $25.43, and New Orleans the lowest, with $12.79. In the cities with 100,000 to 300,000 population the average per capita cost drops to $14.22, in the cities with a population of 50,000 to 100,000 the cost is $12.06 per capita, and in the cities of 30,000 to 50,000 population the cost is $11.69 per capita. As would be expected, however, there is great variation in the cost of city government in the different cities. In Mt. Vernon, N. Y., for example, the per capita cost is $27.53, and in Charlotte, N. C., it is only $6.44. The statistics also show a large and steady increase in the payment per capita on account of police, fire and education. The per capita expenses for education increased from $3.61 in 1902 to $5.02 in 1912.

The Newly Created State Department of Health of Massachusetts

The Massachusetts State Board of Health was legislated out of office on July 7. In its place, there was created a State Department of Health consisting of a single commissioner as executive officer and a council of health. The council will be made up of the commissioner and six other members. It will make rules and regulations, and perform other functions, not clearly defined, but will have no administrative or executive functions. The act substantially in full is as follows:

AN ACT

To create a State Department of Health and to amend the Public Health Laws.

There is hereby created a state department of health which shall exercise all the powers and perform the duties now conferred and imposed by law upon the state board of health. The state department of health shall consist of a commissioner of health and a public health council. There shall also be directors of divisions, district health officers and other employees as hereinafter provided.

The commissioner of health shall be appointed by the governor, with the advice and consent of the council, and he shall be a physician skilled in sanitary science and experienced in public health administration. The term of office of the commissioner of health shall be five years. He shall receive an annual salary of $7500, and shall devote his entire time to his official duties. The commissioner of health shall be the administrative head of the state department of health. His powers and duties shall be to administer the laws relative to health and sanitation and the regulations of the department, to prepare rules and regulations for the consideration of the public health council, to appoint and remove, with the approval of the public health council, directors of divisions, district health officers, inspectors and other necessary employees and fix their compensation, subject to the approval of the governor and council, within the limitations of appropriations therefor. Directors of divisions and district health officers shall be exempt from civil service regulations. The commissioner of health shall submit annually to the public health council a report containing recommendations in regard to health legislation, and shall perform all executive duties now required by law of the state board of health and other duties incident to his position as chief executive officer. He may direct any executive officer or employee of the state department of health to assist in the study, suppression or prevention of disease in any part of the commonwealth.

The public health council shall consist of the commissioner of health and six members hereinafter called the appointive members, at least three of whom shall be physicians, all to be appointed by the governor, with the advice and consent of the council. [illegible] The terms of office of the said members [illegible] shall be three years. Vacancies shall be filled by appointment of the governor, with the advice and consent of the council for the unexpired term. The public health council shall meet at least once in each month and at such other times as they shall determine by their rules, or upon the request of any four members, or upon request of the commissioner of health. The appointive members shall receive [illegible] a day while in conference and their necessary traveling expenses while in the performance of their official duties. It shall be the duty of the public health council to make and promulgate rules and regulations, to take evidence in appeals [illegible] required by law, to hold hearings, to submit annually to the general court, through the governor, a report including recommendations as to needed health legislation, and to discharge other duties required by law, but it shall have no administrative or executive functions.

There shall be in the state department of health such divisions as the commissioner of health may, with the approval of the public health council, from time to time determine. The commissioner of health shall appoint and may remove, with the approval of the public health council, a director to take charge of each division and shall prescribe the duties of each division. The compensation of directors of divisions shall be fixed by the commissioner of health within the limits of appropriations therefor, and subject to the approval of the governor and council.

The commissioner of health, with the approval of the public health council, shall from time to time divide the state into [illegible] health districts and shall appoint and may remove a district health officer for each district, with the approval of the public health council, at a compensation, subject to the approval of the governor and council, not exceeding $[illegible] a year. The district health officers shall not engage in any other occupation and shall give their entire time to the performance of their duties. The commissioner of health may, from time to time, order two or more of said district health officers to work in one district in order to study, suppress or prevent disease. Each district health officer shall have all the powers and perform the duties now provided by law for inspectors of health and further shall, under the direction of the commissioner of health, perform such duties as may be prescribed by, and shall act as the representative of the commissioner of health and under his directors shall secure the enforcement within his district of the public health laws and regulations. Said district health officers shall be graduates of an incorporated medical school admitted to practice in the Commonwealth, or shall have had at least five years' experience in public health duties and sanitary science.

. . . Present employees shall be continued in office until their successors are appointed and qualified, or until removed by the commissioner, provided, however, that no employee shall be removed who was appointed or is now employed under the provisions of the civil service laws and regulations, other than for cause, except division heads and district health officers, who shall be appointed as hereinbefore provided.

As the original bill was promoted by the Governor, it is assumed that he will sign it. The bill will then go into effect on Aug. 6, 1914.

Denver Municipal Bonds for Moffat Tunnel Declared Unconstitutional

The Colorado Supreme Court has denied the right of the City of Denver to issue bonds for driving a tunnel through the Continental Divide to be used by the Denver & Salt Lake R.R. and for the transportation of water and electric current (as described in ENGINEERING NEWS, Jan. 29, 1914). The city was given the right to proceed with this work and a commission was created by a constitutional amendment adopted May 20, 1913. After the issuance of the Tunnel Commission's report, the bonds were approved by the voters of the city on Feb. 17, 1914 (as noted in ENGINEERING NEWS, Mar. 5, 1914, page 541).

The court declared the tunnel contract unconstitutional and characterized it as a deliberate attempt to evade the constitution, coming within the fundamental inhibition against the use of municipal funds for the credit or benefit of private corporations. The counsel for the Tunnel Commission argued that there were four reservations taking the matter out of constitution limitations. The court overruled each of these, holding (1) that the city had made no provision to pay for the construction of conduits through the tunnel, that it had secured no right to use water from the western slope, and that it had not declared its intention of acquiring such right; (2) that the same facts held as to the use of the tunnel for the conveyance of electricity; (3) that, in regard to the city's reservation of right to mineral discovered in driving the tunnel, the city has no right to levy tax for the purpose of locating mineral claims; (4) that, in regard to the use of the tunnel by more than one railroad, no showing was made that any other road desired to use the tunnel.

The court concludes that these provisions in the contract were inserted in an effort to evade constitutional prohibition.

Notice has been given by the Tunnel Commission and City Attorney that an attempt will be made to recall the

decision under an amendment adopted in 1913, which permits a judical decision involving constitutional questions to be reviewed and recalled by a vote of the section of the state interested. In spite of this, it is reported that there seems no certainty of such an effort being supported by the Denver vote, and it is possible that the Supreme Court would step in again and deny the right of one part of the state to change a constitutional provision applying to the whole state.

Therefore, at the present moment, early completion of the project seems to hinge on the willingness of the railroad company to complete the construction of the tunnel without the city's coöperation.

The Strength of Lime Mortar*

The scanty data on strength of lime mortar are much amplified by test results of W. E. Emley and S. E. Young, presented in a paper under the above title. By mixing in the mortar a 1% solution of "Wool Blue R," the setting of the mortar can be observed in broken specimens; the dye colors the calcium carbonate blue, but leaves the hydrate colorless. In the broken specimens, a blue exterior shell was seen, showing the penetration of the atmospheric carbon dioxide, which converted the lime hydrate into hard carbonate.

A set of compressive and tensile tests made on various commercial limes in 1:3 mortar at 6 mo. age, in 2-in. cubes and standard briquettes, gave results tabulated below. The important feature is the higher strength of the dolomitic limes, shown near the bottom (low CaO content). The high-calcium mortars crush at 100 lb. per sq.in., while the dolomitic limes crush at 300 lb. per sq.in.

The high-calcium limes acquired strength somewhat earlier than the dolomitic limes, but at 1 mo. age the latter were 50% stronger in compression and continued to gain strength faster than the high-calcium limes.

Since lime mortar hardens from the surface inward, large cubes show lower strength than small cubes. At 3 mo., 6-in. cubes were only 1/3 to 1/4 as strong as 1-in. or 2-in. cubes. Prisms of equal cross-section, with different ratios of exposed surface to volume, showed much greater strength.

The strength of mortar increases with the fineness of the sand. Both high-calcium and dolomitic limes showed 2½ times as great a crushing strength with sand of 60 to 80 mesh fineness as with sand of 10 to 20 mesh. Excessive water weakens the mortar, but below a certain minimum of water, varying from 15% to 35% for the various lime-sand mixtures tried, there is a very great drop in strength.

Adding lime to portland-cement mortars, both neat and 1:3, did not weaken the mortar appreciably at ages up to 1 yr., provided the amount of lime did not exceed one-third the amount of cement. This applies to both compressive and tensile strength, and either air or water storage.

TABLE I. COMPRESSIVE AND TENSILE STRENGTHS OF LIME MORTARS

(Mixture 1 part lime to 3 parts river sand. Age 6 months).

*Abstract of paper presented before the American Society for Testing Materials, Atlantic City, June 29-July 3.

NEWS NOTES

A Wood Highway Bridge Collapsed under the load of a moving automobile near Dale, Mich., on June 30. The automobile came down a steep hill and onto the structure, through which it fell to a shallow stream 30 ft. below.

The Steamship "Invermore" Went Ashore near Brig Harbor, on the Labrador coast, on July 10. The "Invermore" is owned by the Reid Newfoundland Ry. Co. and carries passengers, mail and freight. She is a single-screw steamship, 250 ft. long, 30-ft. beam, built in 1881, and is commanded by Captain J. Kanel.

A Large Flywheel Burst in a cooperage factory of New York City, on July 6. Five minutes after the shop machinery was started the flywheel, 5 ft. 6 in. in diameter, burst. Many of the smaller machines were wrecked; but due to the early hour few men were at their places and only two were injured. A 300-lb. piece of the wheel was hurled through a window and through the wall of an adjacent tenement house.

A Sandy Hook Pilot Boat Was Sunk at the entrance of the Ambrose Channel, New York, recently by the United Fruit steamship "Manchioneal," outward bound in a fog. The crew of the pilot boat (the "New Jersey") was taken off by vessels in the vicinity. The "Manchioneal," of 1600 tons, continued on her voyage to Jamaica. The "New Jersey" was a 248-ton wooden vessel, 144 ft. long.

The First State-Aid Roads to be built under the new Illinois law in Logan County are to be of concrete, 10 ft. wide, with 8-ft. strips of waterbound macadam on the sides.

Work Begun on Hetch Hetchy Road—City Engineer M. M. O'Shaughnessy of San Francisco recently visited the Hetch Hetchy Valley personally to supervise the beginning of the first construction road to the dam site. Work was started on a road 8½ miles in length. It will first be used as a wagon road, but later railroad tracks will be laid upon it.

City Waste Collection and Disposal in Chicago is to be investigated by a special engineering commission, with a view to working out a system to be adopted by the city. The council has made an appropriation of $35,000 for the work and the necessary experimental plant and equipment. This is the result of the report of a former commission, which report has been given in abstract in our columns.

The Longest Tunnel in America—The Mount Shasta Power Corporation is pushing construction on a seven-mile tunnel to carry water from the Pitt River, in Shasta County, Calif., to the forebay of its projected power house. The tunnel so constructed is to be 7 ft. wide and 9 ft. high. Later it will be enlarged to a width of 16 ft. and a height of 19 ft. Crews are working at both ends, the aggregate length of the two sections now being a little over a mile. The entire length will be completed as a 7x9-ft. section before the bore is enlarged.

Systematic Sale of Inferior Cement Discovered in San Francisco—The Commissioners of the Board of Public Works of San Francisco have discovered that deteriorated cement is being disposed of in large quantities throughout that city. The yards of a prominent firm of contractors were inspected and sacks of the spoiled product found in abundance. The Commissioners have received reports that certain building foundations are crumbling away, which leads to the belief that a ring of dishonest dealers are systematically marketing a very inferior mixture

The City of Long Beach, Calif., is held responsible for the condition of its municipal pier, which collapsed on May 24, 1913 (see Eng. News, June 19, 1913, p. 1255), killing 11 persons and injuring some 2[illegible] more. In a test case brought before the Superior Court of the state, damages to the extent of $[illegible] were awarded to a man for the death of his wife in the accident. If the precedent holds, the city will be mulcted of several million dollars. It will be remembered that the pier in question was a timber structure of strikingly weak design and in a poor state of maintenance.

Federal Aid to Good Road Construction was provided for to the amount of $2[illegible] in the Shackelford bill passed by the House of Representatives some months ago. The bill has since been in the hands of the Senate Committee on Post Offices and Post Roads, of which Senator Bankhead, of Alabama, is chairman. A letter of Senator Bankhead's dated July 3, says:

The committee is diligently at work perfecting the bill and I have no doubt that in a few days a report will be made. The bill will probably be along the line of the discussions at the meeting of the United States Good Roads Association at St. Louis last November.

A District Water Supply Project for Cohoes, Waterford, Watervliet, Green Island, N. Y., and adjacent territory has been launched by the State Conservation Commission. This is the so-called Charlton project to use the waters of Aplaus Kill, Saratoga County, some 25 miles northwest of Albany. A dam would be constructed to create a 3000-million-gal. storage reservoir. The population of the proposed union district is 51,[illegible], with a present consumption of 6,300,000 gal. per day; provision is planned for 15,000,000 gal.

This scheme conflicts with the plans of the city of Watervliet to take a supply from the Normanskill at French's Mills, using waterpower to pump through the supply line. Watervliet has secured enabling legislation, but has yet to secure the approval of the Conservation Commission.

The Height of Buildings in Chicago is limited by ordinance to 2[illegible] ft. A special permit was asked recently for a hotel building 26[illegible] ft. high, on Michigan Ave. When this was refused, an ordinance was introduced to permit the construction of 26[illegible]-ft. buildings along Michigan Ave. where it fronts upon Grant Park and the lake. Fortunately this was rejected by the council, and it was shown very clearly that one cause of the great and increasing traffic congestion of Chicago is due to the tendency to confine the business district to a limited area by the construction of "skyscraper" buildings. The pressure for space is so great that office and mercantile buildings are now being built outside of the old central district and the Chicago, Burlington & Quincy R.R. has even put its new office building on the west side of the Chicago River.

The Right of the Illinois Highway Commission to Make Contracts for Material for road construction has been upheld by the state courts in a decision handed down the last week in June. To prevent skimping of cement and other material the Highway Commission has decided to purchase the materials and furnish them to contractors who are awarded construction contracts. According to press dispatches from [illegible], Ill., July 1, the suit involved was filed at Sycamore, [illegible] County, where attorneys representing certain taxpayers sought to enjoin the State Highway Commission from purchasing cement and other materials. The attorneys, who [illegible] were employed by a cement company which failed to get a contract from the commission, contended that [illegible] the new road law did not authorize the commission [illegible] to purchase materials that [illegible] cannot [illegible] make such purchases.

The Glasgow Dock Fire—It now appears that the [illegible] [illegible]

Interference with the U. S. Geological Survey [illegible] surveys and other work of the U. S. Geological Survey." Its provisions include the following: (1) the appointment of the annual appropriation for topographic surveys and water resources investigations among the several States on the basis of area and population; (2) the distribution of the field work within each State upon the recommendation of the majority of the congressional delegation; (3) the determination of the technical details of the topographic and hydraulic surveys by the Secretary of the Interior upon the advice and recommendation of the majority of the Congressional delegation from each State.

The scale for maps would be decided by each State, so that there would be no uniformity, and the general control of the work would be political (and of the pork-barrel variety) instead of scientific. The Western Society of Engineers and the Illinois Society of Engineers and Surveyors have sent protests to Congress against the passage of the bill. They refer to the high quality of the work of the U. S. Geological Survey, and the resolution of protest adopted by the first-named Society states that this bill is fundamentally wrong in that it substitutes the judgment of a majority of the Congressional delegation for that of the Director of the Geological Survey on matters which are purely technical.

An $85,000 Error in a $322,000 Bid for a bridge contract came very near proving disastrous to a firm of contractors, which was awarded a contract for the construction of the Central bridge at Lawrence, Mass. Shortly after the bids were tabulated, the contractor informed the bridge commissioners that he had made a mistake in his calculations aggregating about $85,000, the accepted bid being about $322,000. The next lowest bid was something like $101,000 higher than the one for which the contract was awarded. Subsequently, questions were raised as to the appropriation of the money for the construction of the bridge and the commissioners were given to understand that owing to certain legal questions the contractor would not undertake the contract. Legal proceedings were begun by him to prevent the bridge commissioners from enforcing the contract. Subsequently, however, an arrangement was made between the commissioners and the contractor whereby the foundation and excavation work to spring lines, including what is called in the contract "Class C concrete," should be done as force account work, namely, the total cost including labor and materials and use of plant as agreed upon by the consulting engineer and the contractor, plus 10%. R. H. Davis, Consulting Engineer, advised the commissioners to make the above change in the contract. It is estimated that the additional expense to the city will not exceed $1[illegible] over the bid submitted by the contractor. On the above basis a contract has been signed, a bond has been furnished and the construction of the bridge begun. [Information from John J. Donavan, Chairman of Lawrence Bridge Commission.]

The Ohio Conservancy Act is still awaiting a final interpretation by the courts of the state. The present status of the act is reported by the Dayton Citizens' Relief Commission to be as follows:

On June 3 the Court of Appeals rendered a decision upholding the constitutionality of the Conservancy Act of Ohio in all major points. The laws of Ohio provide that an appeal may be taken on error from a decision of the Court of Appeals within 70 days after the decision is rendered. In making its decision the Court of Appeals granted to the contestants a stay in its mandate to the Court of Common Pleas, or Conservancy Court, ordering the petition for the forming of the Miami conservancy district to be heard at once. This stay was granted until July [illegible] in order that the contestants might have time to decide whether they would take the case to the Supreme Court of the state on error before the Conservancy Court made any preparation to begin its hearing upon the original petition.

The mandate of the Court of Appeals ordering the case back to the Conservancy Court was filed July 1. On July [illegible] attorneys for the contestants announced, after consultation, that they would take an appeal to the Supreme Court on error. They further [illegible] that they desired to print the [illegible] [illegible] would require they said about three weeks. As the [illegible] period from the date of the Appellate Court's decision gives them until August 12 it is not likely that formal action in the appeal will be taken until the latter date. It is believed that once the case is brought before the state Supreme Court there will be little delay in [illegible] hearing, as the Ohio Conservancy Act was passed as an emergency measure and specifically provides that it shall be given precedence.

The "Storstad" Was Blamed for the loss of the "Empress of Ireland" by the Commission of Inquiry headed by Lord Mersey in its report [illegible] at Quebec, Que., on July 11. The "Empress of Ireland" of the Canadian Pacific [illegible] was rammed by the collier "Storstad" in the St. Lawrence River

on May 29 and sank near Father's Point with a loss of 1014 lives. Third Officer Tuftenes of the collier is held directly responsible, in the following words:

We regret to have to impute blame to any one in connection with this lamentable disaster, and we should not do so if we felt that any reasonable alternative was left to us. We can, however, come to no other conclusion than that Mr. Tutenes was wrong and negligent in altering his course in the fog, as he undoubtedly did, and that he was wrong and negligent in keeping the navigation of the vessel in his own hands, and in failing to call the captain when he saw the fog coming on.

The second important finding was that the disaster was not due in any way to any special characteristics of the St. Lawrence River. "It was a disaster which might have occurred in the Thames, in the Clyde, in the Mersey, or elsewhere, in similar circumstances."

The following is quoted from the report:

After carefully weighing the evidence we have come to the conclusion that Mr. Tuftenes was mistaken if he supposed that there was any intention on the part of the "Empress of Ireland" to pass port to port, or that she, by her lights, manifested the intention of doing so; but it appears to us to be a mistake which would have been of no consequence if both ships had subsequently kept their courses.

Shortly after the ships came into the position of green to green, as claimed by Capt. Kendall, or red to red, as claimed by Mr. Tuftenes, the fog shut them out from each other, and it is while they were both enveloped in this fog that the course of one or the other was changed, and the collision brought about. From the evidence adduced on behalf of both vessels it is plain that before the fog, and when they last saw each other, there was no risk of collision, if each kept her course.

It is admitted that those on board the "Storstad" did that which in ordinary circumstances would change her course, and they did it in the fog shortly before the accident. They ported and they hard-a-ported the "Storstad's" helm. Assuming that she answered to this hard-a-ported helm, the effect would be to bring her head around to starboard in the direction of the "Empress of Ireland," and if she continued in the direction of the "Empress of Ireland" under this helm the effect would be to bring her into collision with the "Empress of Ireland."

It may be asked what induced the men in charge of the "Storstad" (Mr. Tuftenes and Mr. Saxe) to port and to hard-a-port the helm. The explanation is fairly plain. They believed, wrongly as it turned out, that the "Empress of Ireland" was passing their ship red to red. They wanted, as Mr. Turtenes said to Mr. Haight when he gave his first version of the story, "to make sure of ample room," and they ported in order to secure it. Unfortunately the "Empress of Ireland" was passing green to green, and so far from the porting securing more ample room, it brought the vessels into closer proximity, and then into collision.

The Commission of Inquiry is composed of Lord Mersey, formerly presiding justice of the British Admiralty Court; Sir Adolphe Routhier, of Quebec; and Chief Justice McLeod, of New Brunswick.

PERSONALS

Mr. F. C. Baluss has been appointed Engineer of Bridges and Buildings of the Duluth, Missabe & Northern R.R., with headquarters at Duluth, Minn.

Mr. Harry J. Marks, M. Am. Soc. M. E., Manager of the New York City office of the American Engine & Electric Co., has been promoted to be Sales Manager of the company.

Mr. J. N. Olson, Jun. Am. Soc. C. E., formerly Office Engineer of the J. C. Field Engineering Co., Denison, Tex., has been appointed Assistant City Engineer of Denison

Prof. H. C. Ramsower, of the college of agriculture of the Ohio State University, has been appointed the head of the new department of agricultural engineering of the college.

Mr. W. C. Barrett, formerly Special Road Engineer, Grant District, Jacksonburg, W. Va., has been appointed Division Engineer of the Lehigh Valley R.R., with office at Sayre, Penn.

Mr. R. F. Kelker, Jr., recently Assistant Engineer, Division of Valuation, Interstate Commerce Commission, has been appointed Traction Expert of the Bureau of Public Service of Chicago, Ill.

Mr. A. B. Copley, Division Superintendent of the Chicago, Rock Island & Pacific Ry., at Little Rock, Ark., has been promoted to be Assistant General Manager, with headquarters at El Reno, Okla.

Mr. W. A. Whitney, former Division Superintendent of the Southern Pacific Ry. at Sacramento, Calif., has been appointed General Superintendent of the Oregon Short Line R.R., with office at Pocatello, Idaho.

Mr. Hans August Evald Conrad von Schon, M. Am. Soc. C. E., has resigned as Consulting Engineer in charge of construction of the new water-works of the village of Highland Park, a suburb of Detroit, Mich.

Mr. Charles F. Brush, M. Am. Inst. E. E., of Cleveland, Ohio, has been awarded the Edison Medal of the American Institute of Electrical Engineers for his inventions and developments in electric arc lighting.

Mr. M. J. Butler, M. Am. Soc. C. E., of Montreal, Que., has been appointed a valuation expert to examine into the physical aspects of the Montreal Water & Power Co., to succeed Mr. Ernest Belanger, M. Can. Soc. C. E.

Mr. Lincoln Breedlove, of Martinsville, Ind., a recent graduate of the University of Illinois, has been appointed Supervisor of and Lecturer in mechanical enginering courses at Roberts University, Constantinople, Turkey.

Mr. E. L. Adams, recently Assistant Signal Engineer of the Lake Shore & Michigan Southern Ry., has been appointed Senior Signal Engineer of the Division of Valuation, Interstate Commerce Commission, at Chattanooga, Tenn.

Mr. E. C. Noble, of Houston, Tex., has been elected President of the Altus, Lubbock, Roswell & El Paso R.R., a new railway which has 60 miles of road in operation and 86 miles of roadbed graded through the Panhandle of Texas.

Mr. George Weston, recently removed by Mayor Harrison of Chicago, Ill., from his position as the city's representative on the Board of Supervising Engineers (in charge of traction work), retains his position as Chief Engineer of the Board.

Dr. Robert H. Whitten has resigned as Librarian-Statistician of the Public Service Commission, First District, New York State, to become Secretary of the committee on city plan of the Board of Estimate and Apportionment of New York City.

Mr. I. M. de Varona, M. Am. Soc. C. E., whose resignation as Chief Engineer of the Department of Water Supply, Gas & Electricity of the City of New York was noted in our issue of July 9, has been granted a pension of $3500 per annum, or 35% of his former salary.

Mr. J. W. Mulhern, former Superintendent of the Pere Marquette R.R., at Grand Rapids, Mich., has been appointed Superintendent of the Northern division of the Chicago Great Western R.R., with headquarters at St. Paul, Minn., succeeding Mr. W. B. Causey, resigned.

Mr. Carl Rankine has been appointed Locating Engineer of the San Francisco municipal railway to be built from the San Joaquin Valley to the Hetch Hetchy damsite. Mr. Rankine has had several years' experience in location surveys for the Southern Pacific Co in California, Oregon and Arizona.

Mr. T. H. Sears, Division Superintendent of the Atchison, Topeka & Sante Fé Ry., at Marceline, Mo., has been promoted to be General Superintendent with headquarters at Armarillo, Tex. He is succeeded as Division Superintendent at Marceline by Mr. R. H. Allison, former Trainmaster at Emporia, Kan.

Maj. R. W. Leonard, M. Can. Soc. C. E., has resigned as Chairman of the Canadian Transcontinental Railway Commission in order to devote his whole time to private business. The duties of the commission are to be taken over by the Commissioner of Railways, under whose supervision the construction work now under way will be completed.

Mr. Otto Holstein, formerly Superintendent of Transportation of the Guayaquil & Quito Ry. in Ecuador, has been appointed Superintendent of Transportation of the San Antonio, Fredericksburg & Northern R.R., with headquarters at Fredericksburg, Tex. Mr. Holstein was formerly in charge of operation of the Central Ry. of Peru.

Mr. John J. Brown, President of the village of White Plains, N. Y., has been appointed Manager of the recently completed Bronx Valley Trunk Sewer, at a salary of $2500 per annum. The sewer has been completed, but is not in operation because the city of Yonkers, N. Y., has obtained an injunction against the building of a disposal works within that city.

Mr. Alexander Johnson, Assoc. M. Am. Soc. C. E., has resigned as Chief Engineer of the Department of Bridges, New York City. Mr. Johnson has not been in good health for some time. He is a graduate of Sheffield Scientific School, Yale University, and has been connected with the New York City Bridge Department for 18 years. He is succeded by Mr. Austin Lord Bowman, M. Am. Soc. C. E., as noted elsewhere.

Mr. Albert J. Stone, General Manager of the Erie R.R., at New York City, has been elected Vice-President in charge of operation, with headquarters at New York. Mr. Stone entered the service of New York, Lake Erie & Western R.R. in 1888 as a messenger. With the exception of two years, 1903 to 1905, when he was General Superintendent of the Delaware & Hudson R.R., Mr. Stone has been continuously in the employment of the Erie R.R.

Mr. R[illegible] W[illegible], formerly Chemist and Engineer of Tests of the M[illegible] R.R., has leased the railway company's laboratory, which was used for testing materials during the construction of the Detroit River tunnel, new Union Station and subsequent improvements at Detroit. The laboratory will now be conducted under the name of the [illegible] Testing Laboratory, and will be used by Mr. Perry for the general practice of chemical, inspecting and testing business.

Mr. Daniel F. Fulton, for the past six years Assistant City Engineer of Yonkers, N. Y., has been appointed City Engineer, succeeding the late Samuel L. Cooper, M. Am. Soc. C. E., who died a year ago. Mr. Fulton is a graduate in civil engineering of Cornell University, class of 19[illegible], and was first employed as Assistant to the late George W. Rafter, M. Am. Soc. C. E., Consulting Engineer, of Rochester, N. Y. Later he was with the Buffalo, Rochester & Pittsburgh R.R. In 1[illegible] Mr. Fulton was appointed Assistant Engineer in the New York State Engineers' Department. From 1906 to 1908 he was in charge of Residency No. 1 on the Champlain Canal.

Mr. James H. Hustis, President of the New York, New Haven & Hartford R.R., will resign, it is reported, Aug. 15, to become President of the Boston & Maine R.R., which is to be entirely separated from the New Haven system. He succeeds Mr. Morris McDonald, who returns to his former office as President of the Maine Central R.R. Until his election as President of the New York, New Haven & Hartford R.R., Mr. Hustis was Vice-President and operating head of the Boston & Albany R.R., so that there is probably no railway man in the country more familiar with New England conditions, although few of Mr. Hustis' contemporaries are likely to envy him on account of his new office. According to the recently enacted law of Massachusetts the New Haven system must sell its holdings of Boston & Maine R.R. stock within three years, the State of Massachusetts reserving the right to buy during or after that time.

Mr. Austin Lord Bowman, M. Am. Soc. C. E., Consulting Engineer, New York City, has been appointed Chief Engineer of the Bridge Department of the City of New York, succeeding Mr. Alexander Johnson, Assoc. M. Am. Soc. C. E., resigned. Mr. Bowman is a graduate of Yale University, class of 1883. Following his college course he began engineering work and in 188[illegible] was employed in the city engineering department of St. Paul, Minn. Later he was with the engineering departments of Minnesota & Northwestern R.R. and the Chicago, St. Paul & Kansas City R.R. Mr. Bowman returned East in 1887 to join the engineering staff of the Kings County Elevated R.R. in Brooklyn, N. Y. From 1887 to 1890 he was with the Norfolk & Western Ry., and from 1890 to 1895 he was Engineer and Superintendent of Construction for the American Bridge & Iron Co. of Roanoke, Va. In 1897 he opened an office in New York City as Consulting Engineer. From 1901 to 1907 he was Consulting Engineer of the Central R.R. of New Jersey, and since 1907 Consulting Engineer of the New York City Department of Bridges.

OBITUARY

[illegible]

[illegible]

[illegible]

[illegible]

... St. Louis Ry., died at Hot Springs, Va., July 11. He was born in Harrison, Maine, in 1842, and when 28 years old was made President of the Indianapolis, Cincinnati & Lafayette R.R.; later he was Receiver for the same railway. He was President of the reorganized company, and again Receiver for it, when it failed a second time in 1876. He was subsequently President of the reorganized and consolidated railways which became the Cleveland, Cincinnati, Chicago & St. Louis Ry. From 1888 to 1900 Mr. Ingalls was also President of the Chesapeake & Ohio Ry.

ENGINEERING SOCIETIES

COMING MEETINGS

OHIO ELECTRIC LIGHT ASSOCIATION.
July 16-19. Annual convention at Cedar Point, Ohio. Secy., D. L. Gaskill, Greenville, Ohio.

AMERICAN ASSOCIATION OF RAILROAD SUPERINTENDENTS.
Aug. 20-21. Annual meeting in New York City. Secy., F. H. Harman, Room 101, Union Station, St. Louis, Mo.

AMERICAN PEAT SOCIETY.
Aug. 20-22. Annual meeting at Duluth, Minn. Secy., Julius Bordollo, 17 Battery Place, New York City.

AMERICAN BOILER MANUFACTURERS' ASSOCIATION.
Sept. 1-4. Annual convention in New York City. Secy., J. D. Farasey, E. 37th St. and Erie Ry., Cleveland, Ohio.

AMERICAN MINE SAFETY ASSOCIATION.
Sept. 7-10. Annual meeting in New York City. Secy., H. M. Wilson, Bureau of Mines, Pittsburgh, Penn.

NATIONAL ASSOCIATION OF PORT AUTHORITIES.
Sept. 8-10. Annual convention in Baltimore, Md. Secy., Wm. Joshua Barney, 29 Broadway, New York City.

ROADMASTERS AND MAINTENANCE OF WAY ASSOCIATION OF AMERICA.
Sept. 8-11. Annual meeting at Chicago, Ill. Secy., L. C. Ryan, Sterling, Ill.

MASTER CAR AND LOCOMOTIVE PAINTERS' ASSOCIATION.
Sept. 8-11. Annual convention in Nashville, Tenn. Secy., A. P. Dane, Reading, Mass.

NEW ENGLAND WATER-WORKS ASSOCIATION.
Sept. 9-11. Annual convention in Boston, Mass. Secy., Willard Kent, Narragansett Pier, R. I.

INTERNATIONAL ASSOCIATION OF MUNICIPAL ELECTRICIANS.
Sept. 15-18. Convention in Atlantic City, N. J. Secy., Clayton W. Pike, Electrical Bureau, Philadelphia, Penn.

ILLUMINATING ENGINEERING SOCIETY.
Sept. 21-2[illegible]. Annual convention in Cleveland, Ohio. Secy., Joseph D. Israel, 29 W. 39th St., New York City.

RAILWAY SIGNAL ASSOCIATION.
Sept. 22-24. Annual convention in Bluff Point, N. Y. Secy., C. C. Rosenberg, Times Building, Bethlehem, Penn.

Atlantic Deeper Waterways Association—The eighth annual meeting of the Association will be held in New York City, Sept. 9-12. After the first day's session an inspection of New York harbor and of the New York and New Jersey waterways will be made. For the remainder of the convention the delegates will be housed aboard the Hudson River boats, on which the remaining sessions will be conducted. Representative J. Hampton Moore is President of the Association.

American Peat Society—The eighth annual meeting will be held Aug. 20-22 at the Commercial Club, Duluth, Minn. There will be an excursion to two peat bog districts some [illegible] miles north of the city, in one of which large drainage ditches are being cut to prepare the land for agricultural use. The papers will cover the cultivation and drainage of peat lands and the commercial uses of peat. Some of the papers are as follows: "The Peat Gas Producer," F. [illegible], Ottawa, Can.; "The Possibilities of Peat in [illegible]," Prof. [illegible], University of Minnesota; "Converting Peat into Fuel," Charles A. Davis, U. S. Bureau of Mines; "Peat Briquettes," [illegible]; "Briquettes from Peat and [illegible]," Robert [illegible], [illegible], Calif.; "The [illegible] Machine," [illegible]; "[illegible] of Machinery to Peat Deposits," L. A. [illegible]; "[illegible] a Peat Bog for Fuel Making," [illegible]; "Peat Lands in Minnesota and Wisconsin," Prof. J. T. Stewart, University of Minnesota; "The Peat Situation in Minnesota," [illegible]; "[illegible] of Peat in America," [illegible], New York.

Other papers will deal with the peat industry in England, Ireland and Russia. An exhibit of peat, peat products, cultivating machinery, etc., photographs of works, and other matters pertaining to peat development will be displayed at the rooms of the Commercial Club, Aug. 19-Aug. 22. Further information may be had from Julius Bordollo, Secretary, American Peat Society, 17 Battery Place, New York, N. Y.

Engineering Literature

CONTENTS

CORRESPONDENCE

A Book Purchaser on Title-Page Dates

Sir—In your issues of Dec. 18, 1913, Jan. 15, Feb. 12, and Mar. 19, 1914, you comment upon "Title-Page Dates," particularly upon the misrepresentation involved in a change of title-page date when there is substantially no change in the text.

May I call your attention to a flagrant case of such misrepresentation? I refer to "Electric Power Conductors," by Del Mar, "Second Edition Revised." I ordered this book, misled by the advertisement, thinking it to be a new edition, but in ordering it I warned the company supplying it that I should return it if it were not really a second edition, stating that I had frequently been swindled by fake second editions.

My attention was first attracted by the preface to the "second edition," signed by the author, reading as follows:

> The specifications for rubber insulation are radically different from those of the first edition and represent the results of a great deal of investigation and research. Other changes of more or less importance will be found on nearly ten (10) per cent. of the pages of the book.

This led me to inspect the book with some care. The first inspection revealed no changes other than those in the specifications for rubber insulation, but a further examination made with considerable care brought to light the following changes:

On pp. 13, 46, 49, 101, 124, 302 and 307, the addition of a footnote on each.

Pages 82, 83 and 251, rewritten in part.

Page 294, formulas changed.

Pages 317, 318 and 319 rewritten.

While I am not prepared to say that this covers absolutely every trifling change in the book, yet I believe it does substantially. You will note that there are practically no changes in the book save those referring to the changes in the "Rubber Specifications," which are included in pp. 189-92 and pp. 317-19.

Under these circumstances, it is difficult to see what justification there is either for the preface to the "second edition" or the change in the title page and the caption "second edition revised." The book is not a second edition; it is a first edition with very slight revisions and it is a gross misrepresentation to pretend that it is anything else.

I have frequently in the past been deluded into buying valueless technical books by practices of this kind, and I think it time that a strong protest be made against this sort of thing.

Cary T. Hutchinson.

60 Wall St., New York City,
June 19, 1914.

A Handbook of Fan Engineering

Sir—The writer is much disappointed with the review (Engineering News, June 18, 1914), which you have given to the "Fan Engineering Hand Book," published by the concern with which he is associated. He feels that your remarks convey a wrong impression to the reader and, inasmuch as the company is selling the book at $3 per copy, he cannot but feel that there will be confusion created in the minds of those of your readers who may see the advertisements of this work.

The writer must take exception to your statement that it is partly fundamental theory, partly a statement of common practice and much from the company's files, not because these items are not included, but because your comment implies there is nothing else to the work. There is included in this book much that is new to the fan engineer and it is information which is not limited in application to one concern's apparatus. Therefore it is left that the claim is substantiated for the book as a decided step forward and to be recognized as a true text or reference book on the subject.

H. C. Rice.

Buffalo Forge Co., Buffalo, N. Y., July 7, 1914.

A puzzling bit of railway English is circulating at the rate of some hundreds of miles a day on a railway south of Mason and Dixon's line. It reads:

> Passengers are respectfully requested to keep their feet off the seats.
> Conductors are instructed not to permit this.

Notwithstanding this sign, the seats did not look footworn nor the passengers nor conductor careworn.

REVIEWS AND NOTES

Irrigation in Egypt

Reviewed by F. H. Newell*

EGYPTIAN IRRIGATION. By Sir W. Willcocks, Formerly Adviser to the Ministry of Public Works, Constantinople, Managing Director of the Daira Sanieh Company, and Director-General of Reservoir Studies, Egypt; and J. I. Craig, Director, Computation Office, Director Meteorological Services, Egyptian Survey Department, now Controller, Department of General Statistics; with an Introduction by Sir Hanbury Brown, formerly Inspector General of Irrigation, Egypt. Two volumes. Third edition. London: E. & F. N. Spon, Ltd. New York: Spon & Chamberlain. Cloth; 7x10 in.; pp. xxxiv + 881; 188 illustrations and 51 folding plates. 15, net, per set.

American engineers, particularly those having to do with water-supply, irrigation or drainage, will find much of interest in the recent, the third, edition of "Egyptian Irrigation" prepared by Sir William Willcocks and J. I. Craig. This interest is aroused both by the similar and by the contrasting conditions between those in Egypt and in the United States.

Under the head of similar conditions which afford lessons of direct application are the problems of storage of flood waters, of disposing of silt, of guarding against excessive use of water and consequently of alkaline conditions, of the necessity of fertilization, not merely for immediate increase of crop production but also as saving waste of water, and in pumping water both as a supplemental supply and as the only source of irrigation water.

The contrasting conditions which are also valuable, though of less direct application, are the regularity of flow of the river, the unity of the problem—as the water is derived from the one drainage area—the method of application of the water in great basins, the labor conditions, the character of land ownership, and the financing of the works and recovery of the cost by taxation.

The book itself, of two volumes, aggregating nearly 900 pages, with plates and illustrations, is largely a compilation of official reports. While this form of presentation has its advantages in showing the development of ideas and in affording opportunity of reference to these early reports, yet to a stranger it has the great disadvantages of repetition, of unnecessary elaboration, and of more or less confusing arrangement. The man who thoroughly understands the subject can readily add to his knowledge through such profusion of detail and by occasional divergence of view expressed, but to a busy engineer the task of digging out some of the larger elementary facts is discouraging. The value of the book could be greatly increased to the engineering profession in general if brief elementary explanations were given as to the local customs and terms, also by having simple conversion tables showing the relation between the units of quantity, area and values, with those habitually employed in other countries, notably in the United States.

Surmounting these barriers to easy progress, however, the irrigation engineer finds much "pay-dirt" scattered through the book. It begins with a general description of Egypt and the Nile, then takes up the basin irrigation which has been practiced for thousands of years, followed by more modern perennial irrigation which has become possible through the building of barrages, or as we term them diversion dams. Next comes the important subject of drainage and land reclamation, together with the engineering details of the barrages, storage reservoirs, flood protection and agricultural conditions. One of the most striking of these is a statement repeated from an early report, "The Nile in 1904," as follows:

> It would be a healthful innovation, indeed, if the provision of suitable manures were to be considered as an essential part of a project for providing perennial irrigation. The day is not far distant, I believe, when governments which provide irrigation works will also provide manures, and sell the water and the manures together, one being as essential as the other. I know well, from observation, that a well manured field needs only half the water that a poorly manured field does, and in years of drought and scarcity manures almost take the place of irrigation. Why should there not be a manure rate as well as a water rate? Here in Egypt, the numerous ruins of old-world cities have hitherto provided manure for a great part of the perennially irrigated lands, but these are being fast worked out and other sources must be sought for. Farmyard manure will never suffice for the intense cultivation in this country.

Compared with conditions in the United States, irrigation in Egypt appears to be a relatively simple problem, although one of great magnitude. To the outsider it appears at first glance that all that is needed is ample money to build a few big storage dams and to divert the water into large canals from which it could be distributed over millions of acres. Going deeper into the matter, however, it seems that this broad requirement is complicated by a number of conditions, not at first apparent even to the men who have been on the ground. The fundamental difficulty encountered throughout the world is that whenever an ample supply of cheap water is provided by storage the lands are over-irrigated quickly and a large part of them ruined by excessive application of water. In the United States this danger is being met by delivering water for irrigation on a measured basis; that is to say, by selling the water or charging the cost of delivery on the basis of so much per acre-foot. In this, the ordinary commercial rules are followed, as in the sale and delivery of coal or any other commodity. Through the *pocket nerve* it is thus possible to secure economy of water and save good land from destruction, even where every other argument fails.

In storing and diverting the water of the Nile there have arisen not only the evils of swamping the lands and of accumulating salts or "alkali" on the surfaces, but also the deprivation of much of the land of the rich red water renowned throughout all time for its fertilizing qualities. It is not enough merely to obtain water for the land; to secure the highest results the water must carry and leave on the fields the red mud which comes mainly from the Blue Nile and other tributaries rising in the mountains of Abyssinia. These floods of red water occur with marvelous regularity and have been the cause of the agricultural success in the Nile Valley for upward of 7000 years. The time of occurrence of the red water is relatively short; throughout the rest of the year the water, though valuable, does not bring with it the elements of fertility comparable with those of the red-water period.

It is obvious that this rich, red water cannot be held in storage but at the time of occurrence must be passed on directly to the fields and the distribution system so arranged that not only will ample water come to the fields but there must be provision for rapid escape of much of the water after it has deposited the red mud on the fields. This is a condition, emphasized by the present book, which has not been fully appreciated even by some of the

*Director, United States Reclamation Service, Washington, D. C.

administrative officers who have had responsible charge of the planning and operation of the works. They have either overlooked or minimized the value of this red water or have not provided ample capacity for bringing it to the fields or for carrying the water away after it has deposited its burden.

The problem of the most complete use of the Nile is further complicated by certain peculiar topographic conditions which are not usually appreciated. The problem is not a simple one of storing all the water possible in large reservoirs near the headwaters and letting it down when needed. The best reservoir sites do not occur where the water can be stored to best advantage. This is almost invariably the case in every country. In addition, is the peculiar topographic condition that down along the lower course of the river shortly before it branches at the delta, there is in the desert to the west of the river a series of deep depressions the bottoms of some of which are below sea level. In this respect the contour of the country is somewhat similar to that of the Salton Sea area in Imperial County, southern California, west of and above the delta of the Colorado River.

It is possible to divert the floods of the Nile, as in the case of the Colorado River, to these basins in the west. This is by no means a modern discovery. The conditions were not only known to the ancients but the early Egyptian engineers and rulers actually built works for diverting the high Nile floods into these basins, thus protecting the lower lands from inundation. These works were of such magnitude that it has long been a question as to whether the remains now existing were actually built by the hand of man. They rival the building of the pyramids and far surpass these in grasp of engineering laws and in value to the country.

The ancient rulers not only diverted the extraordinary floods for purposes of preventing inundation but by filling one of these basins to the level of high Nile were able to draw back into the lower river a certain amount of water when the floods subsided. In this respect they had certain advantages over the modern plans which contemplate using one of these basins for escape or relief to the extraordinary floods but which on account of the topography cannot return the water to the river at low stages as was formerly done. The basin which was then used and which could deliver back to the river some of the stored water, is now being cultivated to an extent that it is not practicable to utilize it again for water storage.

Passing from these larger engineering conceptions, the book deals with many important administrative problems, notably with reference to control of the use of water to prevent deterioration of the land. In this respect, the Egyptian government is autocratic and can and must enforce the regulations devised by its experienced advisors. It need not await the slow education of the great body of water users before adopting those practices which experience has shown are necessary for the general prosperity. The book emphasizes the well known saying that "the Egyptian question is the irrigation question; without irrigation there can be no Egyptian people; certainly no civilization in Egypt."

⁂

Bulletins on the Results of Spirit Leveling in Kansas, Washington and Oregon, from 1896 to 1913, inclusive, have been published recently by the U. S. Geological Survey, Washington, D. C.

THE MUNICIPAL YEAR BOOK OF THE UNITED KINGDOM for 1914—Founder and Director, Robert Donald. Editor, Albert E. Cave. London: The Municipal Journal, Ltd., Sardinia House, Sardinia St., W. C. Cloth; 6x9 in.; pp. 1193. 15 Shillings, net.

A vast amount of information regarding the municipalities and municipal activities of England, Wales, Scotland and Ireland is given in this thick volume. Besides lists of council members, "chief officers" and a variety of descriptive, historical and general information under each place listed, there are given many facts and figures regarding water-works, gas works, electricity supply, tramways, refuse and sewage disposal, housing, town planning, baths and wash houses local taxation, financial transactions of municipalities for 1912-13, and other subjects. This plan is convenient when looking for information on a single topic, as water-supply, but it scatters the information for a given city all through the book. However, such a storehouse of municipal data is a boon, however arranged, and this volume is systematically arranged and well indexed. Services rendered by private companies are not even mentioned.

⁂

The 1913 American Year Book

THE AMERICAN YEAR BOOK: A Record of Events and Progress, 1913—Edited by Francis G. Wickware, under Direction of a Supervising Board Representing National Learned Societies. New York and London: D. Appleton & Co. Cloth; 5x8 in.; pp. xx + 892. $3.

An incorporated Supervisory Board of 39 members, representing officially or unofficially 39 learned societies, has directed 128 contributors in the preparation of this, the fourth, issue of "The American Year Book." The large mass of information given is classified and subclassified under 35 departments.

The departments of most direct interest to the readers of this journal are: Municipal Government; Public Resources and Public Works; Public Services; the Mineral Industries; Trade, Transportation and Communication; Engineering, Mathematics and Astronomy; and Chemis- and Physics. In addition, history, government, foreign affairs, population and a variety of other large subjects are treated.

In such a reference annual as this, of course, the information given in any one department is not designed for specialists in that field, but rather for those in other fields and for laymen. From this viewpoint the 35 pages devoted to Engineering and the 8 pages given to Civil Engineering may perhaps be considered sufficient, at least in relation to the 860 pages which comprise the book. It should be noted, however, that many of the subtopics treated under Engineering appear in one to three or four departments—partly as additional information and partly as repetition.

Where space limitations compel such light touching on the high peaks as is noticeable in this volume the departmental repetition seems questionable. As an example of questionable repetition the proposed Hetch Hetchy or Tuolumne River water-supply for San Francisco may be cited. This has a short paragraph under Legislation (p. 27), nearly a page under Public Resources and Public Lands (p. 270), a paragraph under Public Services (p. 304), and another paragraph under Water-Supply (p. 581). Altogether, Hetch Hetchy gets considerably more than a page in these four places. Some of the information under Civil Engineering is both duplicated and seemingly contradicted under Public Services, in the references to the killing of the New York

water-filtration project, and a resume of water disinfection by chlorination appears under both Civil Engineering and Sanitary Chemistry, with somewhat misleading statements in each place. The blemishes cited are minor ones and might not deserve mention if they did not occur in duplicated matter.

The mystery surrounding the non-representation of the American Society of Civil Engineers on the Supervisory Board still remains unexplained. It is all the more noticeable when one finds four or five other national engineering societies and the American Institute of Architects represented.

Tests of Bond between Concrete and Steel

TESTS OF BOND BETWEEN CONCRETE AND STEEL—By Duff A. Abrams. Bulletin 71, Engineering Experiment Station, University of Illinois, Urbana, Ill. Paper 6x9 in.; pp. 238; illustrated. $1.

The nature and extent of the bond between reinforcing and concrete in reinforced-concrete beams has been the subject of experimental investigation ever since reinforced concrete has come into very extensive use, and a number of series of such experiments have been reported in serial publications and in laboratory bulletins. The bulletin before us, however, is by far the most elaborate of any such publications we have seen, and the tests on which the bulletin is based seem to be more extensive than any hitherto made. The bulletin is by D. Abrams, Associate in Theoretical and Applied Mechanics of the Engineering Experiment Station at the University of Illinois, and the tests on which the bulletin was based were made in the Laboratory of Applied Mechanics of the University of Illinois between 1909 and 1912, under the direction of Prof. A. N. Talbot. The experiments were made on straight pull-out specimens and on beams of various design and dimension, with different types and sizes of reinforcement.

The report of the tests is very much too long to abstract here, and the results obtained are equally extensive. In fact, the author requires 101 paragraphs to summarize the results as analyzed by him. We give below, however, the various headings under which the investigations were made, so that the reader may get some idea of the extent of the investigation.

Under the pull-out tests the subheads are: The effect of variations in the dimensions of pull-out specimens, the effect of shape and section and condition of surface of bar, effect of condition of storage, bond tests with deformed bars, effect of age and mix, effect of anchoring ends of bars, and miscellaneous tests.

Under reinforced-concrete beam tests, each of the three years' tests are taken up separately, under such headings as bond with plain round bars, bond with deformed bars, comparison of bond resistance in beams and in pull-out tests, effect of vertical stirrups on bond resistance, effect of depth of concrete below the reinforcement, effect of span lengths, effect of length of overhang and ends of beams, theory of reinforcement, effect of repeated and sustained load on beams, slip of reinforcing bar at [illegible] [illegible] in beams, distribution of bond and tensile stress along the bar, relation of slip of bar to diagonal tension cracks, influence of slip of bar upon beam deflection, critical bond stresses, and working stresses for bonds.

Enough has been given, we are sure, to indicate to the reader how valuable a contribution to the theory of reinforced-concrete design Mr. Abrams and his associates have made.

⌘

Coast Sand Dunes

COAST SAND DUNES, SAND SPITS AND SAND WASTES—By Gerald O. Case, Consulting Engineer for Coast Works. London: St. Bride's Press, Ltd. Cloth; 5x8 in.; pp. 162; 43 illustrations. 5 shillings, net.

A large part of the shores of the oceans and large lakes of the world, is lined with sand, which, under natural conditions, is a moving body, subject to the forces of wind and wave, and often a serious danger to inshore life and structures. In the older countries of the world considerable effort has been made to fix this sand and to prevent its movement in so far as possible. This has been done by the construction of groins extending out into the water and by the planting of various local trees and bushes on the foreshore itself. Some of this work has been done in the United States and in England, but most of it in Continental Europe.

So far as we know, there has been very little published in the English language which would help an engineer in preparing the design for such protective works. Mr. Case has, therefore, in the little book which is before us, filled a gap in English technical literature.

The book is exceedingly well written, and should be quite interesting to any engineer, even though he has not in prospect the construction of shore-protection work. It describes in some detail the nature of sand dunes and formations throughout the world, explains the movement and the forces behind the movement of the sand, and outlines somewhat extensively the damage which can be done by the sand movement. The latter part of the book is devoted to the various methods of protection which have been utilized in different specific cases. While quite a good deal of the book is devoted to the groin construction, far more is concerned with the planting of trees and bushes.

⌘

THE PANAMA CANAL—By Frederic J. Haskin, author of "The American Government," etc. Garden City and New York: Doubleday, Page & Co. Cloth; 5x8 in.; pp. x + 386; illustrated. $1.35, net.

This is one of the many popular books on the Panama Canal which has appeared recently. The author is a well known newspaper correspondent and is able to write in a very entertaining manner. The book is based on facts taken from the official Panama Canal *Record* and illustrated by reproductions of official photographs, and therefore, so far as engineering data go, is accurate; indeed, the chapters on engineering features have Col. Goethals' endorsement.

It is a book intended for laymen and not for engineers, and is written in the breezy newspaper style of superlatives, with which all are familiar. It is unfortunate for the fame of other continents that the same public [illegible] [illegible] cannot be presented for great engineering projects [illegible].

⌘

CHEMISTRY IN AMERICA: Chapters From the History of the Science in the United States—By Edgar F. Smith, [illegible] Professor of Chemistry, University of Pennsylvania. New York and London: D. Appleton & Co. Cloth; 5x8 in.; pp. viii + 356; illustrated. $[illegible], net.

Before the author became Provost of the University of Pennsylvania, he was in great demand for remarks on

the development of chemistry and for lectures in the classroom and out of it. Much more from the original sources of Prof. Smith's various addresses have been presented in this printed form than could be given in the limits of any set of lectures. He quotes some papers left by a few men of investigative nature in colonial days and outlines the activities of the Philadelphia Chemical Society (1792). Certain eminent pioneers are the subject of biographical sketches—informally and with regard to their works rather than their lives. Among these, memoirs of James Woodhouse, Thomas Cooper, John Maclean, Robert Hare and Benjamin Silliman, occupy considerable space and a score of others are crowded into smaller compass.

Thought and Method in Administration

Reviewed by Edwin R. Douglas*

BUSINESS ADMINISTRATION; Its Models in War, Statecraft and Science—By Edw. D. Jones. New York: The Engineering Magazine Co. [Works Management Library.] Cloth; 5x8 in.; pp. vii+275. $2, net.

The argument for this book is given in its first chapter. Considering briefly the industrial history of the United States during the times of the pioneers and of the development of mechanism, the author passes to the present beginning of the age of administration. Regarding this he comments substantially as follows:

The executives who first took advantage of conditions were self-made men, captains of industry. Their era has been marked by a lack of clear distinction between the process of amassing a fortune and the requirements of administration.

There is now being introduced into industry the judgment of the action itself, regardless of the personal reward which may have been received. "Scientific Management," which took its rise as a philosophy of the shop, has culminated in a group of principles constituting an earnest of a forthcoming science of administration. There is being created a central strategic position to be occupied by the professional administrator.

A new and larger conception of industrial leadership is called for. Society is no longer satisfied to trust, for its administrators, to processes of "learning through experience." What is wanted is a body of principles of industrial action.

The remainder of the book is devoted to a study of those general principles of administration revealed in military and political history, science and diplomacy. The records are full of achievements in these fields and to them we are confined, for the Captains of Industry have been too much occupied to formulate and record the principles by which they acted.

Under the headings, "The Administrator as General—as Scientist—as Diplomat," these three branches of human effort are studied in turn, historically and analytically. The principles discovered are, by analogy, applied to business administration. As stated, they range from Decision, Initiative, Preliminary Planning, through Economy of Means, Openmindedness, Fertility of New Viewpoint, to Courtesy, Compromise, Just Proportion; about two dozen altogether.

Opinions may differ as to a list like this, particularly as a statement of principles; there will be little question as to the unity of the underlying principles in all forms of administrative effort. A chief merit of the book is in bringing this fact prominently to the mind, and in emphasizing the importance, to the coming Business Administrator, to his business, and to society, which he will serve, of a broad foundation in generalship, scientific method and diplomacy. The book is an exposition of Thought and Method in administration.

*Mechanical and Electrical Engineer, Philadelphia, Penn.

REGULATION OF PUBLIC SERVICE COMPANIES IN GREAT BRITAIN, With Supplemental Chapters on the Boston Sliding Scale and Toronto Auction Sale and Maximum Dividend Plans—By Robert H. Whitten, Librarian-Statistician, Public Service Commission for the First District, State of New York (154 Nassau St., New York City). [Reprint of Appendix G, Annual Report of the Commission for 1913.] Paper; 6x9 in.; pp. 231.

Mr. Whitten recently completed for the National Civic Federation a six-months' study of the regulation exercised in Great Britain over public utilities. The material gathered forms the basis of a lengthy dissertation, a readable "story" virtually, which the Public Service Commission for the First District of New York (with which Mr. Whitten was connected) has printed as an appendix to its 1913 report.

While the report is a study of regulation as a whole—as affecting organization, rights, capitalization, vested interests, voting powers, operation, accounting, dividends, etc.—the greatest interest centers on some aspects of British regulation greatly at variance with our own practice—lack of general regulatory acts and the number of special bills, sale of new stock by auction and tender, retrogressive scales of voting power, outside audits, dividing scales to govern rates and dividends. A large part of the volume is taken up with the last topic. British acts embodying it are reprinted and such information as is available on the practical operation. With this is also a review of the arguments on both sides of the water as to the proportion of division of excess profits.

MODERN CITIES; Progress of the Awakening for Their Betterment Here and in Europe—By Horatio M. Pollock and William S. Morgan. New York and London: Funk & Wagnalls Co. Cloth, 5x8 in.; pp. x+418; illustrated. $1.50, net.

The authors have brought together in a series of chapters on such topics as city planning, city streets, art in cities, parks, harbors, government and education a considerable amount of readable information relating to what they term "social progress and civic betterment" and "the best modern features and ideals of American life." Frequent reference to conditions and achievements in foreign cities are based largely on an extensive European tour made in 1910. The book contains some useful facts and statistics but these appear to have been chosen to enforce the argument for municipal betterment rather than to be of direct practical use in bringing it about—which is not a fault in a book which is primarily inspirational in character.

A report on the "Fourth General Adjustment of the Precise Level Net in the United States and the Resulting Standard Elevations," by William Bowie, Inspector of Geodetic Work and Chief of the Computing Division, and H. G. Avers, Computer, U. S. Coast and Geodetic Survey, has just been issued. This is the authority on precise spirit leveling and should be included in the library of every engineer interested in this branch of engineering. Besides a description of the instruments, methods of fieldwork, computation, etc., the report contains

a revised list of precise-level benchmarks, with their descriptions and adjusted elevations, all through the United States. The advantages of tying local survey nets into the national precise-level net is not fully appreciated by many engineers and surveyors; yet it is the only way in which a city datum may be settled once and for all.

A Public-Health Compendium

PREVENTIVE MEDICINE AND HYGIENE—By Milton J. Rosenau, Professor of Preventive Medicine and Hygiene, Harvard University; formerly Director of the Hygienic Laboratory, U. S. Public Health Service. New York and London: D. Appleton & Co. Cloth; 6x9 in.; pp. xxviii + 1074; 177 text illustrations. $6.

The modern spirit of health-protective work is reflected in both the title of this admirable book and in the order of presentation of its two grand divisions. That is to say, the author first takes up the prevention of specific diseases, particularly those which are communicable. This done he considers environment in relation to health and disease. The author presents his vast mass of information in the illuminating and discriminating light of long and varied experience in the Federal health service, both field and laboratory, and in the university classroom. The facts so compiled and presented, the author states, "have been collected for the convenience of the student of medicine and the physician, as well as those engaged in sanitary engineering or public-health work."

That the task which the author set for himself was a large one, demanding unflagging industry and keen judgment through many months is evident from the program just outlined and still more evident from the book itself. The latter part of the foregoing statement will be better appreciated after giving a brief summary of the contents of the volume.

First of all, the various communicable diseases are considered separately, grouped according to modes of transference from person to person, as by alvine discharges, nose and mouth discharges and insects. Besides modes of transmission, resistance, immunity, prevention and general considerations are all taken up for the more important diseases.

Following the section on communicable diseases, which fills 396 pages, 121 pages are devoted to immunity, heredity and eugenics; 111 to foods, including milk and its sanitary control; 48 to air, which embraces sewer air and ventilation and heating; 27 pages to soil and its relation to disease; 117 to water, including conservation, sources, analysis, purification and relation to disease; 26 to a rational treatment of sewage disposal and 4 to refuse disposal, both by Prof. Geo. C. Whipple; 35 to the very important subject of vital statistics, by Dr. Cressy L. Wilbur; 78 to industrial hygiene and diseases of occupation; [illegible] to schools; and, finally, the book closes fittingly with [illegible] pages on [illegible].

The very fact that Dr. Rosenau's book is the most recent comprehensive survey of the whole field of public health goes far toward placing it ahead of anything else on the subject in the English language. Add to this that the plan of the book is better suited than the older ones to the needs of the day, and that the plan has been well executed, and the leading position of the book is assured.

Although the statements in the foregoing paragraph are made unqualifiedly—in fact, with pleasure—we cannot refrain from suggesting that a smaller book might be more serviceable and that this and other huge treatises on public health might be made shorter by one or both of two methods: (1) By not repeating so much already in print in a score or several score books, and (2) by not trying to make one and the same volume serve the physician and the engineer. We are well aware that the classroom lecturer and the textbook writer must repeat many oft-told tales and that there is a considerable demand for what may be termed the single encyclopedic volume. If the engineer and doctor, in embryo or in practice, are to be served by a single book, would it not be better to treat each branch of the subject with relative brevity, dealing chiefly with principles and referring to existing works for most of the detail?

As an illustration of the briefer treatment, Prof. Whipple's four pages on refuse disposal may be cited. In those pages he tells all that most doctors need to be told on this subject and enough to serve many engineering students. The engineer who wants much more information might better go to some of the books cited at the end of the chapter—although the most recent book is omitted; an unfortunate omission, because it is a British book and the British lead the world in refuse destructors.

Another pertinent question is whether in this or any other book of as wide a range, collaboration should not be practised to a larger extent than was done in the present case, thus lessening the time required to prepare the book and making it more uptodate when published, besides lessening the volume of matter that is sheer compilation and giving more from the pens of specialists in the subjects treated.

Such questions as we have raised are not designed to belittle the value of Dr. Rosenau's monumental work. If he set himself a higher task than some may think to have been necessary, no one can deny that he planned and executed it most admirably and that he deserves high credit both for the magnitude and character of his accomplishment.

HEAT—Prepared in the Extension Division of the University of Wisconsin by E. M. Shealy, Assistant Professor of Steam Engineering, University of Wisconsin. (Engineering Education Series.) New York and London: McGraw-Hill Book Co. Cloth; 6x9 in.; pp. vi + 262; 119 text illustrations. $2, net.

In connection with the extension teaching of the University of Wisconsin, a series of elementary texts of unique merit is being built up, and this addition to the list maintains the degree of excellence attained by earlier volumes. Prof. Shealy has given here an exposition of heat phenomena and their common application, for men in mechanical pursuits but of limited education in physics particularly. Such a treatise should also be of service to a great many engineers who years ago have forgotten the details of the physics of energy reactions, on account of their mental preoccupation in construction.

The first part covers temperature effects and measurements. A following chapter distinguishes between force and work and describes an elementary steam engine. Then energy and power are differentiated. From here on, heat phenomena are directly involved—generation, transference, development of pressure in gases, effect of compression and expansion, properties of vapors. This completes what might be called Part One, though there is no such formal division. From here on, machinery and commercial processes are described. The steam engine is described in further detail; air compressors and explosion engines are briefly passed over. Chapters on modern refrigeration and house heating close the work.

British Utility Management

THE MANAGEMENT OF PUBLIC ELECTRIC SUPPLY UNDERTAKINGS—By A. Hugh Seabrook, General Manager, St. Marylebone Electric Supply; formerly Engineer and Manager, and subsequently Consulting Engineer, West Ham Electric Supply. London: "The Electrical Times," Ltd. Cloth; 6x10 in.; pp. 192. 7½ shillings, net.

Mr. Seabrook is a British utility engineer and his dissertations in this volume were intended for British managers, who labor under conditions quite different from our own. But what is said of English utilities as they are and as they might better be, is, nevertheless, of interest to American managers. Moreover, not all conditions are so unique in the British Isles that we cannot profitably study the utilities there.

The book is based on lectures to technical students but it is of greatest interest to men active in the industry. The earlier parts of the book are very general—Chapter I pleads for better public relations and Chapters II and III discuss the burning questions of industrial employment. After about a fifth of the book is passed through for such matters, the writer confines himself more to the electricity-supply field.

First, the advantages of electric service are pointed out alluringly "to emphasize the importance of good and efficient management." The author argues that the best service comes from private companies under municipal regulation.

The organization of an undertaking with a plant of about 20,000 kw. capacity is described—embodying the author's ideas of a general manager and chief engineer (one person) under a "board of management" and over a secretary-accountant, generating engineer, mains engineer and sales manager, each with a complete staff. Yet in discussing organization, the author seems to admit that these four colleague deputies must be a wholly sympathetic quartette filled with the spirit of coöperation or else the big boss of all must never fall ill or go away. The scheme will be criticized on both sides of the pond by those who have achieved success with say two deputies and an automatic succession down the line to the mantle of authority in the absence or illness of those higher up.

The main office for this undertaking is described in detail—if this were more than a dream, employment with this concern would be most alluring. It is on the main street; there are revolving doors and a "smartly uniformed commissionaire" selected for marvelous politeness and intelligence. There is a "spacious waiting room comfortably but not luxuriously furnished"; a few daily newspapers and reference books are to be seen there, and, in the background, catalogs and advertising literature. There are consultation rooms and show rooms—and everything worked by electricity. All this for the 20,000-kw. concern!

The ideal General Manager is described as a man of most wonderful make-up—naturally humane, patient, tactful, polite, forceful, inspiring, fair, receptive, well educated, quick of perception and decision and, last but not least, thoroughly trained in engineering and versed in law and finance. We are warned that unless the man is both a commercialist and an engineer he will fail. We wonder what salary would attract such an intellectual giant to the 20,000-kw. company.

Some 40% of the volume following, sets forth in much detail the organization and working of the four deputies' departments. Here is a fine place for some of our organization and efficiency experts to seek work if British plants really are run this way; for instance weekly statements of detailed costs (of dubious utility) are compiled and there is a monthly analysis of connections and disconnections even down to every fan, cooker and curling iron. There are some technical matters of peculiarity, like the preference for "drawn in" underground mains (even though there may be frequent customer connections), single-conductor in place of concentric-conductor cables, and elevated connection posts wherever possible. Yet most of the discussions awaken an approving response.

The last forty pages are devoted to rates (or, as our cousins more properly call them, "tariffs"). No one will dispute the author's proposition that the object of a tariff system is (1) to secure an income to cover operating and fixed charges and profit; (2) to encourage increased use of electricity for all purposes and by all persons; (3) to avoid discriminations. There is one stated prime object, however, which may or may not be accepted, depending on its interpretation—this is the securing of a "proportional amount of profit from each class of consumer" (though not from each ultimate customer). The author's basis for his tariffs is not cost plus reasonable profit or fair return on fair value but is instead "the value of the service to the consumer which is settled by the price of competitors" (meaning gas or oil, etc.). Fundamentally then the author cannot be in harmony with American rates. This conflict does not extend to the superstructure of rates, as when it is stated: (1) "in calculating charges for a class of new business it is permissible to ignore much of the existing expenditure" with benefit to the original customers due to general decrease in cost of production with the great volume of new business and use of more modern machinery; (2) "it is not necessary that each section of the business should contribute the whole of its share of fixed charges."

The author has a high opinion of the two-part scheme of charging (*a*—a service charge per kilowatt of maximum demand; *b*—an energy charge per kilowatt-hour used) and he has an unique contempt for a single-part scheme. This distrust will not be shared in this country where, by classification of customers and experience with various maximum demands, it has been possible to draw up very simple rate schedules apparently on a one-part scheme but really securing the fair allocation of costs upon a two- or three-part basis.

The author's scrutiny of rate situations has not reached its ultimate stage since he seems to hold that any other utility, like water-supply, must, for equity, make use of a "readiness-to-serve" charge by which fixed charges are distributed according to participation in peak of demand. He neglects the effect of easy storage for such utilities, like water-works, as handle a product and have their investment fixed by total quantity supplied rather than by maximum demand.

※

A comparison of the union scale of wages and hours of labor prevailing in various cities on May 15, 1912 and 1913, is given in "Wages and Hours of Labor Series," No. 7, recently issued by the U. S. Bureau of Labor Statistics, Washington, D. C. The figures are given not only by trades, but also by classes of workmen under each trade.

ENGINEERING MANUAL OF THE AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, Covering Its Standards, Recommendations and Miscellaneous Methods and Practices. New York City: Office of the Secretary, [illegible] Loose-leaf form, [illegible] cloth [illegible]

This manual of the American Electric Railway Association is a compilation of [illegible] standards and recommendations regarding materials and methods. [illegible] the whole electric railway field is covered—buildings and structures, power-distribution lines, poles, rolling stock, signals, track and way, etc. There are 82 sections with [illegible] illustrations; "standards" are on [illegible] paper and "recommended practices" are on white. A loose-leaf binding has been used in hope that members may keep the manual up to date.

REINFORCED CONCRETE RAILWAY STRUCTURES—By J. D. W. Ball, Assoc. M. Inst. C. E. New York: D. Van Nostrand Co. [The Glasgow Text Books. Edited by G. [illegible]] Cloth, 6x9 in.; pp. xiv + [illegible], 127 illustrations. [illegible] net.

This is a British book on which has been placed an American title page. The subject matter is purely British, and applies only in a limited extent to American practice. The author has simplified the formulas for the design of reinforced-concrete members considerably, which is a refreshing novelty in books on reinforced concrete. He evidently recognizes that the peculiarities of construction are so great that extreme refinements in design are not desirable.

Following the usual theoretical chapters, the discussions are on floors, buildings, foundations, retaining-walls, bridges, arch bridges, sleepers (i.e., ties), and fence posts. The chapter on ties is very complete, more nearly so than in any American book.

NEW PUBLICATIONS

(So far as possible the name of each publisher of books or pamphlets listed in these columns is given in each entry. If the book or pamphlet is for sale and the price is known by the editor the price is stated in each entry. Where no price is given it does not necessarily follow that the book or pamphlet can be obtained without cost. Many, but not all, of the pamphlets, however, can be secured without cost, at least by enclosing postage. Persons who are in doubt as to the means to be pursued to obtain copies of the publications listed in these columns should apply for information to the stated publisher, or in case of books or papers privately printed, then to the author or other person indicated in the notice.)

ACOUSTICS OF AUDITORIUMS—By F. R. Watson. Urbana, Ill.: Engineering Experiment Station, University of Illinois. Bulletin [illegible] Paper, 6x9 in.; pp. [illegible], illustrated. [illegible]

AUSTRALIAN COMMONWEALTH STATISTICS—Issued by [illegible] Knibbs, Commonwealth Statistician. Melbourne, Australia. [illegible] Paper, [illegible]

Besides giving what appears to be a carefully prepared plumbing code, this [illegible] contains a brief description and a number of illustrations of the Clarksburg sewer and water purification plants, some useful information for water users and some local [illegible] matter.

SHOP LIGHTING: A Handbook for Superintendents and Contractors. Madison, Wis.: Industrial Commission of Wisconsin. [illegible] J. Watrous. Paper, 6x9 in.; pp. [illegible], illustrated.

SURFACE WATER SUPPLY OF THE UNITED STATES, 1911. Part III, Ohio River Basin—By A. H. Horton, W. E. Hall and H. J. Jackson. Washington, D. C.: U. S. Geological Survey. Water-Supply Paper [illegible]. Paper, 6x9 in.; pp. 11[illegible], illustrated.

Engineering News

VOLUME 72 JULY 23, 1914 NUMBER 4

Large Masonry Arches on a Swiss Mountain Railway

By J. C. Van Langendonck*

In Engineering News, Dec. 25, 1913, p. 1294, there appeared a brief article describing the Swiss railway now under construction from Chur to Arosa and illustrating two of the large concrete arches now under construction. The accompanying cuts show some further views of these handsome bridges and illustrate particularly well the types of falsework used in continental practice.

The meter-gage Chur-Arosa adhesion railway is a branch of the Swiss Federal Railway System. The line, which will be opened for the summer season of 1915, has a length of about 10 mi. It starts at Chur (altitude 1913 ft.), the capital of the Grison Canton, and follows the carriage road along the River Plessur, as far as Sassal, and then ascends along the right side or sunny aspect of the Schanfigg Valley as far as Langwies, where it crosses over the left side of the valley and reaches the terminal station Arosa at an altitude of 5729 ft.

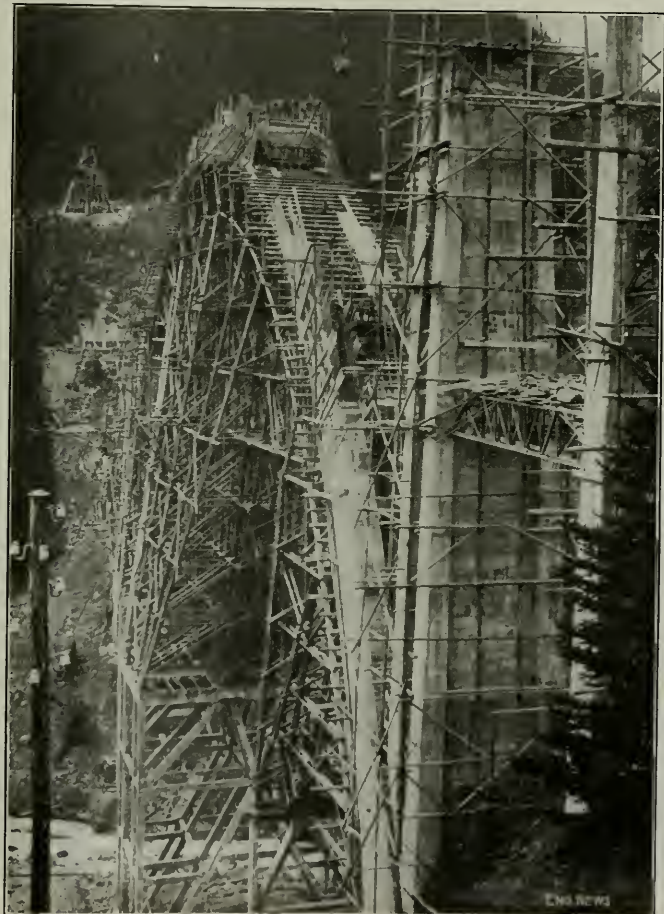

Fig. 1. Centering in Place under the Langwies Arch, Chur-Arosa Ry., Switzerland

The lower portion of the Schanfigg Valley is a wild ravine, and in the upper portion its right slope is furrowed by many deep gorges as far as Langwies, but thence to Arosa fewer constructional difficulties were met. Although the River Plessur is only crossed once—at Langwies—yet there are between Chur and Arosa 27 bridges of stone, three of iron, and two of concrete, as well as 19 tunnels with a total length of 7800 ft.

In the construction of the tunnels, the geological anticipations proved to be correct in every instance, with the exception of the 960-ft. Arosa tunnel, in which clayey moraine-stone and weathered serpentine were met with instead of the gneiss rock which was expected. These much-dreaded moraine formations proved in the wet summer of 1913 to be quite serviceable working ground on which safer foundations were obtainable than, for example, could be got on the detritus declivity below the village of Maladers.

The view on this page shows the famous Langwies Viaduct under construction. As described in Engineering News, Mar. 19, 1914, p. 608, the main arch of this bridge (the second longest masonry arch in the world) has a clear span of 315 ft., and a rise of 140 ft. The viaduct itself is 960

*50 Chaussée de Tervueren, Etterbeek-Brussels, Belgium.

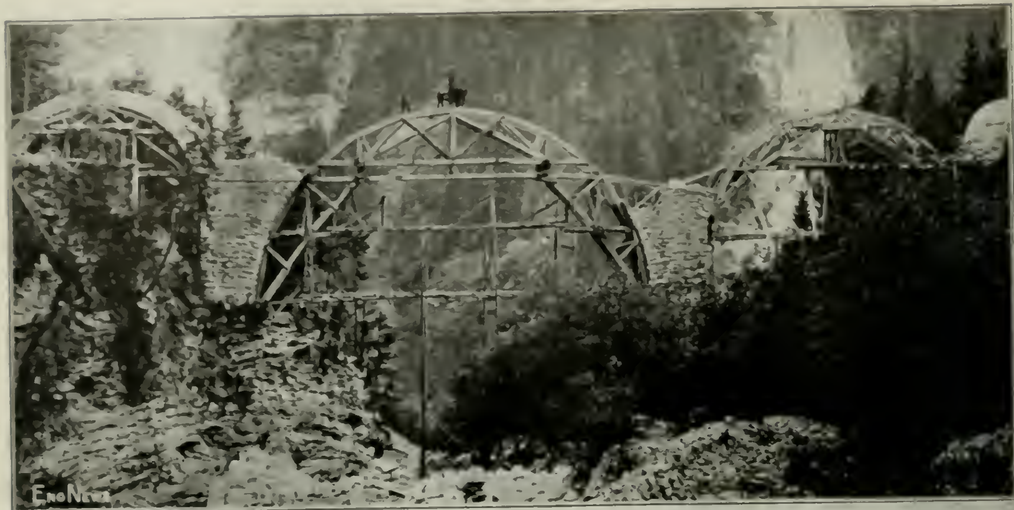

Fig. 2. The Calfreisen Viaduct under Construction, Chur-Arosa Ry., Switzerland
Fig. 3. Building the Castiel Viaduct, Chur-Arosa Ry., Switzerland

ft. long and has a grade elevation of 207 ft. above the valley. The view gives an idea of the very careful construction of the centering for the principal arch, which after laying the green concrete, scarcely showed 0.4 in. deflection.

Another imposing engineering construction on the line is the Calfreisen Viaduct, the centering and piers for which are shown in Fig. 2. Here the two central arches, which have respectively a span of 92 ft. and 60 ft., are built of concrete blocks, while the four lateral arches (40 and

20 ft.) are of tamped concrete. The piers of the principal arch rest on rock, and on account of the scarcity of building stone have a core of tamped concrete cased with quarry stone. In Fig. 3 is illustrated the most imposing stone bridge of the line; it has three arches of 84-ft. span each. The main pier of this Castiel Viaduct has a height of 180 ft. and starts in the middle of the valley.

Superiority of the V-Shaped Flume in Logging*

Of the two types of logging flumes in general use in the United States, the V-shaped has proved more satisfactory, both from cost to construct and efficiency of operation. The square or rectangular flume is the older, and is still used extensively where economy of water is a secondary consideration. Furthermore, owing to its construction, there is a greater chance for leakage in the square type.

It stands to reason that the flume requiring the least amount of material for construction, the least amount of repairs, and in which logs are least liable to jam, is the best flume for general use. Up to the present time, this description fits the V-shaped flume; but it is not unlikely that the portable metal flume already in use on hydroelectric and irrigation projects will eventually supersede the timber flume.

Design and Construction of the V-Shaped Flume

Degree of Angle—Angles of from 70 to 110° have been tried; but the consensus of opinion favors 90°. Future data and references in this article relate to straight right-angle flumes.

Flume or "Boxes"—Construction methods are dependent upon the kind of material to be handled. The sections of the flume or the "boxes" vary in length from 6 to 20 ft. Sometimes only one thickness of board is used, but more often two thicknesses are employed, with joints broken or staggered. The details of the box construction is largely a matter of individual opinion. The aim almost always is to keep down leakage.

A triangular section of wood sawed to fit snugly into the bottom of the V on the inside is sometimes employed for purposes of reducing the amount of water necessary and strengthening the flume itself. The value of this measure is, however, disputed on the ground of too great cost.

Size of Flume—Material to be handled is a prime factor in determining size. For railway crossties, cants, poles, cordwood, etc., a 30-in. (inside width of one side on slant) flume is usually satisfactory wherever there is sufficient water to fill the flume two-thirds full. For the handling of long timbers or "brailed" (clamped) sawed lumber, the size of the V should be from 40 to 60 in., according to the volume of water available and the size of the material to be handled.

Grade—The grade of a flume is a matter to be carefully considered from the standpoint of subsequent operation. An abrupt descent results in rapid wear of the lining, with consequent increase in the maintenance cost and a tendency toward jamming. In the other direction, 1% is held to be the smallest grade for successful operation; 2 to 5% is better. Flumes have been operated for short distances on a 30% grade, but this is undesirable. The most satisfactory is 2 to 10%, and wherever possible below 15%.

Maintaining a steady or even grade necessitates the use of more or less trestling. In order to know just what length of timber should be cut for the bents, it is necessary that a careful survey should have been made. This matter of a careful survey is of importance in more ways than one.

Curves—For obvious reasons a sharp curve is inadvisable. It throws the weight of the material and water to the outside of the curve, with a tendency toward jamming. The degree of curvature should be kept as low as practicable and should rarely be permitted to exceed 20°. Shorter "boxes" and the closer spacing of supporting bents are very necessary in sharp curves.

Cost of Construction—The cost of constructing flumes is, of course, a variable. Rough lumber suitable for construction can ordinarily be cut and fitted at from $7.50 to $10 per M. The cost of construction of the Bear Cañon flume in Montana, a 26-in. V, 10 mi. long, was approximately $2000 per mi. Lumber cost $8.50 per M. to manufacture and fit and about 100,00 ft. b.m. were required per mile. Labor cost $800 per mi., and $350 per mi. was expended for surveying, nails, steel, etc. This flume, however, was constructed a number of years ago, when the cost of material and labor was less than at the present time.

Probably one of the best examples of modern V-shaped log-flume construction is a flume recently constructed on Rochat Creek, near St. Joe, Idaho. This flume, which is unusually large, and strongly constructed for handling large, heavy logs and long timbers, is said to have cost approximately $8000 per mi. for the 5 mi. of its length. This figure includes the cost of constructing a wagon road and of a telephone-line equipment, which latter is a valuable adjunct to flume operation.

*From Bulletin No. 87 of the United States Department of Agriculture; "Flumes and Fluming," by Eugene S. Bruce, expert lumberman. The article discusses the use of flumes in lumbering operations, and tells how to build them, with much valuable data as to the weight of water in different size flumes, velocity of water for different grades in different size flumes, and the amount of material required for their construction.

The Weathering of Coal in the Pittsburgh coal bed where it outcrops on a hillside near Bruceton, Penn., was carefully investigated by the U. S. Bureau of Mines, and the results publisched in a recent bulletin. The data are applicable as a basis for approximate estimates of the alteration of the same bed in other mines similarly situated. It was demonstrated that indications of weathering such as yellowish coatings of iron hydrate or a dull appearance of the surfaces, do not always signify a material change of the chemical composition or heating value of the coal itself. Chemical analyses show that changes in composition have occurred in the coal for a distance of 50 ft. from the outcrop, and that the composition and the heating value of the unweathered coal, computed on the moisture and ash free basis, are fairly constant. An extensive collection of analyses shows that there has been a considerable alteration of the coal substance in the first 40 ft. from the outcrop, decreasing inward. Between 40 and 75 ft., the alternation was slight, and beyond 75 ft. was not perceptible. The alteration manifests itself in a decrease of calorific value (16.3% at 5 ft., 6.6% at 20 ft.), and an increase of oxygen (amounting to 10% at 5 ft.), with a corresponding decrease of carbon and hydrogen. Beyond the zone of weathering (75 ft.), the variation in the largely adventitious constituents, moisture and ash, is not to be regarded as having a relation to the outcrop. The percentage of sulphur in the weathered part of the bed is less than half that of the fresh coal.

Because of the prevailing prejudice against coal having a rusty appearance, and the popular belief that its evaporative power is less than that of fresh looking coal from the same mine, a series of evaporative tests were run on two samples. The results were practically identical.

Building a Granite Shaft 300 Ft. High: The Perry Memorial

An interesting piece of high-class masonry construction is being carried out by contractors J. C. Robinson & Son at Put-in-Bay, Ohio. They are building there the Perry Memorial, a granite monument in the form of a Doric column 300 ft. high, which is to commemorate Commodore Perry's naval victory on Lake Erie in the War of 1812. Work was begun late in 1912, and will be completed this fall. At present the structure has progressed to a height of about 225 ft.

The shaft of the great column is 45 ft. in diameter at the base and 35½ ft. at the throat, just under a square cap 47½ ft. on a side. Its height from top of concrete base to top of cap is 300 ft., but an attic 17 ft. high and a huge bronze lantern 18 ft. high make the total height 335 ft. above base, or about 360 ft. above bottom of foundation. The taper of the shaft is not straight but has the classical entasis, the curve of the side swelling about 4 in. out from the chord. The Doric fluting is a striking feature of the shaft; there are twenty flutes,

FIG. 1. DESIGN FOR PERRY MEMORIAL MONUMENT
(From the architect's preliminary drawing.)

meeting in sharp arrises, from base to echinus just below the cap.

The exterior of the shaft is of Milford (Mass.) granite, backed with concrete to a circular well 27½ ft. in diameter extending the full height of the monument above a ground-floor rotunda. The wall thickness of the shaft thus ranges from a trifle less than 9 ft. to 4 ft., including the granite exterior (18 in. to 30 in.) and a 4-in. brick lining of the well. The lower story is a rotunda, about 77 ft. high, and a trifle less in diameter than the well above; it is roofed with a flat elliptical dome of Bedford (Ind.) limestone backed with concrete. The interior of the rotunda is lined with limestone in decorative panels. Two spiral stairways are formed in the wall around the rotunda, leading to a reinforced concrete floor a few feet above the domed ceiling.

From this floor, a central elevator hoistway 7 ft. square, and a reinforced-concrete staircase surrounding it, extend to the top of the monument. The reinforced-concrete flights are supported by four continuous concrete columns set in a square of about 13 ft., and resting on reinforced-concrete girders between floor and dome. The columns are octagonal, 16 in. on a side, reinforced with eight [illegible]-in. longitudinal rods. There are no floors above the foot of the elevator, the well being open all the way to the top.

An interesting structural feature is the square cap of the shaft which is a reinforced-concrete slab resting on top of the circular shaft. This cap slab has deep reinforced-concrete girders around its outer edge, which form the parapet of a walk way around the attic. The granite facing of the shaft continues along the under side of the cap and the outside of the parapet; the stones here are cut with heavy longitudinal dovetailed keys projecting from their back faces, which will bond into the concrete and so carry the stones. It will be necessary to set this stonework complete (on falsework) before casting the reinforced-concrete slab and girders. The overhang of the cap being about 10 ft. on the diagonals of the square, and the stones of the underside being radial, without transverse joints, large weights will have to be handled and substantial falsework provided for suspending the stonework until the concrete is in and has taken its set.

THE FOUNDATION

The monument is located on a narrow neck of land about midlength of Put-in-Bay Island, where the distance from water to water is less than 500 ft. This neck was a marsh, with rock 10 to 15 ft. below water. Fig. 2 suggests the nature of the site. Both the monument itself and the extensive concrete esplanade which later is to be built around it must be carried to rock foundation.

The monument foundation is ring-shaped. It was constructed between walls of sheet piling driven to rock—except when boulders stopped the sheeting, as the subsequent excavation disclosed. Inflow of water and soft ground, and the necessary removal of boulders, caused much trouble and delay, and the continuous high level of the lake in the spring of 1913 did not improve matters. When rock was finally reached and cleaned off and a little stepping done, the concrete placing was a simple matter, and the ring was soon built up to grade, about 10 ft. above ground. Toward the end of June, 1913, the base was ready for the shaft to be begun. Setting the first ring of stone was hurried, and the formal cornerstone-laying occurred on July 4. Fig. 2 shows the condition of the work a few days earlier.

BUILDING THE SHAFT

The granite facing is laid out in 3½ ft. courses (3 ft. 9 in. near the base). It is set two courses at a time, and the concrete backing for these is then placed before more stone is set. Flat anchor-straps hooked into holes in the beds of the stones tie them back into the concrete, though the grip of the concrete also binds them in efficiently.

Setting the stone is the main operation. The courses of stone are all different (on account of the batter) but have the same bond, as sketched in Fig. 3. By shifting the ring shown in Fig. 3 one flute either way, the bond of the next course is represented, but the next course is deeper, header and stretcher courses alternating. There are only three patterns of block per course, making up a width equal to two flutes, so that there are 30 stones per course. The cutting is all done at the quarry. Joints are cut true for a width of at least 4 in., back of which they recede.

In setting the stone, the sharp arrises between flutes must be plumbed perfectly, and the batter must be set true. For the latter, a cleat or block of proper thickness, nailed to the edge of the plumb-level near one end, enables the batter to be obtained by direct plumbing. The

cleat must be changed at each change of batter (usually every three courses).

Each stone is set with its face true to the stone below at the bed joint, and every two courses the diameter is checked up. Any variation from correct dimensions is noted, and made up in setting the next course.

As a stone is hoisted to place it is lowered onto its mortar bed by the derrick, set true and plumb, while the derrick still holds the strain, and then wedged in position by wooden wedges. After slacking off the derrick, mortar is packed into the back of the bed joint to fill, while the builds are just closed with mortar, leaving the further filling for the concrete.

The back of each stone is painted with R. I. W. to prevent staining. The granite (also of limestone facing in the rotunda) is laid in mortar of white Medusa portland, made near-by in Sandusky. The face joints will be pointed with the same mortar after completion of the masonry.

Concreting back of the facing is done against segmental inner forms. A central concrete hoist dumps its bucket automatically into a hopper bracketed to one side of the hoist tower near its top (several feet above the highest level of wall to be built with that setting of the tower), and from here the concrete is distributed to the wall forms by chutes. The forms are strutted to the tower (sometimes clear across to the opposite wall), and the bond straps of the granite stones are wired inward to the forms.

In a few cases, the pressure of the liquid concrete placed behind the granite pushed out a facing stone. These accidents prove that thorough tying is important.

The concreting is done in heights of but two courses for the reason that the third or header course would create a difficult pocket to fill solid. However, the matter of pressure of concrete would probably also be troublesome at depths greater than two courses or 7 ft.

Handling Material

The lower part of the shaft was set by a yard derrick close by. This is a derrick with 65-ft. wooden mast and 90-ft. steel three-section extension boom, which normally handles the stone in storage around the base of the shaft and serves the concrete mixer plant alongside. Above the reach of this derrick, all work was done from the inside.

The weights of single blocks in the lower section ran up to as much as 5 tons; generally in the shaft the weights were around 2 to 2½ tons, but in the cap some 4- to 4½-ton blocks will have to be handled.

Two stone-setting derricks are stepped at diagonally opposite corners of a timber tower which is built up in the center of the well, around the permanent elevator framing, and this framing is used as the equivalent of derrick masts. Within the elevator frame a self-dumping concrete hoist operates, to a height which may be as much as 70 ft. above the wall when extended for a fresh raise. Only the concrete is taken up in this hoist; stone is hoisted outside by the two stone-setting derricks.

The construction of the derrick tower is sketched in Fig. 9. The steps for the booms are bracketed just above a square ring of 4x14 timbers clamped around the elevator angles. This ring is carried by eight 12x12-in. raking struts set on jack-screws in notches cored in the concrete about 30 ft. below the boom steps. The struts are in the planes of the sides of the elevator frame.

The topping-lift block is hitched to a forged ring fastened to the corner of the elevator frame about 25 ft. above the boom step. Back of this ring are attached two 1-in. wire-rope guys extending about 60 ft. down to an anchorage in the concrete wall of the shaft. There are two guys at each corner of the tower, eight in all; the guys on each face of the tower are crossed, as shown in the sketch, so that in ground plan they are in planes nearly parallel to the diagonals of the tower. The mast stress of the derrick goes down the single 6x6x½-in. elevator angle. Timber strutting and bracing are clamped to the sides of the elevator frame above the boom seat to stiffen the mast angles and form a full-braced tower up to the level of the concrete hoist sheaves. Below the boom seats no bracing is used. There are no permanent diag-

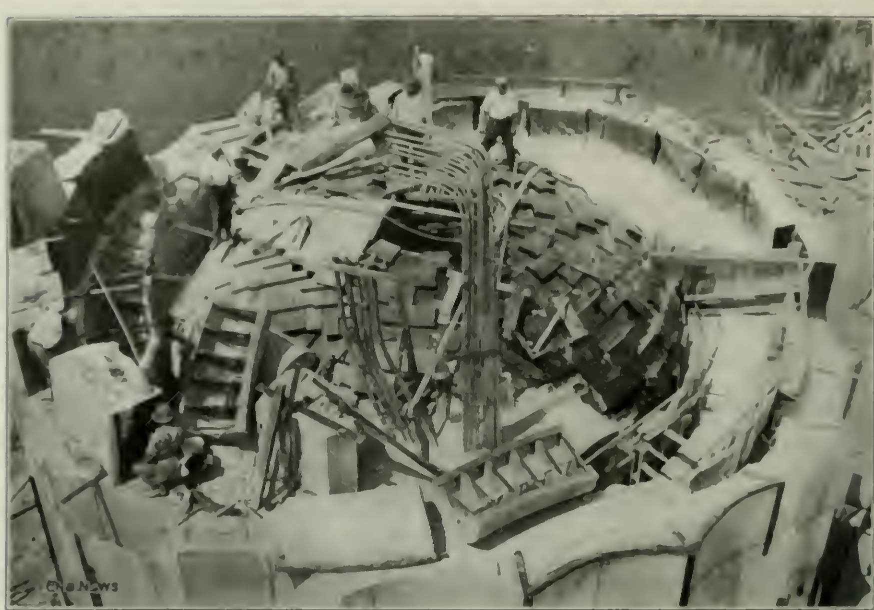

Fig. 5. Elliptical Vaulted Dome of Rotunda in Lower Story of Tower. View of Stone Vaulting before Concreting

onals in the elevator framing, the reinforced-concrete staircase being relied upon to hold it laterally.

In making a new setting of the derricks, the legs for the boom seats are set on top of the finished concrete wall, notches having been cored out here. Anchor stirrups of 1-in. square iron, concreted in two courses (7 ft.) lower down, give points of attachment for the mast guys which run up to the tower. This allows of setting and rigging the two booms complete. As the concrete hoist inside the elevator framing goes above the level of the mast-top, no horizontal diagonals can be put in to secure the square framing against distortion in a diagonal direction.

The load and boom lines are run down the boom to sheaves at the step, and continue down alongside the elevator angles to the floor above the rotunda. Here they

Fig. 6. Construction of Spiral Stairway

Fig. 7. Spiral Stairway after Removal of Forms
(Concrete has been [illegible] for [illegible] with glazed tile lining.)

are turned by two sheaves to pass down just inside the hoistway to the ground, and run out through holes in the foundation wall to the engine house.

One setting of the derricks is counted on for a raise of about 60 ft. of shaft wall. Fig. 9 sketches the extreme positions. With so great a raise, the upper courses of stone interfere with the boom in position for hoisting from the ground, and a gap must be left here, the remaining stones hoisted and set around temporarily inside, and then the gap closed with the boom topped in.

The concrete bins and mixer, alongside the shaft, are supplied by the yard derrick. Concrete is discharged by a chute into the basement of the shaft, whence it goes up by the concrete hoist.

Special Work in the Rotunda

The rotunda involved special work, on account of the limestone side facing, the two spiral stairways in the wall, the dome, and four deep reinforced-concrete girders over the dome which carry the staircase columns above.

The views Fig. 2 and 5 represent the wall construction of the rotunda and the dome work respectively. The

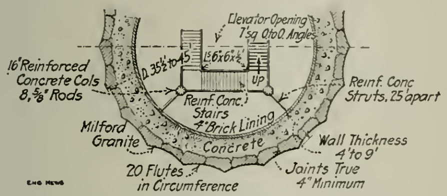

Fig. 8. Sketch of Part Cross-Section of Shaft of Perry Memorial

walls were concreted (in several stages) after setting both granite and limestone and building the forms for the spiral stairways between. The thin stonework of the dome was laid on centering and keyed up, and then backed with concrete; the view indicates the header and stretcher arrangement of the blocks.

Work Inside the Shaft

The brick lining of the shaft, kept far below the wall work, is laid from a ringshaped safety scaffold hung from cross-timbers above. A little lime is mixed with the portland cement in the mortar for the brickwork. Wire loops formed into the concrete wall hold the lining. The brick is buff Kittanning face-brick, practically vitrified, and highly nonabsorptive.

The stairs and their supporting columns are built in stages of about 25 ft., the height of a full turn of four flights. The column reinforcement and the electric-wire conduit inside of it being set, the form is placed and plumbed, and the column then cast to the bottom of the next stair-landing. The depth of column joined to the landing is later cast with the landing, and at the same time a radial strut is cast which here extends from the column out to the wall, bonding into a recess molded in the wall concrete.

The stairs comprise reinforced-concrete stringers on either side, reinforced with rods, and continuous tread and riser construction reinforced with expanded metal. The latter is received in widths just equal to the stair width, and already bent to the required stepped shape in the shop. The sheets drop into place and merely need a few blocks to hold them off the bottom form. Several flights are usually cast at once.

The only standing staging used in the shaft is that required for the column and stairwork. Ladders on side platforms resting on beams thrown across the shaft have

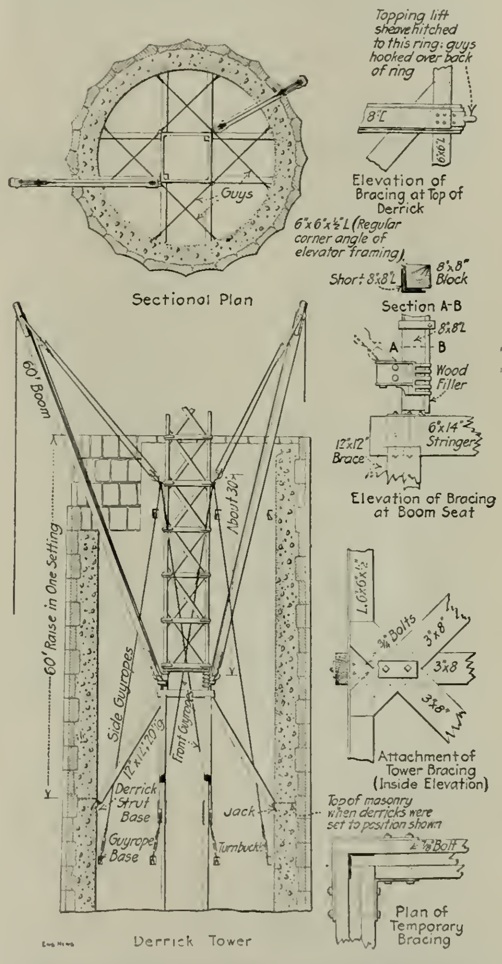

Fig. 9. Erecting Derrick for Perry Memorial

been used for the men up to now, but a temporary passenger hoist is now being installed.

Finish

On completion of the structure, the exterior will have to be cleaned off and pointed up; the sandblast may be used for cleaning. The inside brickwork will also require cleaning of cement stains, etc. The concrete column and stairwork is being rubbed with carborundum brick, holes and voids being first filled with cement.

Reinforced-Concrete Esplanade

The monument itself is to be surrounded by a concrete plaza or esplanade extending from water to water (460

ft.) and about 700 ft. long, in cross shape, covering an area of close to 5 acres. As it is some 10 ft. above present ground level, it is designed as slab-and-beam construction of reinforced concrete resting on piers and walls carried down to rock. The money required for this work is not yet at hand, and the monument will probably stand without the esplanade for a time. The floor of the esplanade will be 4 in. above the base of the granite.

The Perry Memorial Association is building the monument, with subscriptions collected for the purpose; Geo. C. Worthington, Cleveland, Ohio, is President General. Freedlander & Seymour, of New York City, are the architects, and Major Cassius M. Gillette was Consulting Engineer in the earlier stages of the enterprise. Boller, Hodge & Baird designed the structural parts. C. E. Sadler is Engineer of Construction supervising the work. The contract work is in personal charge of B. H. Robinson

Pavement Foundations for Heavy Traffic

By Daniel B. Goodsell*

SYNOPSIS—The author gives the results of an investigation of English experience with portland cement pavement foundations under particularly heavy traffic, especially of motor vehicles. English engineers seem to have come to a conclusion that 6 in. is not a sufficient thickness of concrete to meet present and forthcoming traffic conditions. Concrete foundations for asphalt and wood-block pavements may soon have to be increased from the now almost universal 6-in. depth to 9 or even 12 in. to safely care for the enormous loads put upon them by heavy motor trucks and omnibuses.

The writer has recently had occasion to make inquiry as to whether damage has been done to concrete foundations of city pavements by motor vehicles, and if so the nature and extent of such damage, together with the weight of traffic causing it. The intention was to determine if the present concrete foundations were sufficient and to determine whether occasion exists for increasing the thickness to accommodate the rapidly increasing weight of vehicles.

In order to present an idea of the stresses which may be produced by heavy vehicle units or groups of units, the accompanying Table I, based on observed weights and tire widths, is presented for consideration. It is believed that the weights represent average conditions for trucks in the Borough of Manhattan, New York City. The maximum weights on the axles or tires are not given, and, of course, would be considerably above the average weights shown, which are, in the absence of data, assumed to be evenly distributed on the four wheels.

A coal firm in the borough, in its busy season, has 150 trucks at work, 9 of which weighing 6 tons each carry loads of 10 tons, 11 weighing $3\frac{1}{2}$ tons each carry 6 tons and 50 weighing $2\frac{1}{2}$ tons each carry 7 tons. Loads of from 10 to 15 tons are common.

A search was made of the proceedings of various engineering societies, of periodicals, etc., for expressions of opinion or statement of facts concerning the subject. What was found is here presented. London is apparently the only city where the damage alluded to has occurred, and, although communication was had with a number of officials in the larger cities in the United States, no information was elicited; and it is hoped that some facts may be brought out by this paper.

Extracts from Printed Reports and Papers

DAMAGE TO ROADS, MIDDLESEX, ENGLAND—As to 6 in. of concrete being insufficient on roads, experience bears out that opinion. On the Green Lanes, Wood Green, after six months' motor traffic the wood paving was found to be not only corrugated, but in blisters and depressions and it was necessary to reconstruct the road.

When the wood blocks were removed it was found that the 6-in. concrete foundation underneath was so absolutely fractured that there was not a square yard of sound concrete left. The whole of the material was fractured and damaged to such an extent that it not only had to be excavated but relaid 12 in. in thickness for the wood blocks, which already showed signs of fracture. Cement grouting is never used in connection with wood paving here; a bituminous filler has been found more satisfactory.—H. T. Wakelam, County Engineer of Middlesex, in the "Surveyor," [illegible]

EXPERIENCE IN SHEFFIELD, ENGLAND—[illegible] foundation of cement concrete 6 in. thick, in the proportion of 6 or 8 to 1 [illegible] wood paving [illegible]

[illegible]

The Metropolitan Committee on the Materials and Means of Paving the Streets of London received a number of replies in response to an inquiry whether motor

traffic has had the effect of increasing the cost of paving and maintenance. In most cases the answer is in the affirmative. Many surveyors report that they are finding it necessary to increase the depth of the concrete foundations. In Bermondsey, for instance, while concrete 6 in. deep was formerly sufficient, the depth is now being made 9 in. or even 12 in. In Hackney foundations which were sufficient a few years ago are now found quite inadequate, and in new work the concrete is being made 50% thicker.

The City Surveyor of Hampstead considers that the life of wood paving has undoubtedly been reduced by one or two years, and that it has become necessary to increase the thickness of the concrete foundations from 6 in. to 9 in. In Holborn, concrete foundations 12 in. thick, are being laid in places where a thickness of 6 in. was sufficient ten years ago. In Paddington, concrete from 10 to 13 in. thick is being used on wood-paved carriage ways where the thickness was originally about 7 in. In Westminister the specifications now used when new foundations have to be laid provide for 1 in. of "floating" and 8 in. of concrete foundation instead of 6 in.

FOUNDATIONS OF ASPHALT PAVEMENTS—The thickness of hydraulic concrete necessary will vary under different circumstances. It has usually been 6 in. for sheet-asphalt pavements, carrying the heaviest traffic. At times the thickness is reduced to 4 in. on residence streets. Such a thickness will not be found sufficient to carry the travel which is promised in the future either on such streets or on some of our country highways.

With the advent of the motor truck, the traction engine and the motor omnibus, English engineers have arrived at the conclusion that not less than 9 in. of concrete will be required to furnish a satisfactory support. Such a thickness will be eventually demanded in the United States because in the area included in a radius of 30 miles or more about our own large cities motor trucking is common, with loadings amounting frequently to 10 tons.—"Asphalt Construction," by Clifford Richardson.

EXPERIENCE IN WIMBLETON, ENGLAND—The damaging effect of this latter form of traffic (motor busses), so far as we can see at present, has resulted in the destruction of portland-cement concrete 6 in. thick, where placed beneath wood paving and asphalt.

The author has only found one exception in the London district, viz., that of George St. and High St., Richmond, which carries no fewer than 1155 omnibuses per day of 16 hours, and 1878 on Sundays, equivalent to 55,212 tons per week, on a carriageway 25 ft. in width. The carriageway is paved with 5-in. creosoted deal blocks, laid on a 6-in. portland-cement concrete.

The only reason the author can give for the paving withstanding such a heavy traffic is that it is on a gravel subsoil. In other districts the thickness of the concrete has been increased to 9 in., and where trenches are subsequently made 12 in. is laid as a rule beneath the blocks used in repairing the surface.—Charles Hamlet Cooper, Borough Engineer of Wimbleton, in the "Surveyor," Oct. 10, 1913.

DISCUSSION—In my view, the breaking up of concrete foundations was not caused so much by ordinary motor vehicles as by those over 3½ tons in weight, shod with steel tires, one class of these being allowed to travel at eight miles and the other at five miles an hour. The passage of such vehicles [probably means traction engines with trailers] had the effect of hammering on the road, which did more damage than the twin-tired or any other rubber-tired vehicles (busses or autos)—E. Van Putten, Borough Engineer of Lewisham, London.

REVIEW OF ENGLISH EXPERIENCE—The cost of paved roads was reported to have increased in areas in which the strengthening of foundations had not proceeded very far, but elsewhere this traffic (heavy motor traffic) has not increased the cost of maintenance.

Reports of increased cost of maintenance are usually accompanied by the statement that deeper foundations will be provided in the future. Taking into consideration the increase in the passenger mileage and ton mileage of traffic, the cost of reconstruction and the cost of maintenance, there does not seem to be any cause for alarm as regards the paving of the main routes in the London area.

It is not really necessary, however, to make these foundations of tough concrete throughout, since the greater depth very much reduces the tension on the underside when the foundation acts as a beam or slab, and very greatly increases the area of road bed over which a wheel load is distributed. As a beam a 10-in. slab has 2½ times the strength of a 6-in. slab, and a relatively poor concrete for the lower 4 or 5 in. would in most cases be of ample strength.—Editorial in the "Surveyor," Jan. 30, 1914.

EXPERIENCE IN BELFAST, IRELAND—The concrete bed should be from 6 in. to 9 in. in depth, and vary acording to the subsoil; and having regard to the development of heavy self-propelled traffic, the author is inclined to advise that in no case should the concrete be less than 9 in. deep. —Hector F. Guillan, Superintendent, Works Department, Belfast, in the "Surveyor," July 25, 1913.

CONSENSUS OF ENGLISH RECOMMENDATIONS—The importance of the concrete foundation cannot be over-rated. The foundation should be at least 6 in. in thickness, composed of 1 part of portland cement to 6 of proper aggregate, upon which should be laid a "floating" not less than 1 in. in thickness of 1 part of cement to 2 or 3 of fine granite, slag, or sand, brought up to a perfectly smooth face.—Joint Report of English Engineers, International Road Congress, 1913.

RESULTS OF INQUIRY OF METROPOLITAN PAVING COMMITTEE OF LONDON—Effect of motor traffic on cost of paving and maintaining roads. (Replies by Borough Engineers to queries on above.)

St. Marylebone—The council has increased the depth of concrete foundations for wood paving in the more important thoroughfares from 6 in. to 8 in. and 10 in.

St. Pancras—Many wood-paved streets in this borough have either already been injured or shortly will be by this traffic breaking up concrete foundations insufficient to carry the traffic. The St. Pancras Borough Council have recently had to reconstruct the concrete foundation of Seymour St. when repaving it.

The original concrete foundation was about 6 in. thick, and for many years it proved sufficient to carry the very heavy ordinary traffic of the street, but as soon as two services of motor busses began running, the surface in many places showed indications of subsidence, and on examination the concrete was found to be completely broken up, and it was found necessary at the time of repaving the street to form a new concrete foundation 12 in. thick.

In Great College St. there is a daily and very frequent traffic of a motor steam-wagon, and the condition of the granite pavement in this case indicates the destruction of the foundation.—Tenth Annual Report of Metropolitan Paving Committee, 1911-12.

Experience in the City of Westminster, England—The City Council last year approved an alteration in their specifications for paving work to provide for the laying of 8 in. of concrete foundation and 1 in. of "floating" instead of 6 in. of concrete, and 1 in. of "floating" formerly specified—this, of course, only to apply in cases where new concrete foundation is laid.

Summary

In review, regarding the sufficiency of the present concrete foundations for heavy automobile traffic, a difference of opinion has developed, some authorities stating that a thickness of 6 in., which is now used, is sufficient; and others, notably Clifford Richardson, expressing the opposite view. The writer has been able to collect very few data about the sufficiency of the present concrete foundations in the United States. There does not seem to be enough experience with the destructive action of heavy trucks to warrant a decisive opinion.

There is a very strong consensus of opinion among the English engineers that both foundation and wearing surfaces should be absolutely stable in character; that both the concrete foundation and the asphalt macadam wearing surface or asphalt wearing surface should be so constructed that the aggregate will not move under traffic. Any movement or displacement of the stones in the surface mixtures by the rolling action of heavy traffic

is said to rapidly lead to disintegration of the surface and foundation.

A comparison of the concrete foundations of London, Liverpool and Paris with those of the Borough of Manhattan is difficult to make by reason of the fact that the mixtures used abroad are more lean than those used in this borough. A 1:2½:6 or even a 1:3:8 mixture is common, particularly in Paris. Gravel concrete is very common in both London and Paris.

An inspection of the concrete foundation of the former pavement of Fifth Ave., Manhattan, which had been down for nearly 15 years, except where removed for openings or other purposes, disclosed the fact that there were many wide cracks and deep depressions due to the subsidence of the soil beneath, which in turn was due to shrinkage of fill; and that the bad condition of the foundation was due almost entirely to such cause, and not to wear.

With such a rapidly growing borough as Manhattan, heavy and dense traffic conditions are likely to continue and no doubt will be such as to warrant an increased thickness of the pavement foundations. If this borough had as thoroughly consolidated subgrade conditions as London, it is doubtful whether there would be need of increase in the thickness of present foundations, in view of the fact that the concrete is much richer, stronger and of a better mixture than that used in either Liverpool, London or Paris.

In the writer's opinion, the concrete foundations for all the different kinds of pavement should be made smooth by "floating" the surface, thereby adding to the strength and accurate contour of the surface, which is desirable for all the different kinds of pavement. This "floating" would require a departure in the treatment of wearing surfaces which would tend to improve them.

Useful New Facts About Materials

News and Results Abstracted from Papers Read before the American Society for Testing Materials

Permeability of Paints: A New Research Test

Prof. A. M. Muckenfuss (New Orleans, La.) has experimented with a new kind of test for paints, designed to show how rapidly water-vapor can pass through a paint film. It is as follows:

The paint is spread on a support of hardened paper, wire cloth, or cement, and this is laid (with gasket) over a pan of water and under a mercury-sealed cover which incloses a weighed dish of calcium chloride. The weight gained by the calcium chloride in 24 hr. is the measure of permeability.

The results obtained with this test so far are a stimulus to further experiments. By applying the test after exposing the paint film to the atmosphere, the effect of weathering was studied somewhat. Artificial weathering was tried, by subjecting the film to regular alternations of warmth and cold, moisture and drying, electric illumination and darkness, etc.; accelerated "weathering" of films were found to result.

Strength of Glue

O. Linder and E. C. Frost report the results of various tests of ordinary glue. They find that in judging of glues the following qualities should be regarded: viscosity of the melted solution, strength of the cold jelly (judged by the fingers), odor, reaction, grease content, liability to foaming, ash, moisture, appearance.

The adhesive strength of 35 samples was tested by gluing a [illegible] block between two [illegible] pieces, pressing together under 100 lb. pressure for 12 hr., and, after another 12 hr., pushing the middle block from between the other two in a testing machine. Reducing the results to lb. per sq.in., by dividing by 4, the results showed strengths from 1100 to 1950 lb. per sq.in. for 1 part dry glue to 3 parts water, and 60 to 70% of this for a 1:5 glue.

Prolonged heating lowers the strength. Glue solutions kept heated to 150° F. for 20 hr. showed a loss of 30% to 45% in strength, when tested as above.

New Testing Appliances

A hydraulic compression machine of 125 tons capacity, with width of 10 in. between posts, was designed by W. H. Weston and built for W. O. Lichtner, for testing concrete. It can test an 8-in. square prism to 3900 lb. per sq.in., and an 8-in. cylinder to 5000 lb. per sq.in. Two gages, 10 tons and 125 tons capacity, are attached. The total cost of the machine was $550. Its outside dimensions are 20x32 in. by 60 in. high, and its weight 3000 lb. ("A Simple Compression Machine for Testing Structural Materials," W. O. Lichtner).

Extensometers and compressometers taking measurements on three gage lines, 120° apart, have been used at the University of California. A. C. Alvarez designed them. The measuring is done by roller dials. ("An Improved Type of Axial Strainometer," A. C. Alvarez.)

The American Locomotive Co. has developed a vibratory testing machine claimed to be more accurate and more adaptable than prior machines for vibratory tests. Tension tests, as well as oscillatory tests and rotating vibratory tests under longitudinal tension can be made with full assurance that the grip on the ends will remain firm. A tension up to 40,000 lb. can be applied to the specimen, and a bar of hard steel 1¼ in. in diameter can be tested in the vibratory test. The axis of the machine is horizontal. The machine was built by Tinius Olsen & Co., Philadelphia, to designs of C. L. Heisler. ("A New Vibratory Testing Machine and Results obtained by its Use," S. V. Hunnings.)

A centrifugal sandblast machine for testing brick, etc., by sand abrasion, was built recently at the Municipal Testing Laboratory, St. Louis, Mo., by Mont Schuyler. The vertical shaft of an electric motor, passing up through a fixed horizontal bedplate, carries two oppositely directed tubular horizontal arms. Above these arms the shaft is hollow and at the top it has a feeding funnel, for feeding sand down through the shaft to the arms, whence it is thrown out by the centrifugal force through

the tubular arms. Test specimens may be set on the bedplate in a circle, the tubular arms just clearing the inside of the circle; a sheet-iron cover incloses the working area, the funnel projecting out at the top.

With a given sand, fed in at a given rate, uniform abrasion results are obtained. Different sands give different rates of abrasion, probably due to influence of size of grain. If the machine is standardized in its details and manner of use, it may prove to be a valuable testing device for clay products. In the case of brick, experiments showed a hyperbolic (decreasing) relation between strength and abrasion loss, and a roughly parabolic (increasing) relation between absorption and abrasion, which indicates that the test has practical value. Possibly this form of test may make the rattler test for paving brick unnecessary; it has great advantages in rapidity, definiteness and noiselessness, over the rattler test. ("A Machine for Testing Clay Products," Mont Schuyler.)

Drill-testing to determine the best speed, etc., may be done on a new machine built by Tinius Olsen & Co., Philadelphia. The feed pressure and the cutting torque at various speeds are measured. Drills $\frac{1}{4}$ to 1 in. diameter can be tested at speeds of 50 to 1000 r.p.m., the low speds taking care of taps and dies. Torque is measured by a pendulum weight as in the Thurston torsion-testing machine. An autographic record of torque is made on a rotating drum. ("An Efficiency Testing Machine for Testing Drills, Taps and Dies," T. Y. Olsen.)

To measure the "friction" of rubber hose or belting, i.e., the resistance of the several plies against unwinding or stripping, J. M. Bierer has made an autographic machine which pulls two grips apart at the standard rate of 1 in. per min., and registers the pull on a steam-indicator cylinder. ("An Autographic Friction Testing Machine for Mechanical Rubber Goods," J. M. Bierer.)

The difficulties and uncertainties of present ways of measuring the viscosity of liquids led Prof. A. E. Flowers to suggest a new type. If a liquid is placed in a tube, the tube inclined a little from the horizontal, and a heavy sphere somewhat smaller than the bore of the tube is allowed to roll down in the tube, the velocity of the ball will depend on the viscosity of the liquid. Thorough review of the subject of viscosity brought Prof. Flowers to the conclusion that an instrument using this principle will be accurate and very adaptable, and subject to only slight corrections for different specific gravities of liquid. A small sample suffices for the test. Tests could be made at high temperatures or under pressure, just as easily as under normal conditions. The ball diameter should be one-half to three-quarters of the bore. ("Viscosity Measurement and a New Viscosimeter," Alan E. Flowers.)

Permanent Magnetism

The amount of permanent magnetism which hard steel will retain, and the tenacity with which it retains it, are profoundly affected by the heat treatment of the steel, as well as by its chemical composition. But different steels are affected differently by heat treatment. Some have their best permanent-magnet quality in the oil-hardened condition, while others (0.60% carbon steel and 5% tungsten steel) are best when water-hardened. Thus, the "magnetic hardness" does not vary in the same way as physical hardness. Drawing the temper, however, reduces both hardness and magnetic permanence. In some steels, pieces of small section have greater permanence than larger pieces, while other steels have the opposite characteristic. These facts are some of the results obtained by J. A. Mathews (Halcomb Steel Co., Syracuse, N. Y.) in a very extensive series of magnetic tests on alloy steels. While these tests are perhaps the most elaborate study ever made of permanent-magnet quality of steels, their chief result up to the present is that no uniformity of behavior is found among different steels, and that no laws or theories covering the phenomena can be deduced before a great amount of further experimenting has been done.

Mathews found the best index of permanent-magnet quality to be the ratio between residual magnetism and coercive force (the reverse magnetizing force required to wipe out the residual magnetism). He proposes this ratio as a new magnetic unit. ("Magnetic Habits of Alloy Steels," J. A. Mathews.)

Hardness Tests of Metals

Tests of various metals for Brinell hardness and scleroscope hardness, made at Watertown Arsenal, have been plotted to show what relation exists between the two kinds of hardness. A straight-line relation was found, but different metals lie on different straight lines (all passing through the origin). Carbon steel, nickel steel and chrome-nickel steel fall on the same line, for which the Brinell number is 6.67 times the Shore scleroscope number. Bronze, cast iron and aluminum have lower ratios of Brinell to Shore number, but the tests do not show clearly what these ratios are; that for cast iron is about 5.3. ("Hardness Tests, Relation between Brinell Ball-test and Scleroscope Readings," J. J. Thomas.)

A Simple Deflection Formula for Reinforced-Concrete Beams

The deflection of a beam may be expressed by the area of its M/EI diagram, and this in turn is, for any given method of support and loading, proportional to the maximum moment. From these facts may be derived the following simple formula for deflection of a reinforced-concrete beam:

$$f = k \frac{l^2}{d} (e_c + e_s)$$

in which

f = deflection;
k = a constant;
l = length of beam;
d = depth of beam, to center of steel;
e_c = unit-deformation in extreme fiber of concrete;
e_s = unit-deformation in extreme fiber of steel.

The constant k, in simply-supported beams, has the following values: For uniform loading, $k = 0.1041$; for center loading, $k = 0.0833$; for third-point loading, $k = 0.1065$. In fixed-end beams the values are: For uniform loading, $k = 0.0313$; for center loading, $k = 0.0416$; for third-point loading, $k = 0.0347$.

The formula has been checked by the results of numerous tests of reinforced-concrete beams. ("Relation be-

tween Deformation and Deflection in Reinforced-Concrete Beams." G. A. Maney.)

Fictitious Yield-Point Obtained for Reinforcing Bars by Testing Turned Sections

In testing deformed bars used for concrete reinforcement, it is permissible (according to most specifications) to make the test on a piece turned down to cylindrical shape. At the St. Louis municipal testing laboratory, it has been found that such tests show a higher yield-point than the true one. The error may be as much as 10%. Not only deformed bars, but also plain bars, showed this liability of error. It is due to the nonuniformity of a rolled bar, the interior being of more fibrous structure than the exterior, as photomicrographs revealed. ("The Use of Turned Sections in Tension Tests of Reinforcing Bars." E. P. Withrow and L. C. Niedner.)

Water Purification Plant, Belfast, Maine

By Robert Spurr Weston*

The works of the Belfast Water Co. have recently been improved by building an additional impounding reservoir on Little River and a 1,000,000-gal. water-purification plant consisting of a coagulating basin, two 500,000-gal. mechanical filter units with Wheeler filter bottoms, a filtered-water basin and a wash-water tank. The filter plant was put in service in January, 1914, and is now supplying about 400,000 gal. a day.

Although the object of this article is to describe the purification plant, a few words may be said regarding Belfast itself, the water-works as a whole and the new dam.

The city of Belfast is situated on the westerly shore of Penobscot Bay, between the cities of Bangor and Rockland. It is the seat of Waldo County and is the market town for a locality devoted to dairying and fishing. There are also shoe, clothing, leatherboard and woodenware factories, besides a shipyard. During recent years, the beauties of the bay and its shores have attracted an increasing number of summer residents.

Dam and Water-Works—The original water-works were designed and built, in 1887, by the firm of Wheeler & Parks, of Boston. They consisted of an impounding reservoir with granite masonry dam and pumps operated by both steam and hydraulic power, discharging through about two miles of 10-in. mains to city and standpipe—against a head of 250 ft.

The dam and pumping station are located on Little River, 1.9 miles south from the center of the town. The storage has been only sufficient to drive pumps by water power for three or four months out of each year. So, during 1913, the storage has been increased by building another dam about three-quarters of a mile up the stream.

This dam was built of concrete masonry. Its crest is 220 ft. long and 30 ft. above the bed of the stream; the spillway is 90 ft. wide. The end portions of the dam are straight with the central or spillway section arched. The dam is 13 ft. thick at the bottom and 4 ft. 3 in. at the flow line of the reservoir. It contains very little reinforcement. It was designed by William Wheeler, Supervising Engineer for the Company, and built by the M. W. Allen Construction Company of Walpole, Mass., under the supervision of G. A. Sampson of the writer's office. It required about 200 cu.yd. of earth and 50 cu.yd. of rock excavation; and contained about 700 cu.yd. of concrete, besides gates, pipes and appurtenances. The total cost, exclusive of engineering, was about $8500.

The water supplied directly from the reservoir to the town, while safe to drink, was objectionable on account of its high color and, at times, its pronounced odor and

turbidity. The character of the water is illustrated by the following typical results of analysis:

Source of sample	Reservoir
Date of collection	June 17, 1912
Odor, cold—20° C.	1—vegetable
Odor, hot—90° C.	4—vegetable
Turbidity—silica standard	15
Color—platinum standard	70
Oxygen consumed	6.82
Nitrogen as: Free ammonia	0.022
Albuminoid ammonia—total	0.124
Suspended	.....
Dissolved	.....
Nitrites	0.000
Nitrates	0.06
Chlorine	2.16
Alkalinity	10.0
Hardness by soap method	20.8
Iron, Fe.	0.45
Residue on evaporation: total	41
Bacteria per c.c.—20° C.	145
Bacteria per c.c.—37.5° C.	62
Bacillus coli	Negative
B. coli—presumptive test	Negative

WATER-PURIFICATION PLANT

In addition to the increased storage, which will improve the water, the company has built a water-purification plant, of 1,000,000 gal. daily capacity, consisting of coagulating basin, two 500,000-gal. filter units with Wheeler filter bottoms, filtered-water basin and wash-water tank.

The plant was designed by the writer and built by John W. Gulliver of Portland, Me.; it cost $16,000, including engineering and changes in the pumping station. John M. Cashman was Resident Engineer for both dam and water-purification plant.

The water requires treatment with sulphate of alumina, and, at times of low alkalinity, with soda, followed by storage in a coagulating basin for at least two hours and filtration through mechanical filters. At this writing, less than twenty parts of sulphate of alumina and 5 parts of soda per million are required.

The plant is located on the bank of the tidal estuary near the pumping station, as shown by the view, Fig. 1, and the plan, Fig. 2. The filters and adjoining coagulating basin are in the form of a circle intersecting a rectangle. Beneath the filters, and supporting them, is a filtered-water basin. Both pump well and coagulating basin rest directly upon and conform to the sloping rock on the bank of the estuary.

The reservoir water is supplied to the coagulating basin by gravity, through a 10-in. pipe terminating in a float valve within the basin. Sulphate of alumina is added to the water as it leaves the reservoir, and soda either as the water enters or leaves the coagulating basin.

COAGULANT SOLUTION TANKS

The devices for applying coagulant consist of four solution tanks and two feed boxes, all of reinforced concrete, and two porcelain sinks connected with the two feed pipes, all as shown by Fig. 3. The sulphate of alumina tanks are each 3.25 x 5 ft. x 5 ft. deep.; the soda tanks are half as large. In the corner of each tank is a solution box with perforated bottom and removable screen. Each tank is provided with air pipes for stirring the solution, the air being supplied by a No. 00 Sturtevant pressure blower driven by a 6-in. Pelton wheel. The waste from the wheel discharges back into the filtered water basin.

The solutions discharge from the tanks into feed boxes provided with ball cocks and glass or brass plates, with 20 orifices drilled in each plate, similar to the devices used at Steelton, Penn., and elsewhere. All working parts coming in contact with sulphate of alumina were made to resist corrosion. The screens and air pipes are of hard rubber, the piping is of phosphor bronze, the ball and orifice plate are of glass and the tanks themselves have been given three coats of a solution of white Japan-wax in turpentine. Brass and galvanized iron were used in contact with the soda solution.

The solutions fed through the orifices fall into the two porcelain sinks connected with their respective feed pipes.

COAGULATING BASIN—This (Fig. 4) is built of reinforced concrete with a concrete and earth cover. It is

of irregular shape and has a capacity equivalent to two hours' flow. The treated water enters through the float valve near the bottom and flows over a funnel-shaped outlet into the 10-in. effluent pipe. The bottom of the coagulating basin slopes to a 10-in. drain; a concrete overflow weir is also provided.

FILTERS AND WHEELER FILTER BOTTOM—The filters (Fig. 5) consist of two 500,000-gal. units, each having an area of 192 sq.ft. The filter sand was obtained from Old Orchard Beach, Maine, and has an effective size of 0.41 mm. and a uniformity coefficient of 1.58. The sand layer is 2.5 ft. deep and rests upon a graded gravel layer, 6 in. thick, supported by the Wheeler filter bottom.

The three gravel layers are of the following sizes and thicknesses:

Layer	Thickness in.	Size
Top	3.0	No. 4 to No. 12 mesh
Middle	1.5	0.5-in. to No. 4 mesh
Bottom	1.5	0.75-in. to 0.5-in. mesh

These very thin layers of gravel were made possible by the Wheeler filter bottom* upon which the gravel rested. This device was invented by William Wheeler† to overcome some of the disadvantages of those filter bottoms which are provided with inverted pyramids or troughs, either filled with a very thick layer of gravel or having the lower layer of gravel held in place by screens.

The Wheeler filter bottom consists of a series of inverted pyramids, spaced 1 ft. c. to c. and containing four 3-in. spheres molded from neat cement. These spheres, arranged according to a definite mathematical principle, take the place of the usual random arrangement of gravel or other supporting and wash-water distributing media.

Above the 3-in. balls and around the sides of each pyramid were placed eight glazed earthenware marbles, each 1.25 in. in diameter, and over the larger central space hand-picked beach pebbles of a diameter of about 1.5 in. The 0.75-in. outlets discharge into channels in the concrete, communicating with the 6-in. effluent pipe.

The filter piping is contained within the pipe gallery between the filters. The effluent pipes discharge into the filtered-water basin through Venturi meters and controllers, the recording devices for which are located on the operating platform above. The effluent valve is provided with a hydraulic piston actuated automatically by

†Consulting Engineer, 14 Beacon St., Boston.

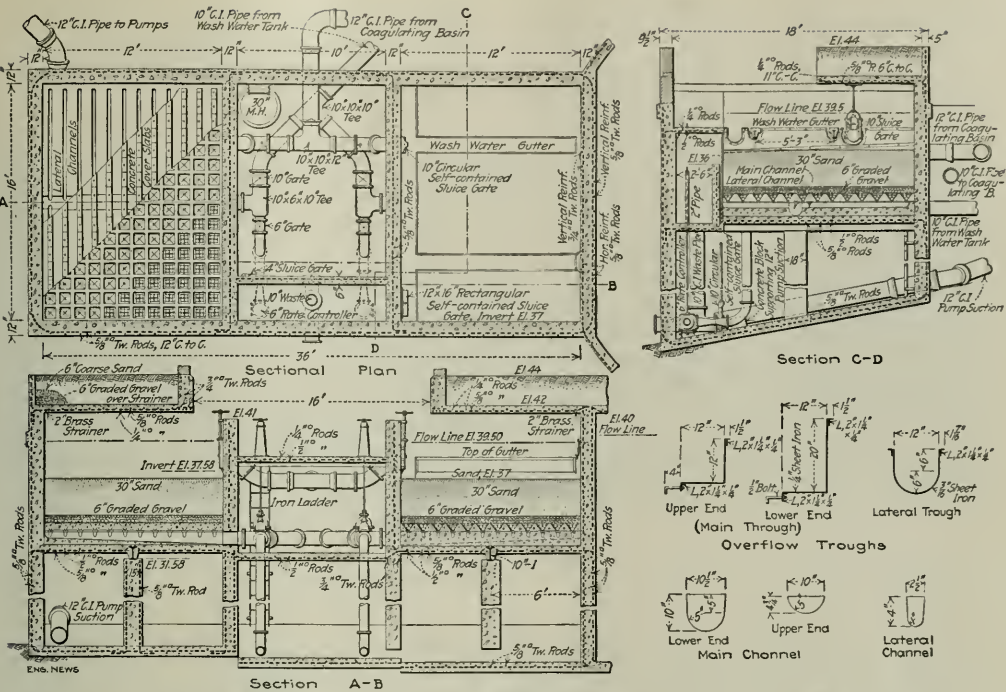

FIG. 5. MECHANICAL FILTERS WITH WHEELER FILTER BOTTOM, BELFAST, ME.

the Venturi devices. The filters are designed to operate without using negative heads.

The wash-water gutters (Fig. 5) are of the usual type. The 8-in. influent gates and the 12x16-in. waste gates communicate with these gutters. The waste gates discharge into a concrete compartment at the end of the pipe gallery. This compartment is connected with a 10-in. waste pipe passing through the pump well, discharging into the estuary; it also serves as an overflow for the filtered-water basin. At the bottom of the filtered-water basin a 10-in. drain connects with the waste pipe.

The 12-in. pump suction connects directly with the filtered-water basin.

The wash-water tank is located on the hill above the filters. It is built of reinforced concrete and is 20 ft. in diameter by 20 ft. deep, with 8-in. walls and a 4-in. cover. The tank is supplied with water from the high-service and a 10-in. wash-water main with 8-in. branches leads to the filters. The tank is provided with a float valve on the inlet and a 4-in. overflow.

Statistics of United States Railways in 1913

The Interstate Commerce Commission has issued an advance abstract of the official statistics of steam railways in the United States for the fiscal year ending June, 1913. This year witnessed by far the greatest volume of passenger and freight traffic that has ever been carried on American railways. The business of the year ending June 30, 1914, has shown a large falling off, as is generally known.

The density of traffic in 1913 is perhaps best shown by the figures for passenger and freight mileage per mile of road. In 1913, 143,067 passengers were carried one mile per mile of road, against 140,393 in 1912. In 1913, 1,245,158 tons of freight were carried one mile per mile of road, as against 1,110,811 tons in the preceding year. A general review of the financial results of operations is of interest, in view of current discussions of the relations of the railways and the public. We omit the details and give the figures in round millions, for the sake of easy comprehension.

In 1913, the railways covered by these statistics (including all roads earning over $100,000 in the year, an aggregate of 244,400 miles of road operated) had total earnings from operation of 3125 million dollars. Of this amount, there was paid out in operating expenses, 2169 million, leaving them 955 million as net earnings. Out of these net earnings the railways had to pay 122 million in taxes, leaving them a net income from operations of 835 million. The railway companies also received from investments in stock of other companies, leased roads, etc., 283 million. They had to pay out in rentals on leased roads, etc., and in interest to holders of bonds and other debts, 630 million, leaving them a net corporate income of 488 million. The money was used first to pay 242 million in dividends to the stockholders who owned this 244,000 miles of railway; $48,000,000 was spent on additions and betterments to the railway property, $50,000,000 on miscellaneous appropriations, and a balance of $184,000,000 was placed to the credit of profit and loss. It will be seen from the above figures that of every dollar which the railways receive in payment for freight and

passenger transportation they paid out 60c. in operating expenses, 4c. in taxes, and 8c. in dividends to stockholders.

The total capitalization of the railways is, in round numbers, 17,800 million dollars. About a third of the outstanding railway stock received no dividends and about 10% of the railway bonds received no interest. The average receipts per passenger per mile in 1913 were 2.08c., and the average receipts per ton-mile were 0.729c. The average passenger train earned $1.35 per mile run; the average freight train, $3.24 per mile run. The average freight train carried 445.25 tons of freight. In 1912, the average was 440.26 tons. Of the total railway earnings, about three dollars came from freight traffic to every dollar from passenger traffic. The total number of employees in the railway service was 1,815,239. The total amount of wages and salaries paid to railway employees was 10,373 million dollars. Thus for every dollar paid out by the railways in operating expenses, 63c. was paid directly to railway employees in salaries or wages.

A Visit to the Lassen Volcano*

By W. H. Wright†

An eruption on Lassen Peak, California, occurring at 10 a.m. Sunday, June 14, had just ceased when I arrived at Prattville, Cal., on the way to Drake's Springs. The mud-cloud still hung over the mountain. A resident of Prattville stated that this had been the largest of all eruptions and earnestly sought to dissuade me from going up to what he seemed to consider certain death.

I visited the peak with two companions on June 16, [illegible] Harry Kaul, who had spent the winter at Drake's Springs as caretaker. Kaul stated that on Thursday night, May 28, he heard a rumbling like that of thunder. Upon going out of doors he found the stars shining brightly. Also that on Friday afternoon, at 2:30, a slight earthquake caused the poorly fastened roof of the barn to slide to the ground. This shock was felt in Westwood, 29 miles, and Susanville, 51 miles, distant. At this time Kaul was probably the nearest to the mountain of any person in that region. On Saturday, May 30, the first eruption occurred, although a stage driver reports seeing a vapor rising from the mountain on Friday. Two days after the eruption, Kaul accompanied a party to the peak. The crater or fissure was then about half its present size, but general conditions were the same. There was not so much debris scattered about, and a small pool occupied a depression in the old crater. Since that time numerous eruptions have taken place, and have all been of the same character. Tin cans left by the party on Kaul's first visit to the peak were picked up by our party. They were badly mashed and dented by falling stones.

Tuesday morning, June 16, our party left Drake's Springs for the summit of Lassen Peak. The trail leads through a magnificent growth of timber. Above 6000 ft. altitude the traveling was done over hard snow, which as we neared the top became very deep. It easily supported the horses and made the ascent much easier than at other seasons. Even close to the peak only a slight amount of dust covered the snow. In Fig. 2 the shadowy area covering the top of the mountain is dust-covered snow and plainly marks the distance any great amount of dust fell. The lighter-colored portions of this area are bare rock covered with cement-colored dust; the dust upon the snow, being wet, is dark colored.

At 12:30 the ridge at the top was gained and our first view of the crater obtained. The party then descended the slope into the cup-shaped depression that marks the site of the ancient crater. The new crater has broken out on the northwest side of this, and seemingly has

Fig. 1. The Eruption of Mt. Lassen

([illegible] June 14, 1914)

†Mining Engineer, [illegible] Bldg., San Francisco.

been formed by steam escaping under high pressure from a fissure which lies along the main axis of the oval-shaped pit. Fig. 3 shows this fissure distinctly. The steam forced its way through the fissure and formed a narrow crater, the sides of which had begun to cave, rapidly widening it.

tain and about a thousand feet from the crater, had its roof perforated in many places by falling rock. The largest hole was 12 in. in diameter and clean-cut.

At the edge of the crater, débris from the different explosions lay on the snow to a depth of three or four feet. This gradually diminished to a depth of 6 in. at the

Fig. 2. Lassen Peak from 8600-Ft. Elevation
(The dark shading shows where the ash fell on snow; the lighter, ash on shale.)

Fig. 3. The Crater
(Track of guide who paced length of crater, at right.)

These pictures were taken at great risk. Aside from the danger of an outbreak of the crater, the danger from the caving sides was great. In order to get good views of the pit it was necessary to go close to the edge. Huge cracks extended back 25 and 30 ft. Every few minutes great masses would fall from the sides. A short time after one of the pictures was obtained, the place from which it was taken suddenly fell into the hole, sending up a cloud of dust and making a spectacular display, which, unfortunately, was over too soon to be photographed, as the party was busily engaged in eating lunch.

The volume of escaping steam varies from moment to moment. In appearance and odor the steam resembles that escaping from the boiling springs which occur along the valley leading up to the peak. That the vapor is steam is evidenced by the fact that it condenses and disappears after rising into the air for a short distance. The hole is about 100 ft. in width and 500 ft. in length. Large quantities of huge rocks have been thrown out. The one in the foreground weighed at least two tons. The deep snow, on the north slope of the south side of the old crater, which was covered with dust, sand and rocks, contained several hundred holes which had been caused by falling rocks. These must have been hot, as they were deep in the snow, which is as hard as ice; also, the sides of the holes are perfectly smooth, and there are many large stones lying on top of the snow beside these holes. Of course, it is possible that the unburied ones did not fall from as great a height as those that are buried. A stone lying 1000 ft. from the crater measured 30x54 in. As it was deeply buried, the thickness could not be measured.

Small heaps of crumbled rock lying on the snow showed that some of the stones crumbled upon being suddenly cooled by it. The lookout station of the forest service, situated on the highest pinnacle of the mountop of the ridge surrounding the cup of the crater. Upon the snow were stones of various sizes. Next is a deposit of coarse sand, upon which is a layer of very fine dust that closely resembles portland cement. There was no lava or cinders. The only indications of heat were the hot stones and steam. The mountain is composed of dacite, which has the appearance of gray granite. If one could collect the débris from a blast in this rock, he would have exactly the same material that has been cast up by the present eruptions.

The edges of the fissure are covered with a yellow deposit that appears to be sulphur. This could not be verified, as it was impossible to reach the fissure. The presence of sulphur is not unexpected, as deposits of sulphur are found at many of the hot springs in this locality. An odor of sulphur was noticed in the dust, but it was so faint that it could not be determined whether it was the hydride or dioxide.

The evidences on the ground bear out the belief that the material thrown out by the outbursts consisted of débris from the walls of the ancient crater broken and forced from the fissure by steam under great pressure. Much of this material fell directly back into the new crater or caved from the side, closing the vent and making other explosions necessary to clear the outlet of the debris.

Lassen Peak is 10,437 ft. high and is the southern terminus of the Cascade range. Like many other mountains in this range, it was thought to be an extinct crater. In the Lassen lava field, which lies to the northeast and north of Lassen Peak, is situated Cinder Cone, the latest active volcano in the United States. History does not record this last eruption, which appears to have occurred in the neighborhood of 200 years ago. This eruption was so quiet that it would not have attracted attention in a sparsely settled country.

Experiments on the Decarbonation of Water to Prevent Lead Poisoning at Lowell, Mass.

About a dozen years ago the city of Lowell, Mass., virtually abandoned a driven-well water-supply of from 2,500,000 to 4,000,000 gal. daily capacity because the excessive amount of carbonic acid in the water corroded lead service pipes and caused lead poisoning among water consumers. Recent experiments* have shown that this water can be decarbonated and rendered noncorrosive by aeration. Although it is not proposed to make the water usable by this means at present, the experiments are worth recording here briefly, as well as the sort of aerating plant which they indicated would best serve the purpose.

Two methods of decarbonation were available: (1) neutralization of the carbonic acid by lime or soda and (2) removal by iron. The latter proved to be preferable since lime treatment increased the hardness and aeration did not.

Observations were made to show the effect of untreated and treated water on three 50-ft. coils of lead pipe: one pipe for untreated water; one for water treated with lime and one for aerated water. Samples were taken after the water had stood in or been passing through the pipe for 4 hr. and for 15 hr.

LIME-TREATMENT—The apparatus for applying lime is described as follows:

The apparatus for the addition of lime consisted of a funnel-shaped saturator 24 in. high and 16 in. in diameter at the top. The lime was slaked in a small receptacle at the side of the saturator and introduced as milk of lime by a pipe which led to the bottom of the funnel. Water was introduced from a perforated nozzle into a pipe which extended vertically through the center of the funnel to the bottom, the supply of water then rising slowly through the milk of lime and overflowing at the top from a circular weir. The capacity of the saturator was such that when treating 5000 gal. per day of water with 1 grain of lime per gal., the time of passage of the lime water through the saturator was about one hour.

The lime water varied in strength more or less but on the average contained 1120 p.p.m. of calcium oxide, or 65.5 grains per gal. of this oxide, these figures being based on determinations of the caustic alkalinity of the lime water as it issued from the saturator.

The flow of lime water was maintained at as nearly a constant quantity as possible, and the amount of raw water was varied when it became necessary to change the quantity of lime added per gallon. The lime water was applied to the raw water without exposing the latter to the air, duplicating, as far as possible, the conditions under which if this method of removing carbonic acid were adopted the lime water would be discharged into the suction pipe of the pumps.

AERATION APPARATUS—This was very simple, comprising 1/8- to 1/4-in. diameter nozzles, throwing a very fine spray, furnished by the Spray Engineering Co., Boston. Nozzle pressures were obtained by a gage, or, in the case of very light pressures, by a manometer tube.

CHARACTER OF THE RAW WATER—Analyses of the raw water made in September and October, 1911, showed the following averages, expressed in parts per million: Alkalinity, [illegible]; total hardness, [illegible]; [illegible], [illegible]; iron, [illegible]; carbonic acid, [illegible]. For the same period the dissolved oxygen, in percentage of saturation, was [illegible].

RESULTS OF LIME TREATMENT—The standard of results with either method of treatment was taken as a maximum lead content of 0.5. Untreated water standing 4 hr. in the lead pipe took up an average of 0.5 p.p.m. and standing for 15 hr., 6.7 p.p.m., or from 10 to 13 times the safe limit.

It had been hoped that a fraction of a grain of lime per gallon would make the supply safe, but it was found that with approximately 1 grain per gal. (100% of lime available) the water still took up 1.5 grains of lead per gal. after 4 hr. and 3.1 after 15 hr., or 3 and six times the safe limit. With 1 3/4 grains of lime per gal., the carbonic acid was practically neutralized and the lead content of the water after standing in the lead pipe either 4 or 15 hr. was approximately 0.5 grain per gal. It was finally concluded that 1.5 grains of lime per gal. would render the water safe, since the 15-hr. test was probably more severe than conditions in practice. Even this result was disappointing, for 1.5 grains per gal. of lime would add 45.6 p.p.m. of hardness. This would increase the total hardness by 80%, bringing it up to about 100 p.p.m., "an amount too great to be satisfactory to consumers accustomed to soft New England waters." Table I gives analyses of untreated water after standing four hours in lead pipe.

p.p.m. = parts per million

RESULTS WITH AERATION—Dismissing lime treatment as "undesirable and uneconomical," the report next discusses the results with aeration. These indicate that aeration by fine-spray nozzles "is very effective in the removal of carbonic acid, although the time during which the spray is in the air is short." The tests also indicated that with a 5-lb. nozzle pressure "the carbonic acid can be reduced from 45 p.p.m. in the raw water to about 3.3 p.p.m. in the aerated water, and that with this reduction, the effect of the water on lead pipes is so far lessened as to render the supply safe."

Table II gives analyses of aerated water which had stood 4 hr. and 15 hr. in lead pipe.

*This article is based on a report on "Improvement of the Water Supply of the City of Lowell, Mass.," made in June, 1914, by [illegible], Consulting Engineer, Boston, Mass. [illegible] is Commissioner of Water [illegible] and [illegible] is Superintendent of Water Works, Lowell, Mass.

The report sums up the decarbonation studies and gives an estimate for an aërating plant as follows:

The removal of carbonic acid by aëration has a great advantage over the lime treatment in that it does not increase the hardness, and further, as indicated by the tests, aëration is more effective than the lime treatment in reducing the corrosive action when an equal amount of carbonic acid is left in the treated water. This result is not what might be expected, because by aëration the dissolved oxygen, which has generally been considered a contributary factor in corrosion, is increased, but the experiments clearly indicate that, with an equal content of carbonic acid, the aërated water takes up less lead than the lime-treated water.

An aërating plant, if constructed, would include a pipe system into which the necessary number of nozzles would be tapped, a concrete pool, and below the pool, a small storage basin with a capacity of perhaps one hour's run of the pumps. The water, as drawn from the wells, would be forced through the aërator, and after falling into the storage well, would be repumped into the distribution system.

It is estimated that the first cost of an aërator, storage well and new steam turbine centrifugal pumping unit of 4,000,000 gal. daily capacity will be approximately $25,000. Assuming that the installation of the aërator will involve an additional lift of 30 ft., the cost of aërating the water will not exceed $225 per 1,000,000 gal., including interest, depreciation and the cost of extra pumping necessitated by aëration. This cost is less than the cost to consumers for additional soap, which would necessarily be used if the carbonic acid were neutralized by lime treatment, and it therefore follows that aëration is the more economical method.

Water from the Cook wells, as this group of wells is called, could be used for summer-peak consumption to supplement the Boulevard-well supply, which Lowell now proposes to treat by (1) coke prefilter operated as a contact bed; (2) sedimentation; and (3) sand filtration for iron- and manganese-removal, as outlined in our issue of July 9, 1914.

Oscillating Signals for Grade Crossings

The demand for greater protection to road traffic at railway grade crossings has led to the designs of signals with special features to compel attention. Such signals are specially desirable where there is much automobile traffic, as the cars approach at high speed and a sign or gate (or even a flag) may not be very conspicuous, while the noise of the engine may prevent the driver from hearing the sound of a train, whistle or ordinary crossing bell.

A crossing signal of this kind which was developed in California and has been applied extensively on steam and electric roads, combines sound, movement and light as means of attracting the attention of highway traffic when a train is approaching the crossing. The accompanying cut shows two of these signals installed recently at the 7th Ave. crossing of the Chicago Great Western Ry., at Maywood, Ill. The steel post is surmounted by a fixed bell of the locomotive type and carries a bracket arm from which is hung a 2-ft. disk having a pendulum movement imparted by mechanism contained in the box at the end of the fixed arm. The disk is swung through an arc of about 3 ft. in length, and makes 40 to 60 strokes per minute.

The disk is hollow, made of two conical plates, enameled red on the outside and white inside (as a reflector), and having a red signal lens in the center of each side. The disk is lettered on each side "Danger, Stop," the former word being in white, while the latter is formed in 6-in. letters of white glass "jewels." In the hollow disk are placed two incandescent lamps (so that if one burns out the light feature of the signal will still be operative); These illuminate the red lens and the word "stop." With the brilliant lights, the swing of the disk, and the sound of the bell, the signal is made very conspicuous, and attracts attention at a considerable distance.

The disk-swinging mechanism and the lights are operated from the electric-light mains, while the bell is operated from a local battery. The bell mechanism and the lights are operated (independently) from the track-control instrument, which is placed 2000 to 3000 ft. from the crossing and is operated by the train. Thus a defect in any one of the three means of warning does not affect the others. The signal can be operated on alternating or direct current and on voltages of 8 to 12 or as high as 110 to 550 volts. The disk mechanism may be operated from storage batteries, lighting circuits or trolley circuit. On steam railways, the rails for the desired distance are charged with current from a battery, the train completing the circuit and operating a relay which connects the motor with the power circuit. On electric railways, the connection to the motor may be made through

Grade-Crossing Signal with an Illuminated Swinging Disk and a Locomotive Bell

a contactor on the trolley-wire or third rail, and operated by the car, while a second contactor serves to break the connection.

The signal was designed to serve as an automatic flagman. In the original form the mechanism and a gong were mounted on top of the post, with the disk on a rod extending vertically above it. But by putting the disk on a bracket at the side, it is made more conspicuous to drivers in the street or road. About 1700 of these signals are in use. The signal has been developed in its present form by the Railroad Supply Co., of Chicago.

Two other forms of swinging or "wig-wag" crossing signals are in use, but to a more limited extent. One of these has a pendulum disk (with central lens and inclosed lamp) hung from an arm of the post, while the post also carries a loud gong or bell. This is a specialty of the Bryant Zinc Co., of Chicago. In the third signal, the post is surmounted by a swinging bell, the shaft of which carries two small red swinging blades; these have a limited travel and are for the day indication only. At night, a lamp mounted in a hood above the bell gives a flashing red light while the bell is ringing, and there may be a crossarm with "Danger" in flashing red letters. This signal, which is made by the Hoeschen Mfg. Co., of Omaha, Neb., has no battery. It has metallic circuits to

magnetic generators placed at the desired distance and operated by the deflection of the rails under passing wheels. The signals may have an electric lamp or a long-burning oil lamp for use on steam railways.

The Houston Ship Channel

By Charles Crotty*

The Houston Ship Channel is the name of the improvement now under way to provide a ship channel to connect the City of Houston, Texas, with the Gulf of Mexico, and to provide a new port for the handling of the growing commerce of the Southwest.

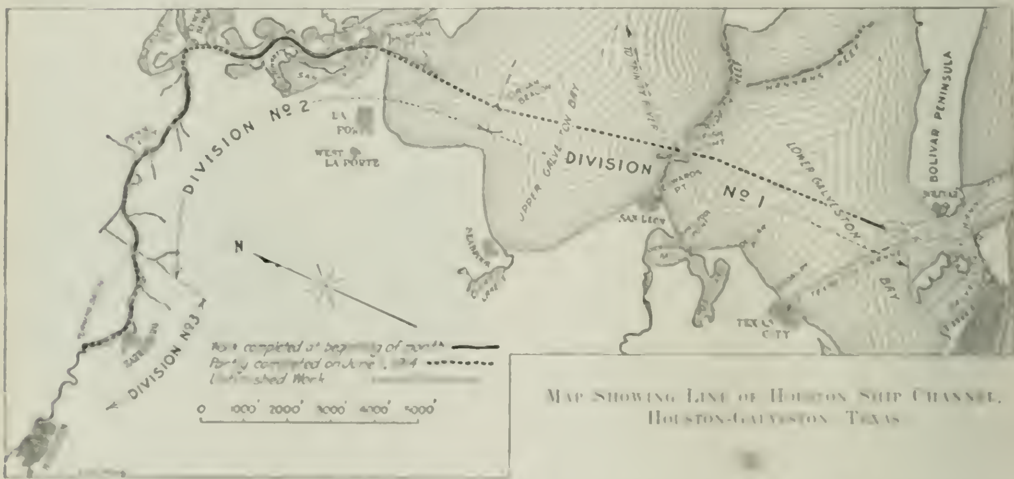
The channel extends from Galveston Harbor opposite the inner end of the jetties and upper end of Bolivar Roads, in a northwesterly direction across lower and upper Galveston Bay, San Jacinto Bay and River; entering Buffalo Bayou at Lynchburg, thence up Buffalo Bayou, past the historic San Jacinto Battlefield, to the foot of Long Beach, about two miles above Harrisburg, ending in a turning basin which is about seven miles below Houston's business center by water and about 4½ miles in a straight line. The total length is 50 miles, of which 25 miles is in Galveston Bay.

In their natural condition prior to improvement, these waterways had a depth of about 9 ft. in the lower and about 7 ft. in the upper Galveston Bay, 10 to 20 ft. in the San Jacinto Bay and River, with low marshy banks and a width of 300 to 800 ft. and 10 to 15 ft. in Buffalo Bayou, with gradually rising banks from 6 to 40 ft. at the turning basin and widths of 200 to 500 ft. The material consists of mud, sand and clay, with some shell through Galveston Bay, sand and clay of varying colors and hardness through the river and bayou.

For convenience and division of contracts the waterway has been divided into three general divisions, No. 1 extending from Bolivar Roads to Morgan Point, about 20 miles long and 2½ miles from upper end of bay at Morgan Point; No. 2 extends to the mouth of Vince's Bayou, and is about 25 miles long, and No. 3 thence to turning basin 5 miles, though what is usually known as the Houston division from turning basin to foot of Main St., Houston, a distance of 7 miles is really a part of Division 3.

The earlier projects for the improvement of this natural waterway, which were adopted in 1871 to 1892, provided for a channel 100 ft. wide and 12 ft. deep, dredging being carried on for a number of years in removing shoals to attain this depth, which was sufficient for the character of vessels then navigating these waters. The Morgan Line began operating steamships and sailing vessels between New York and Houston as early as Apr. 21, 1876, when the "Clinton" passed up the channel and docked at the wharves at Clinton, a few miles below Houston where a branch line of the Texas & New Orleans R.R. connected with the city and other railway lines.

Considerable traffic was carried on for many years, until the increased size and draft of the vessels outgrew the development of the channel and they were forced to seek ports with deeper water.



Map Showing Line of Houston Ship Channel, Houston-Galveston, Texas

The existing project, as adopted in 1899, and modified in 1905, provided for the completion of the ship channel to a depth of 25 ft. and width of 150 ft. across Galveston Bay, with slopes of 1 vertical to 3 horizontal, and width of 100 ft. in river and bayou, with slopes of 1 vertical to 2 horizontal, and a turning basin 600 ft. in diameter on the bottom.

As a part of this project the channel was dredged in 1903-05 to a depth of 18½ ft. under contract with the Bowers Southern Dredging Co., of Galveston, Tex., at the rate of 8.8c. per cu.yd. in Galveston Bay and 11c. per cu. yd. in river and bayou. This depth was obtained as far as Harrisburg.

In 1906, contract was entered into with the Atlantic, Gulf & Pacific Co. for the dredging of Division 3 above Harrisburg and the excavation of the turning basin, at the rate of 19.9c. per cu.yd. Under the various small appropriations from year to year, this work, and the removal of several sharp bends by contract and Government dredges, the entire channel was completed to a depth of

*U. S. Superintendent in charge of field work and supervising dredging operations, Houston Ship Channel, La Porte, Texas.

18½ ft., though the shoaling in Galveston Bay of several feet prevented its use by deep-draft vessels.

In view of the fact that previous appropriations had not been in sufficient amount to insure the completion of the channel to its full depth of 25 ft., its entire length, at one time and make it available for practical use, the citizens of Harris County, through their Deep Water Committee, proposed to the Rivers and Harbors Committee in Congress that they would be willing to contribute one-half of the funds required to complete the work if Congress would make a large enough appropriation and enter into contract for the prompt completion of the project.

Acting on this proposition, Congress, in June, 1910, appropriated $300,000 and authorized contracts for $2,500,000 provided that Houston interests would contribute one-half of the cost of the work, or $1,250,000, and provided that any contract entered into must specifically provide for the completion of the project.

The Harris County Houston Ship Channel Navigation District was then created, taking in the entire county, bonds were voted and sold, the money being turned over to the United States early in 1912.

Under this authorization contract was entered into on June 19, 1912, with L. T. Gaylord, representing the Atlantic, Gulf & Pacific Co., of New York, for the dredging of all three divisions, and providing that on completion of the work the contractor should turn over to the United States a channel the full depth of 25 ft. from end to end, and width of 150 ft. in Galveston Bay and 100 ft. in river and bayou, the slopes to be as steep as the material would stand with payment to be made for excavation within 1 on 3 in bay and 1 on 2 in river and bayou. This placed the responsibility of maintenance until completion of contract upon the contractor, and insured the obtaining of a finished channel its full length at one time.

The contract rates are 6.95c. per cu.yd. in Div. 1, based on estimated quantities of 10,538,000 cu.yd.; 14.9c. per cu.yd. in Div. 2, based on 6,100,000 cu.yd., and 18c. for Div. 3, based on 4,025,000 cu.yd.

Work was started June 15, 1912, with one dredge, a second was added Aug. 4, the third Aug. 31, the fourth Nov. 17 and the fifth on Dec. 28, 1912. The fleet was kept on Divisions 2 and 3 until they were practically completed, Division 1 across the bay being left until last. To June 1, 1914, these five dredges have excavated a total of 20,027,418 cu.yd. of material from within the prescribed cross-section, and a gross total of 28,788,596 cu.yd., including overdepth, outside of slope lines, etc., beside the removal of silt and shoals over about 17 miles of Division 2 in final clean-up of which no accurate record has been kept.

The first cut was completed June 15 and all the fleet massed on the clean-up work, which it is expected will be finished about Aug. 1, 1914, and the channel opened up for navigation about a year and a half in advance of the time allowed under the contract.

The plant engaged on the work is of the most modern and efficient type of hydraulic suction pipe-line dredges, and consists of the following: "Geo. W. Catt," steel hull, 27-in. suction, 24-in. discharge; "Texas," "Washington" and "Pensacola," with wooden hulls, 22-in. suction and 20-in. discharge pipes, belonging to the Atlantic, Gulf & Pacific Co.; and the "Galveston," wooden hull, 22-in. suction, 20-in. discharge, and the "Houston," a new wooden hull, steam turbine, electrically driven pump and cutter engine, 24-in. pump and 22-in. discharge pipe, belonging to the North American Dredging Co., of Galveston, Tex.

The largest output for any single month was made by the "Texas," which excavated 1,261,646 cu.yd. of mud, shell and sand, completing a channel 150 ft. wide and 9100 ft. long, pumping through about 1200 ft. of pipe line working in Galveston Bay. The dredge "Houston," equipped for high speed and lifts, handled 222,861 cu.yd. through a pipe line 3800 ft. long and with a lift of 36 ft. while working in the turning basin. A large part of this material was hard red clay, the rest mud and sandy loam.

For the maintenance of the channel after the completion of this contract, two large hydraulic suction-pipe-line dredges are being built under contract with the Bowers Southern Dredging Co., of Galveston, Texas, at a cost of $320,000 for the two. The steel pontoons, pipe lines and other equipment will probably bring the cost up to about $400,000, of which one-half is contributed by the Navigation District.

The completion of this channel will allow vessels to reach a harbor 50 miles closer to the point of production of the greater part of our commodities, and to form connection with the seventeen railways centering at Houston, will provide for the expansion of the growing business of the Southwest and create a great inland, fresh-water harbor, develop industries along its route by furnishing cheaper transportation for raw and finished products, and with pipe-line connection to the fuel-oil fields of Texas and Oklahoma, the opening of the new iron-ore fields of northeast Texas, the early completion of the Intra-Coastal Canal enabling coal barges to be brought from the fields of Alabama, and along the Ohio River, it is expected that a new era of business development in manufactures will take place.

Cotton is still the greatest single item of export and about 400,000 bales have been handled over this channel each year by barges, while about 5,000,000 bales per year have passed through Houston to be loaded on vessels at Galveston and Texas City. It is expected that Houston, with the many compresses and warehouses of the most modern fireproof type that are now built along the channel and between the turning basin and the city, will be able to load a great deal of this commodity into vessels in her own harbor.

The recently created Harbor Board of Houston is now working up plans for the construction of the latest type of wharves, warehouses and freight-handling machinery, to be erected in units as the needs of commerce justify, beginning at the turning basin, and working down the channel. As the waterway connects with other streams and lakes there is available for improvements about 75 miles of water front, with close rail connection, and with its ultimate enlargement as the business grows and the Western country becomes more thickly settled and productive the possibilities for the future as a port are unlimited. Of course, Houston expects to reap a considerable share of the trade developed for this section of the country by the opening of the Panama Canal.

⁂

Street Pavement Work in Zanesville, Ohio, will amount to nearly $200,000 for the period since the great flood of 1913, according to statistics recently published in the local newspapers. About $50,000 is being spent on the sewerage system.

Putting 13-In. Pins in Place of 10-In. Pins, Williamsburg Bridge

By D. E. Hovey*

In the May 14, 1914, issue of Engineering News, reference was made to "the sensational performance of taking out a 10-in. bridge pin and putting a 13-in. pin in its place" on the Williamsburg Bridge, and a brief outline of the general method adopted was given. The writer believes that a further account of this unusual piece of work will be of interest to engineers.

The Problem

The Williamsburg suspension bridge, crossing the East River at New York, is so designed that the portions of the main cables extending from the tops of the towers back to the anchorages carry no load from the land spans. These spans are supported by steel towers. Fig. 1 shows the general arrangement. The stiffening trusses of the main span are continuous between the towers and are supported on rocking links at the towers; the trusses continue landward of the rocker supports for a distance of $20\frac{1}{2}$ ft., or one panel, as cantilevers. In the original construction, these cantilevers consisted of a single triangle at each end of each truss, L-29 L-30 U-30, in Fig. 2, carrying the land span at L-29 by a 10-in. pin.

On account of this unusual construction, all motions of the center of the main span up or down, due to contraction, expansion, or live-load variations, cause points L-29 to move down or up. Also, contraction or expansion of the stiffening trusses causes points L-29 to move horizontally toward or from the towers (the stiffening trusses being free to move on account of their rocker support); such horizontal motions are communicated to the land spans at both ends of the bridge, and cause tension or compression across the points L-29. These stresses are further increased by horizontal or wind stresses, since the main lower chords are also the wind chords.

The general strengthening of the bridge for subway trains, recently completed, required various additional members and connections. Those at panel-point 29 are shown in Fig. 2. The original cantilever has been strengthened by the addition of triangle U-29 L-30 U-30. A portion of the load from the land span has been permanently transferred to the new triangle by means of a new transverse lattice truss attached to the land span at point U-29 and resting on adjustable wedge bearings on the new cantilever triangles at U-29. This construction is shown by Fig. 2.

It was also necessary to replace the old 10-in. pins at L-29 by new pins 13 in. in diameter. To do this, the old 10-in. pin-holes must be enlarged to 13 in. in diameter, with all connecting main members in position. On account of the difficulty of removing the chips produced by the boring operation by any other method, it was decided to remove the old 10-in. pins and enlarge the holes by open boring and the use of a boring head fed along a boring bar, if a safe method of procedure could be developed.

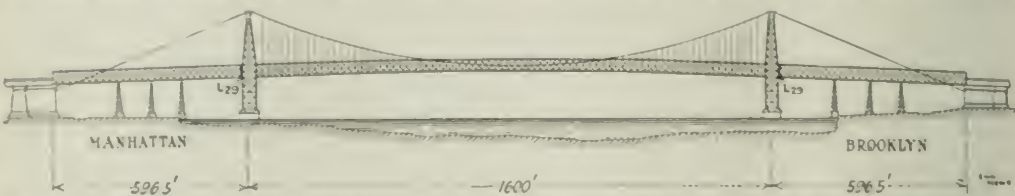


Fig. 1. The Williamsburg Bridge as Strengthened by Additional Towers in Shore Spans

*Assistant Chief Engineer, American Bridge Co., 30 Church St., New York.

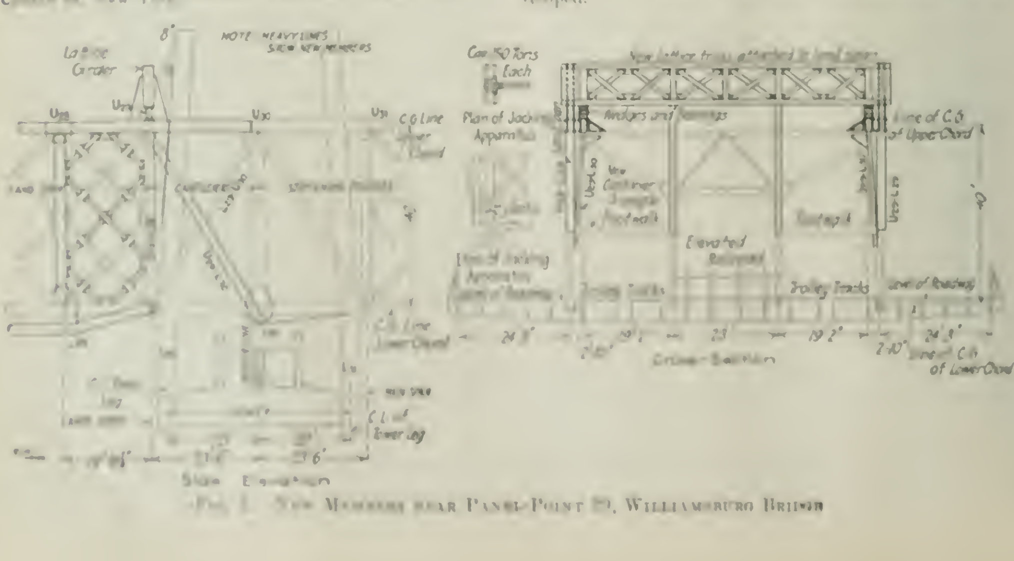

Fig. 2. New Members near Panel-Point 29, Williamsburg Bridge

To relieve the 10-in. pins of vertical load, the new wedge bearings at U-29 could be temporarily replaced by hydraulic jacks and blocking, by which means the load of the connecting spans could be temporarily transferred from the old cantilever triangle L-29 L-30, U-30, to the new triangle U-29 L-30 U-30, in Fig. 2. Longitudinal movements at L-29 could be temporarily suppressed or at least reduced, by stopping trolley and vehicular traffic during the early morning hours of certain nights. As the bridge is a very important traffic link, it was imperative to make the stoppage of traffic as brief as possible. This demanded the development of a device to enlarge the holes quickly, and effective guarding against all unnecessary delays during the boring operation.

Locking Joint L-29

It was obvious that the boring, with the old pins removed, would not be successful unless the connecting members were held in fixed relative positions during the entire operation of removing the old pin, enlarging the holes and driving the new pins. It was also necessary to arrange for connecting the new wind chords L-28 L-29 on the new pins, and further to provide for stresses at the joint due to temperature changes and lateral wind pressure.

The lower chords were prevented from moving toward each other by driving wedges in the clearance spaces between them. They were held from moving apart by two tie-rods $3\frac{1}{2}$ in. in diameter, fitted to temporary brackets on their bottom flanges. The three intersecting members of the land span were already connected by heavy gussets inside of the posts L-29 U-30. But the members L-29 L-30 and L-29 U-30 of the old cantilever were connected only by the pin; therefore, triangular brackets were provided to attach these members rigidly together and to stop relative angular motion. It was then only necessary to furnish heavy struts to join the land span to the cantilever in order to stop all relative motions at this joint. To prevent the thrust of the boring head from pushing the members together, transversely with the trusses, small wedges were driven in the clearance spaces between them. The design of these devices for locking joint L-29 against all motions is shown in Fig. 3.

To further guard against any possible motions at L-29, the upper chords of the land span and the stiffening truss cantilever were locked by struts and tie-rods, as also shown in Fig. 3.

All of these temporary parts to lock the joint against motions were carefully fitted up on the bridge in advance and adjusted loosely so as not to interfere with the normal movements of the bridge until everything was ready for the removal of the old pins.

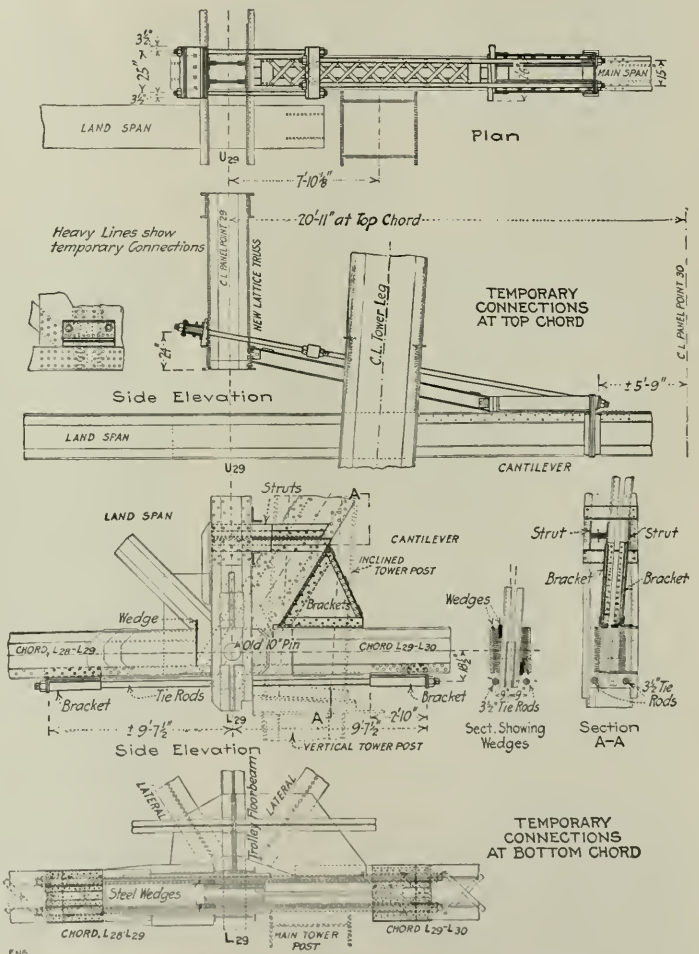

Fig. 3. Temporary Connections to Hold Joint L29 Rigid While Boring Out the Pin-Hole

It was found that the old pins could not be backed out, as they had been driven very tight and some corrosion had occurred, thoroughly cementing them into the ends of the holes. The pins were therefore collapsed by boring axial holes along the horizontal diameter and chipping away the walls between the holes. The half pins were then loosened and wedged back in their original positions, so that when all was ready they could be quickly removed.

Boring Machine

The design of the boring machine for enlarging the holes presented an unusual problem. Pins L-29 are very near the main tower legs, and the clearance was so limited that the machine had to be placed on the landward side of the hole. This meant inverting the machine from right handed to left handed when changing from south truss to north truss or vice versa. It was vital that the machine should be so made that it could be attached to the bridge and carefully aligned in advance, and clearance provided so that the old pin could be taken out, the boring bar put in and removed, and the new pin driven without disturbing the main frame and the alignment of the machine. It must be as compact as possible to avoid having to cut a large hole in the roadway floor. As the amount of steel to be bored out was about 1300 cu.in., ample strength, stiffness and power were necessary. The removal of 1300 cu.in. in one hour (over 6 lb. per min.) runs in a groove milled in the bar, and is driven by gears in the feed head O. The fixed pinion P is boxed in the plate R, which is attached to the fixed boring-bar box K by studs S. The shaft carrying pinion P is fitted with a handle which was locked to the plate R, thus providing automatic feed of the screw due to rotation of the boring-bar. To stop the feed, this handle could be unlocked, allowing gear P to rotate, thus stopping the action of the feed train.

In ordinary practice, the tool head is fed along the bar toward the feed mechanism. Clearances prevented this being done, and to keep the feed-screw in tension, it was necessary to provide a thrust bearing at the extreme outboard end of the bar. This thrust bearing is of bronze, with 12 collar bearings, each lubricated by means of a central oilhole in the boring bar, with branches to each collar, and supplied from a grease cup in the end of the bar.

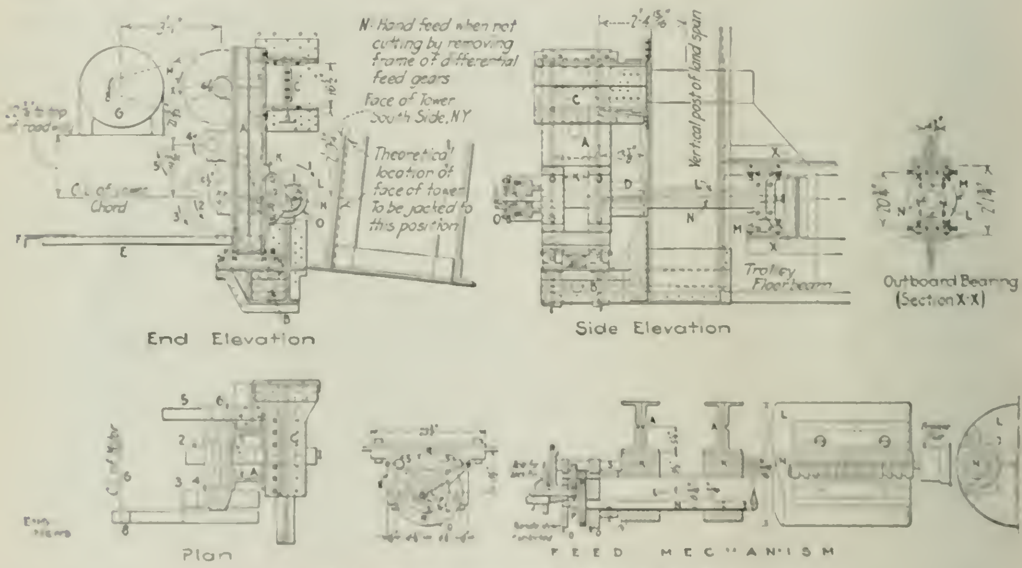

FIG. 4. SPECIAL PIN-HOLE BORING MACHINE

in the form of spiral chips, required ample space for their successful removal.

To provide for convenient attachment to the bridge superstructure and for assembling alternately right and left, the frame of the machine (Fig. 4) is a structural-steel post A. This was attached to the bridge by steel brackets B, C and D and braced by the strut E, bolted to a bracket bolted to lower chord L-28 L-29. On the back of the frame is a gear train, 2, 3, 4, 5, 6 and 7, driven by a [illegible]-hp. motor G, by a [illegible] Morse chain H, engaging sprockets 7 and 8. The front of the frame is left clear for the boxes K and [illegible] of the boring bar I. To the stringer floor-beam was clamped an outboard bearing M, one-half of which could be removed for inserting and removing the boring-bar without disturbing the alignment of the bearing.

The boring bar is $6\frac{1}{2}$ in. in diameter, and 7 ft. 11 in. long as assembled. A feed screw N, $1\frac{3}{4}$ in. in diameter, The boring head carries seven self-hardening, high-speed steel tools. Six of these were so set that each made a circular cut $\frac{1}{4}$ in. wide. The tool taking the cut from 10 in. to $10\frac{1}{2}$-in. diameter was set in advance of the next from the center and so on for the six. The seventh tool took a light finishing cut. The assembled boring-bar as it was handled in and out of the hole is shown by photograph, Fig. 5.

The Boring Operation

All preliminary operations having been completed in advance, on the night set for removing the various pins a force of picked men, each carefully instructed in his duties and working from a carefully prepared schedule of operations, was assembled on the bridge and at the time fixed to begin work all trolley and vehicular traffic was stopped and the work begun. At each of the four points the work was completed well within the time allowed.

Fig. 5. Boring Bar

The following gives the record for each point:

Point	Date 1914	Traffic stopped	Traffic resumed a.m.	Total time hr.	Total time min.	Time first cut min.	Av. hp.	Steel removed, lb., per min.
Manhattan south......	Apr. 12	1.00 a.m.	5.50	4	50	60	26.9	6 15
Manhattan north......	Apr. 26	25th; 12.20 p.m.	3.45	3	25	58	22.6	6.35
Brooklyn south......	May 16	15th; 12.25 p.m.	3.30	3	5	57	22.5	6.46
Brooklyn north......	May 29	28th; 12.15 p.m.	3.30	3	15	58	21.4	6 35

The boring machine assembled on the bridge is shown by the flashlight photograph, Fig. 6, in which the boring bead is seen just entering the vertical post.

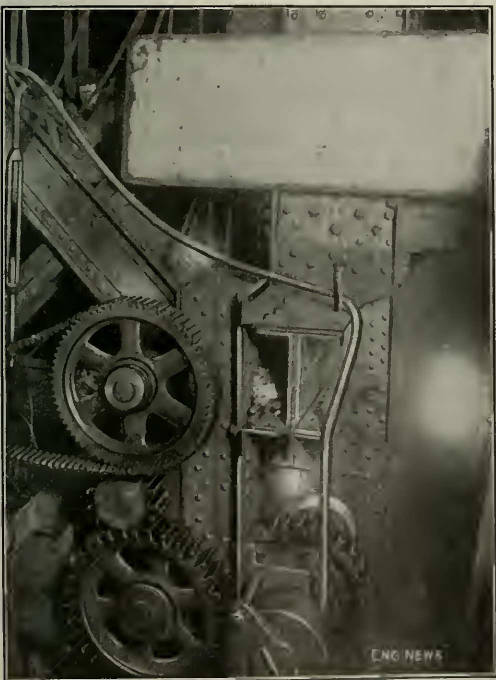

Fig. 6. Boring Machine

This work was done by the Snare & Triest Co., of New York, under a contract for strengthening the end spans of the Williamsburg Bridge, and under the direction of the Department of Bridges of the City of New York.

The devices for locking joint L-29 against motion, and the boring machine, were designed by the writer, who was retained by the Contractors as Consulting Engineer.

The boring head was developed by Martin Joachimson, Assistant Engineer of the Bridge Department, in consultation with the writer.

The Old Wooden Bridge

[The excellent parody on Longfellow's "Evangeline," printed below, we take from the June "Bulletin" of the Iowa State Highway Commission, which credits it to the Manchester (Iowa) "Mirror," where it was printed anonymously. Such bridges as are well described in the verses exist, however, in hundreds of country towns beside Manchester.

It is fair to say, however, that while there are many such rotten and rickety wooden structures which ought to be replaced in the interest of safety, there are still localities where the wooden truss bridge is probably the best structure that can be built; and many old wooden bridges, properly protected from the weather, have had a useful life longer than that of many steel bridges.]

This is the structure primeval; the tottering beams and the timbers,
Patched up with boards and with fragments, old, frail and fearful to look at,
Stand like ruins of Rome, with memories sad and prophetic;
Stand like a pile of junk that no one will take for the hauling.
Loud from the rickety boards, the ancient nails all together,
Shriek, and in accents disconsolate, answer the curse of the traveler.

This is the structure primeval; but where are the hands that in old times
Wielded the hammer and saw, and fashioned its lines full of beauty?
Where are the boys of the village that leaped from the rail in bravado?
Where are the maidens of those times, who made sand cakes in its shadow?
Gone to their final home, but the bridge in rotting decadence,
Marks for all who can see, the date when our city was founded.

Dear to the hearts of the Council is this relic received from the ancients;
Precious is each piece of punk secured by rust to the ruin;
Ten-penny nails in rich measure adorn every spot that will hold them;
Boards of all kinds, wire and rocks give grace in fullest profusion.
Think not that money is lacking to furnish a structure more modern—
Money is raised every year, and spent where the aldermen wish to;
Near to their hearts and their homes have they laid out their lines of improvement,
Trim and neat is our city, wherever the "drag" has been working.
No, this bridge is preserved, a dangerous trap for the user,
Likely to cost many times the price of a new and secure one,
A monument, always to stand, to the wisdom and pride of our Council,
Showing the different styles of nailing supports to a ruin,
Showing to all the world the power that lies in the Council.

Field and Office

A Drafting-Room Innovation: Drawing with Steel Point on Coated Paper

A proposal to revolutionize drafting-room practice is just being put forward in practical working form. Drawing paper and tracing cloth, pencil, pen and ink are to be abolished. In their place is to come a dark-coated fabric and a steel scriber; to make a drawing, use the scriber as a pencil and scribe the drawing on the coated fabric, producing white (and *translucent*) lines on the dark (and opaque) fabric. Blueprints are made direct from the finished drawing.

Charles H. Little, of Cleveland, Ohio, worked out the new appliances, in pursuit of the idea that double work—drawing and tracing—is superfluous and ought to be abolished. He says that very many trials and experiments were required to find the right base (paper or fabric), the right coating, and the right scriber. Now that the work has reached the point of practical success, Mr. Little's company, the Universal Drafting Machine Co., Cleveland, is putting the fabric and scribers on the market. The fabric is called Unidraft Fabric, possibly in reference to the elimination of double work.

The Fabric—The surface of the coated fabric is resistant enough that it does not become scratched in working on it and handling it; yet it takes the scriber marks easily, with just enough resistance to permit of varying the width of line by controlling the scriber pressure. Figs. 5 and 6 show lines of different strengths. The surface is dull, and does not reflect a glare into the eyes. Also, the color (dark brown) gives it one great advantage over paper and tracing cloth: the eye is rested where it looks at the general surface, and only the narrow width of the scribed lines is seen. This not only is restful to the eye in a general way, but it makes it very easy for the draftsman's eye and mind to follow the drawing, for the same reason that a lantern at night strikes the eye much more quickly and surely than does a black object in daytime. The fabric is claimed to eliminate the eyestrain question (always important with draftsmen), and that the unsolved problem of satisfactory drafting-room lighting ceases to exist.

A cloth base for the coating is preferred to a paper base, although the latter was tried out extensively in the course of the development work. The durability due to the cloth base, and the freedom from soiling due to the dark, nonabsorbent surface, are distinct advantages where a drawing is worked on for a length of time.

The Scribers—Various forms of scribers have been tried. The one shown (magnified three or four times) in Fig. 1 is the preferred form, being most widely adaptable. It is held with the triangular side leading, the beveled face standing about vertical (hardly inclined forward, as in Figs. [illegible] and [illegible]); the trick of using it is learned easily, as we have had occasion to prove.

Circles are drawn just as easily as straight lines, scriber points being inserted in compasses and bow instruments. Fig. 2 illustrates the work of drawing circles with bow compasses. Here also the width of line is controlled by pressure variation, same point being used throughout.

The scriber shown answers all requirements as to drawing lines. It is also satisfactory for lettering, but in this part of the work individual preferences and habits of the hand are a consideration. A scriber of cross-shaped section, ground off on a bevel like the one shown, is also an efficient tool in lettering. The important fact as to lettering is that a little practice enables one to letter just as rapidly and neatly with the scriber as with the pen.

By eliminating ink, the work of drawing on this fabric is clean, quick work; the draftsman does not wait for ink to dry, or run the risk of making a smear. This fact alone means great saving of time, enough to make up for any other differences of facility between scriber and pen.

Erasures—To erase lines or marks from the fabric, it is only necessary to draw or mark over them with pen and ink. The white under-coating takes the ink; the black or dark-blue coloring of the ink is hardly distinguishable against the brown, in looking at the surface, while for blueprinting purposes the erasure is completely effective.

Another line or mark can be made over the erasure, by again using the scriber, which cuts away the ink, together with some of the under-coating.

The erasure process is much quicker and easier than erasures on tracing cloth, and in certain cases may be quicker and more convenient than erasing pencil marks or lines. Thus, taking out part of a line in a crowded part of a drawing is easy with the fabric, while in pencil work it will require redrawing some lines erased unintentionally. Converting a full line into dashed or dotted is also very easy in the case of the fabric.

The facility of erasure is apt to be an important question with those who are accustomed to making drawings by the trial-and-erasure process. For work of this kind, the applicability of the fabric is rather limited. Its primary field is that class of work in which the arrangement and layout of the drawing is well fixed in advance, as in detail work, shop drawings, etc. Especially where the edges of the rules bear scales, as in the drafting machine, there is a constant guide to the line work which is of value in the most efficient use of this fabric.

Blueprinting—The fabric prints practically as fast as tracing cloth. The prints are clear and sharp, being quite as contrasty as ordinary blueprints. Being made from a white-on-black drawing, they show blue lines on a clear white ground. It is possible to make good white-on-blue prints from the first prints.

Cost—The Unidraft Fabric costs "from 25 to 30% more than the combined cost of the drawing paper and the tracing cloth which it replaces." The makers intend to put it out regularly in sheets, on the idea that rolls are wasteful.

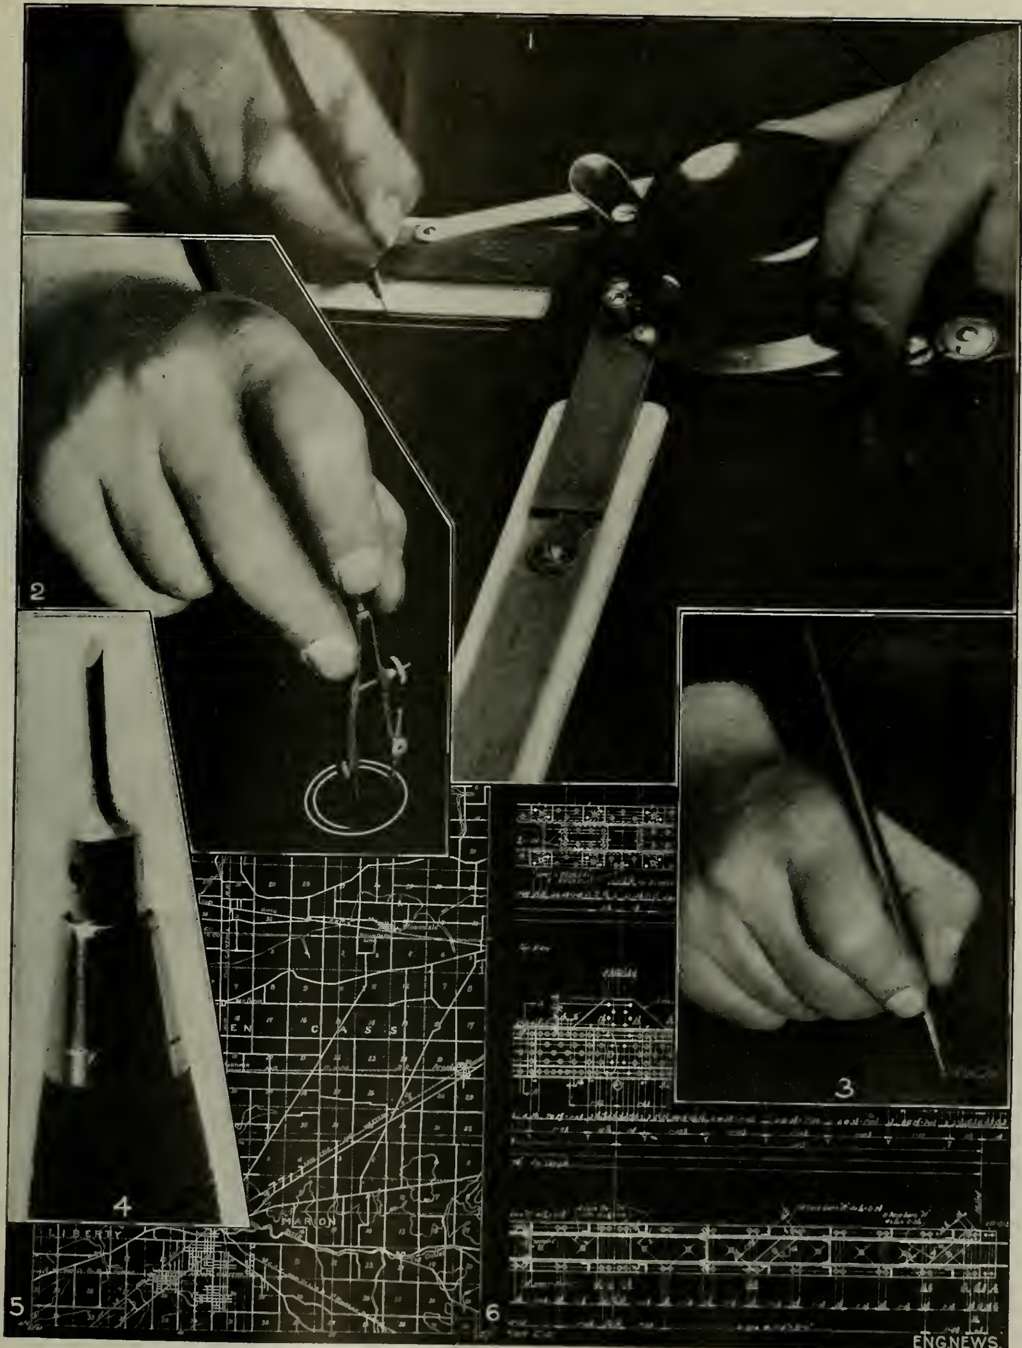

Fig. 1. Working on Unidraft Fabric with the drafting machine. Fig. 2. Scriber point in bow compasses for circle work. Fig. 3. Lettering; with a little practice the lettering becomes as perfect as ink or pencil lettering, and it is fully as rapid. Fig. 4. Scriber point for line work, magnified several times. Fig. 5. Part of a map drawn on the fabric, showing fine contours and heavier road lines, irregular lines, etc. Fig. 6. Part of a structural-steel drawing, with close line work of fine and heavy width, crowded lettering, and small bow-compass work. (Figs. 5 and 6 are reproduced direct from photographs of finished drawings on the fabric.)

THE NEW FABRIC AND SCRIBER FOR MAKING SINGLE-PROCESS DRAWINGS

A Very Large Block and Hook

Readers of current engineering literature have probably noted the gradual growth in six-sheave blocks during the past four years. The one here shown differs from that described in ENGINEERING NEWS of Jan. 5, 1911, in having ¾-in. instead of ½-in. plates. The block and hook illustrated are to be used on a 50-ton Mitchell derrick car manufactured by the American Equipment Co., for bridge erection.

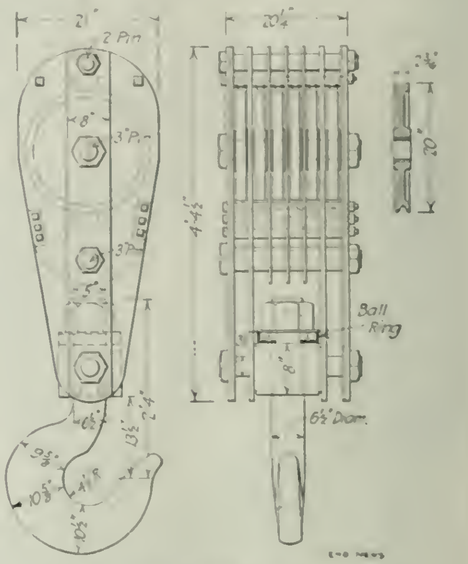
BIG SWIVEL HOOK FOR 50-TON PATTERSON BLOCK

The total weight of the block is 2500 lb. Its tail bolt is 2 in. in diameter; the sheave pin is 3 in. in diameter with a ½-in. dog to prevent turning. There are four heavy cast-iron separators between the ¾-in. plates. There are six sheaves, 20 in. in diameter, for ⅞-in. wire cables. The block is fitted with a ball-bearing hook, forged from an 8x8-in. forging billet, flattened to 10⅝x6½ in. The hook, with supporting beam, weighs 1040 lb.

The block was designed and built by the W. W. Patterson Co., Pittsburgh, Penn., for the Illinois Central R.R. It was delivered 23 days after the placing of the order.

Trench Backfilling Machine

A backfilling machine for trench and other work is now being introduced, which travels at the side of the trench and scoops in the dirt from the dump pile left by the excavator. It has a 10-hp. hoisting engine and vertical



DETAILS OF LARGE HOOK BLOCK

boiler mounted on a steel frame carried by wide-tired traction wheels and propelled by its own power. It is about 10x10 ft. over the wheels.

Across the front of the machine extends a horizontal frame 16 to 40 ft. long, according to requirements, along which travels a carriage to which is attached a scraper plate. The carriage has wheels riding upon the frame

TRENCH-BACKFILLING MACHINE

(The scraper or bucket is attached to a carriage traveling on the horizontal frame and operated by a cable.)

and bearing against it laterally, the wheels having deep flanges so as to resist the vertical and horizontal thrust of the scraper. To the carriage are attached the ends of a wire cable which leads over horizontal sheaves at the ends of the frame, and then back over other guide sheaves on the front of the main frame, and thence to the engine drum. The scraper is L-shaped in plan, 24 in. wide and 36 in. high, and the carriage forms a back plate 36 in. long. It has an adjustable bottom plate or apron.

In operation, the machine travels near the side of the trench, and the scraper runs to and fro, scraping material from the dump pile into the trench. At each end of its travel the scraper strikes an adjustable trip, thus automatically reversing the engine. It makes 10 to 15 strokes per minute. The distance from the center of the trench to the center of the machine is equal to half the length of the long frame which carries the scraper. The machine has backfilled about 300 yd. in a single day, when working against a clay spoilbank that had stood for four or five months during the winter and had become hardened.

The machine is the invention of F. L. Monahan, of Joliet, Ill. It is intended particularly for use in connection with his trenching machine, and is a development of his earlier backfiller, in which a scraper was hauled by a cable from an engine on the opposite side of the trench, the scraper being run back by men handling and guiding it. This was described in our columns some time ago. The new machine is being built by William Heggie, of Joliet, Ill.

Cleaning Old Paving Brick by Compressed-Air Hammers

By Charles S. Butts*

The construction of the Rocky Branch joint district sewer at St. Louis, Mo.,† involved the disturbance of a considerable extent of paved street. The work is 5724 ft. long (on Blair, Palm and Glasgow Aves.) and was done by the James Black Masonry & Contracting Co., at a price of about $500,000.

Of the total length, 4600 ft. was in streets having brick paving grouted with cement, the paved width being 17 to 30 ft., and the total paved area being about 10,000 sq.yd., with about 530,000 brick. The specifications require the contractor to repave the streets and leave them in as good a condition as before the construction of the sewer.

The question was (and always has been) whether it pays to clean vitrified paving brick (cement grouted) for use in repaving streets. In cleaning them by hand a man can clean about 300 a day. And at $4.50 per 1000 (which was paid for this method of cleaning) he would only make $1.35 per day. In order to make it any inducement to clean them by hand about $9 per 1000 would have to be paid. The contractor finding this method not only slow but also unsatisfactory, abandoned the hand-cleaning method and adopted the following machine method which has proved very satisfactory.

An old vacuum-cleaning wagon was obtained and set up in a convenient location at the pile of brick to be cleaned and used as an air compressor. A ½-in. supply pipe was run to a cleaning board, and to it were connected ¼-in. hose, to each of which was attached a 6½-lb. stonemason's vibrating air hammer. The hammers had 1-in. chisel points for cleaning the portland-cement grout from the brick. A bench was built and about 70 bricks placed on it with the side upward. One side and one end were cleaned first; then they were turned and other side and other end were cleaned. As there was no cement on top or bottom it required only one turn to complete the cleaning. The capacity of this particular machine is three hammers, and, as the following table shows, the more hammers operated, the cheaper the brick can be cleaned.

	1 hammer	2 hammers	3 hammers
No. brick cleaned per day	1200	2400	3600
Cleaning brick, $2 per 1000	$2.40	$4.80	$7.20
Turning brick, $1 per 1000	1.20	2.40	3.60
Gasoline for machine	1.40	1.40	1.40
Cost	$5.00	$8.60	$12.20
5% for care of tools, etc.	0.25	0.43	0.61
Total cost	$5.25	$9.03	$12.81
Cost per 1000 brick	.4.375	$3.762	$3.3558

The difference in cost per 1000 is due to the gasoline used, it costing $1.40 per day to run the machine whether one, two or three hammers are used. To the above costs per thousand for cleaning must be added about $2 for hauling to the pile and back on the street, which would make the cost (using the two-hammer price) $5.76 per 1000. This against $16 per 1000 for new brick makes a saving of $10.24 per 1000 for the small-size brick (2¾x4x8¼ in.). The large paving brick now in use (3¼x8½x4⅛ in.) would cost about $4.50 per 1000 to clean, plus $2 for hauling, making $6.50 per 1000 against $22 for new brick, a saving of $15.50 per 1000.

Cleaning Cement Grout from Paving Brick with Pneumatic Chisels at St. Louis, Mo.

*First Assistant Engineer, Sewer Department, St. Louis, Mo. (In charge of the construction of the Rocky Branch joint district sewer).

†"Engineering News," Apr. 16, 1914

An Editor's Apology—The Secretary of the Oklahoma Society of Engineers prefaces Vol. 1 of the Society's "Transactions" with the following note:

Able contributors will be abashed to learn that their remarks have been garbled beyond recognition or omitted entirely. Many papers are missing and requests for brief synopses have generally brought no replies.

If the transactions are not worth perusing it must be the fault of the Society for entrusting the work to

THE SECRETARY.

Rapid Excavation, Foundation of Citizens' National Bank, Los Angeles

The work of clearing up the site of the future 12-story Citizen's National Bank Building, at the northwest corner of Fifth & Spring St., Los Angeles, Calif., began on Apr. 28, but difficulty in acquiring certain buildings on the site prevented excavating going forward until June 8.

The lot fronts $115\frac{1}{2}$ ft. on Spring St. and is 155 ft. deep. There will be eight cantilever footings, each containing 2600 cu.ft. of concrete and 4 tons of steel reinforcement, with bottom of cantilever 40 ft. below the sidewalk. Forty piers with pedestals are to be placed, averaging 20 cu.yd. of concrete and 1500 lb. of steel each. A sub-basement with floor 30 ft. below the sidewalk occupies an L-shaped portion of the lot adjoining the north and west property lines. The remaining portion of the building will have a basement with floor 13 ft. below sidewalk.

When once started, the excavating was pushed rapidly, and was completed in about one month.

Excavation was started by a steel stiff-leg derrick, of 70-ft. boom, using buckets of 2-cu.yd. capacity, shown in Fig. 2. The deep excavation necessitated a comparatively long boom, but made its operation difficult on account of the limited space. The buckets were loaded by hand, lifted by the derrick and dumped into a 30-cu.yd. bunker placed 12 ft. above the sidewalk at Spring St. The earth was removed from the bunker by motor trucks, which carried it about two miles, requiring 30 minutes for the round trip. The derrick could take out 500 cu.yd. in 24 hr.

Old brick walls abutting the site were shored and underpinned. At the left of Fig. 1 is shown a two-story brick wall, which extends about 8 ft. below the sidewalk. This wall was carried down in some places to a depth of 40 ft. The underpinning required the use of 300,000 bricks.

Fig. 3 shows the retaining-wall necessitated by an alley on the west. This retaining-wall was of reinforced concrete, 40 ft. high, 3 ft. thick, with a reinforced footing 8 ft. wide. The wall was heavily shored during construction.

All the buildings on the site had been removed by June

Fig. 1. Site Shortly after Start of Work

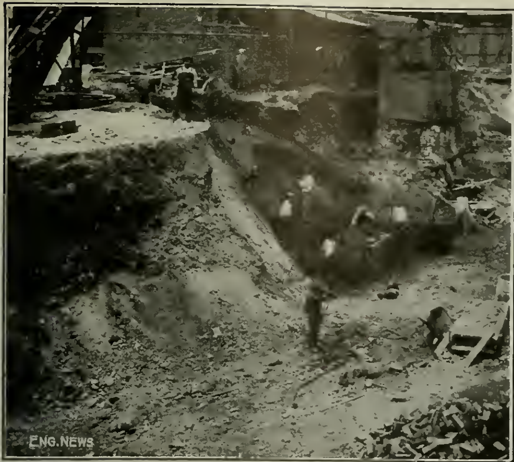


Fig. 2. Shoveling Into Derrick Buckets

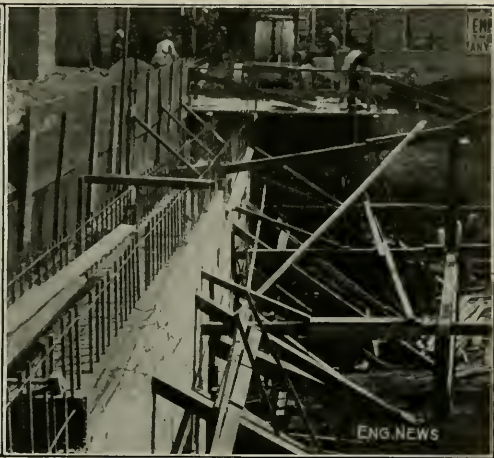

Fig. 3. Concrete Retaining-Wall with Timber Shoring

12, when teams were put to work on the shallow portion. The derrick continued in service until the night of June 14, when a cable broke. As the deep excavation was practically completed at this time, the derrick was removed and the work finished by teams. A wagon of 1½-cu.yd. capacity was loaded in 8 min. by 21 shovelers (mostly Mexicans), and hauled to the street in 2 min., with the assistance of two snatch teams. The work was scheduled for completion July 1, and will actually be completed shortly afterward. Extension of time was necessary and allowed, on account of delays caused by conditions beyond the control of the contractor.

Fig. 4. Excavating with Teams on Shallow Portion

The excavation amounted to 15,000 cu.yd.; while 3000 cu.yd. of concrete and 70 tons of steel reinforcement were placed. Fig. 4 shows progress on the foundation and excavation up to June 29, and the firm character of the soil.

The work has been pushed night and day, and according to the engineer would have been completed two weeks earlier had the lot been clear of buildings at the start. After all the leases were purchased, the last three buildings were wrecked in 24 hr.

The excavating was done by the Sound Construction & Engineering Co., Seattle, Wash., whose engineer in charge is J. T. Walsh.

Sub-Irrigation and Drainage for Golf Greens

To keep the golf greens of the parks in good condition during the summer, the Park Department of St. Louis has constructed them with a sub-irrigation system, supplemented with a drainage system for the removal of excess water.

Along one end of the green is laid a 1-in. iron header

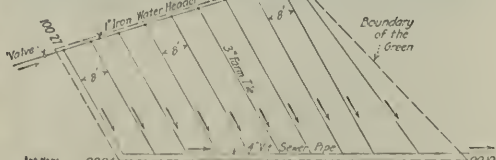

Fig. 1. Plan of Golf Green, with Sub-Irrigation and Drainage System; Park Department, St. Louis, Mo.

pipe, with 4-in. branches of $^3/_8$-in. brass pipe inserted at intervals of 8 ft. Each branch ends in an elbow, turned downward, and enters the upper end of a line of 3-in. farm drain tile laid with open joints and having a slope of about 0.5%. These lines of tile connect with a 4-in. vitrified sewer pipe laid along the opposite side of the green, this pipe extending to a sewer connection. The 3-in. tiles are laid in a 5-in. bed of sand above, which is 12 in. of soil, and the grass roots run down to the bed of damp sand and get an ample supply of moisture.

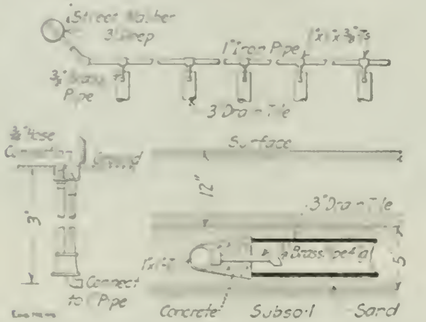

FIG. 2. DETAILS OF SUB-IRRIGATION FOR GOLF GREENS

The water is supplied by a 1-in. pipe laid 3 ft. deep and connecting with a McNamara street washer which serves as a valve box. From the top of the riser pipe of the street washer a $^3/_4$-in. hose connection is made to the

FIG. 3. PREPARING THE SAND BED OF THE IRRIGATION SYSTEM FOR GOLF GREENS

(The [illegible] pipe has a short branch into each line of tile, the tile drains being bedded in sand and the whole covered with 12 in. of earth)

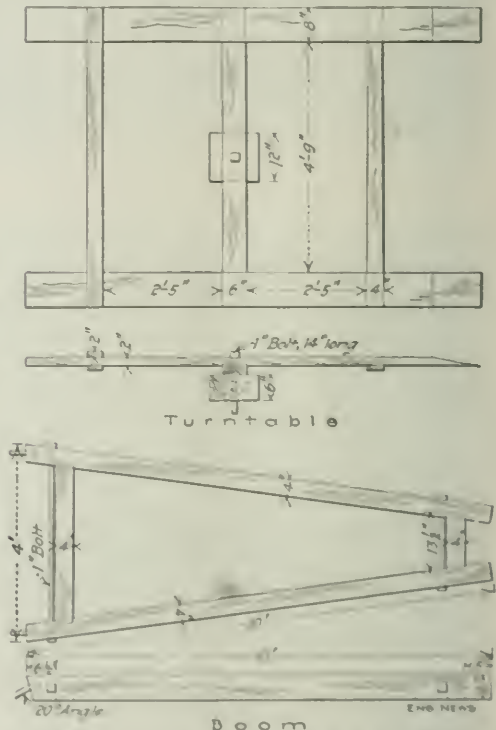
hose header of the irrigation piping. The irrigation is done at night usually.

A number of greens have been equipped with this system. It was designed by [illegible], Superintendent of Construction of the Park Department, and the work has been done by the park forces under his direction.

A Bridge Repair Derrick

A truck derrick for bridge repair and maintenance designed by H. Walker, master carpenter of the Cincinnati, Lebanon & Northern Ry., is illustrated by the accompanying drawings. The derrick consists of a truck carrying a platform upon which is a small windlass and boom, with blocks and tackle. Its object is to facilitate the handling and renewal of stringers, and other heavy timbers in the maintenance of wooden bridges.

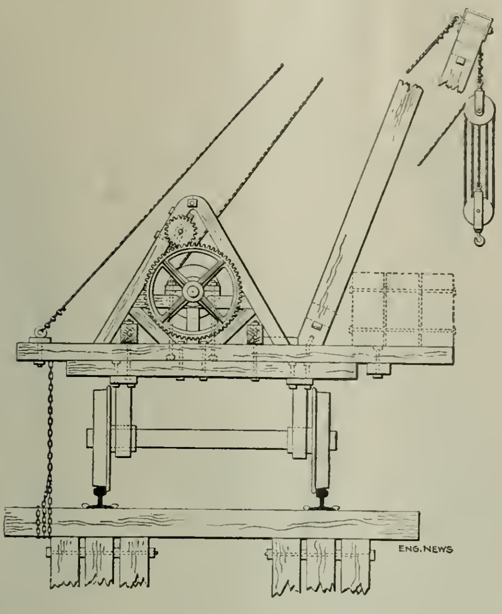
Edmund Feldman, 3591 Wilson Ave., Cincinnati, Ohio, who sends us this information, states that with this tool four men can handle and replace a 16-ft., 3-ply chord



DETAILS OF BOOM AND TURNTABLE OF THE TRUCK DERRICK

in a half-hour. To perform this operation, the wood guard rail above the chord is first removed and the bolts connecting the chord to the corbels are taken out. The track rail is then jacked up about 6 in., carrying the ties with it, which gives free access to the stringers. The truck derrick is run over the bridge to about the center of the stringers to be removed, and chained down to prevent tipping during lifting. A chain is placed around the chord which is then hoisted and placed on the truck in the location provided for that purpose. The truck is then unchained and pushed off the bridge where the stringers are unloaded. The new chord is then picked up by means of the derrick, pushed onto the bridge, and lowered into position. The bolts and guard rail are then

replaced. A turntable is provided so that the truck can be used on the other side of the bridge without dismantling the derrick.



Elevation of a Truck Derrick for Bridge Repair

The derrick was built by Mr. Walker for his particular needs and is not manufactured commercially.

Expensive Repairs to an 8-In. Water Main, 40 Ft. under Water*

About two years ago, an 8-in. cast-iron water main was laid across Galveston Channel, from a connection with the city water mains of Galveston, Tex., to the Government Immigration Station, on the north side of the channel, 1400 ft. distant. The submarine portion of the main was laid in a trench 40 to 100 ft. wide, dredged to a depth of 41 ft. across the entire width of channel, which was then 30 ft. and less in depth. The main was constructed with flexible joints of the ordinary ball-and-socket type, which allows deviation from a straight line of about 12°. Ordinary lead calking was used with yarn packing.

Soon after the pipe line was completed and water turned into the main, leaks began to develop, due partly to the method of laying and to the uneven character of the bottom, which caused such a deflection at each joint that the lead calking squeezed out. Other damage was done to the pipe line by a ship's anchor before the pipe laying had been completed. Efforts made to recalk the leaky joints by the aid of a diver were unsuccessful, because the pipe was found deflected to such an extent that there was no room for calking on two sides of the joint.

*Abstract of article in "Professional Memoirs," Corps of Engineers and Engineer Department at Large, July-August, 1914, pp. 553-559, by N. T. Blackburn, Junior Engineer, Galveston, Tex.

Box Forms for Inclosing Leaky Joints

The method adopted for repairing the leaks was as follows: A wooden box form was placed around each joint, and this form filled with neat portland-cement grout. Each form was supported on three 3-in. pipes, 14 ft. long, driven through holes in the box forms into the underlying clay, so as to form a pile foundation and prevent settlement at the joint.

The box form is shown in detail in the accompanying sketches, Figs. 1, 2 and 3. The box was hinged along one horizontal top edge and opened diagonally. In the top is a 4-in. hole with a pipe flange for connecting a 4-in. pipe extending to the top of the water, as shown in Fig. 3, through which the grout was poured into the box from a barge above.

A chain, fastened to one side of the lower half of the box, helped to close it and held it closed; one link was looped over a hook attached to the upper half of the box, and the hook was screwed up until the form closed tight. On opposite sides of the box, where the water pipe passed through, square holes 18x18 in. were left in order that the box form would close, no matter if the adjoining pipes were at their greatest possible angle, either vertical or horizontal.

Movable diaphragms, each consisting of two pieces, 2x12 in. by 3 ft., with holes cut in the form of an 8-in. semicircle to take one-half the pipe, closed around the pipe, tightly covering it and at the same time entirely closing the 18-in. holes. These false ends or diaphragms were outside of the form and were held in position by iron straps, under which they could move freely against the side of the form.

Three holes, large enough to take a 3-in. pipe, were bored through the top and bottom of the form for the piling. After the pipe piles were driven down through the form flush with its top, ½-in. iron plates were laid over the tops of the piles and bolted to the form, to carry its weight until the cement grout had set around the piles.

Construction Methods

Most of the filling over the water pipe was removed by a 20-in. suction dredge, but for fear of disturbing the pipe, work with the dredge was not carried within 4 ft. of the top of the pipe. The rest of the fill was removed by an 8-in. sand pump, mounted on one of the barges. After dredging, the water was cut off from the main, and air pressure was put on, and the leaks were thus located by air bubbles coming to the surface of the water.

All leaks of any consequence were marked by dropping a weight into the hole blown through the mud over a leak by the escaping air, and carrying a line ashore from the weight. It was not safe to use buoys for marking the leaks, as a buoy was liable to be carried away by ships. All leaks had to be located and marked before repairs were commenced.

After the box form was placed the air pressure had to be taken off the line and kept off until the cement grout in the box form was thoroughly set.

The construction plant consisted of two barges, one carrying a derrick, and the other an 8-in. belt-driven sand pump. The barges were anchored over the leak, and the overlying sand and mud covering was first pumped away. Then to the flange coupling on the box form was connected a 15 ft. length of 4-in. pipe. Three rope lines were fastened to the front of the lower jaw

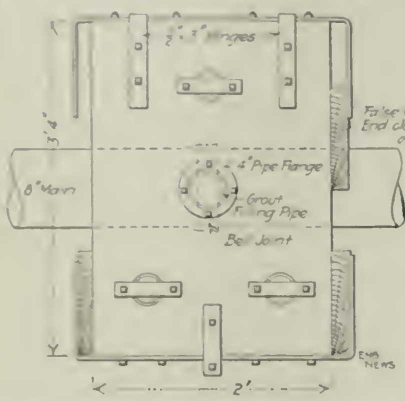


FIG. 1. PLAN OF BOX FORM FOR REPAIRING LEAKY JOINTS

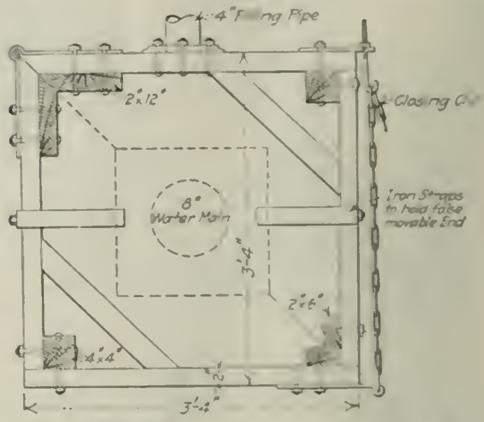

FIG. 2. END ELEVATION THROUGH BOX FORM

of the form, one to the end of the closing chain, and one near each side.

The driver took all three lines down around under the pipe and back up on the barge, where a man was stationed at each line. As the form was lowered away by the derrick with a line from the 4-in. pipe, the men took in on the other three lines. The form was thus guided into place under the pipe. Lowering on the upper half the form closed the box in position.

The piles were then driven flush with the top and the iron straps bolted over them. A water jet was inserted in the box form through the 18-in. square openings, and any mud in the box was driven out and the pipe joint thoroughly washed clean. A piece of raveled, loose rope yarn was tied securely around the leak to keep the cement from entering the pipe joint. The plank diaphragms were then driven into place around the pipe, and the form was ready for the grout.

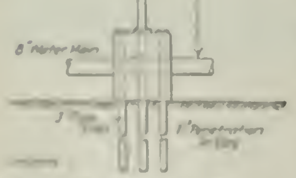

FIG. 3. BOX FORM IN PLACE FOR GROUTING

The grout was mixed with salt water to a consistency that would just pour through the funnel into the 4-in. pipe leading down to the form. It was found necessary to pour it slowly in order to give the grout time to settle. Displaced water went out of the form through the holes around the piling in the top of the form. When the form was filled, the nuts on the bolts in the flange union fastened to the form were taken off and the 4-in. filling pipe removed; and the job was completed. To save time, on the last joint repaired, grout was lowered to the diver in buckets and poured into the form by him.

Where the soft mud and silt was so bad that it could not be kept out of the form, a 4-in. centrifugal pump with a flexible suction end was to clean out the box, after it was in place and closed. The mud was pumped out through the grout filling hole, while a jet alongside stirred it up.

When repairs were completed, the grout was allowed to set a week. About 40 lb. air pressure was then put on the main and kept on for over an hour. During this time only a single air bubble could be seen, and the water meter on the main showed the leaks had been stopped.

Four leaks were repaired and the entire work was executed in about four weeks, including the time of assembling plant, dredging, building box forms, etc. By actual time a box form was lowered and fastened around the pipe in 45 min. To close the end diaphragms of the box form required 50 min. To drive the piles required from 1 to $1\frac{1}{2}$ hr. To mix the grout and fill the form required 1 hr. and 15 min. A good deal of credit was due the diver for the rapidity with which the form was placed. The diver worked without a suit, but simply had a diving helmet over his head. With the proper plant after the water main was cleared, one leak a day could be repaired.

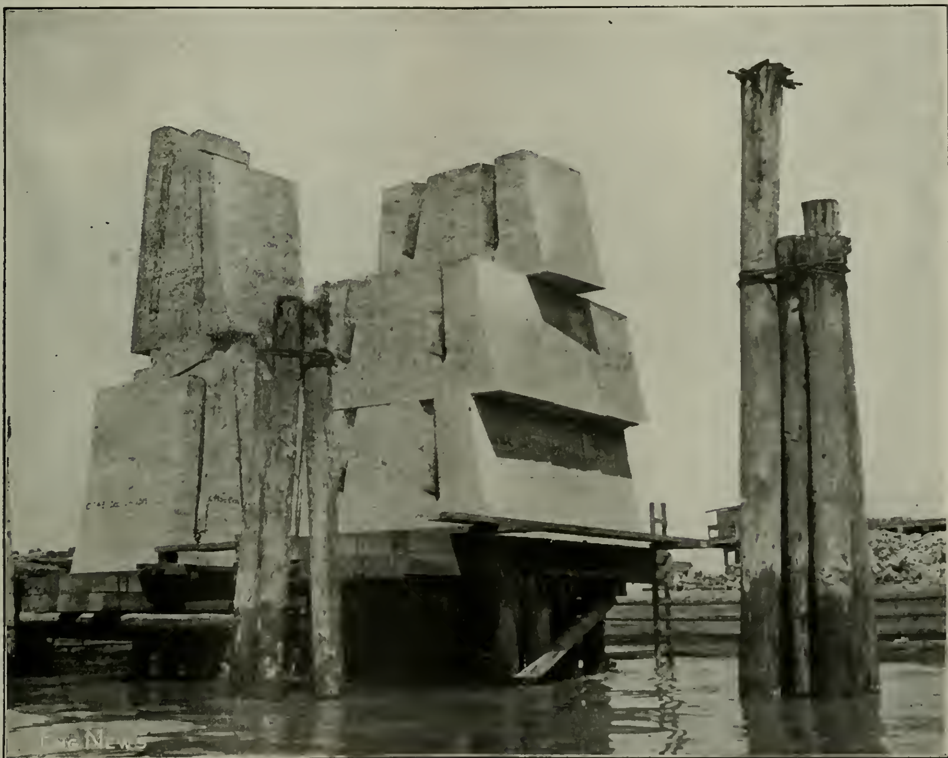
COST DATA

The total cost of repair work, for closing the four leaks, was $2,000. The work was done by the United States Engineer Department, under the direction of Lieut.-Col. C. S. Riche, Corps of Engineers, and the plan of closing leaks was devised, designed and superintended by O. R. Scott, U. S. Inspector. The force consisted of one foreman, one hoisting engineer, six laborers and one driver.

NOTES

A Remarkable Pile Test—The accompanying view shows a test of a group of piles under a load of 220 tons now being carried on by the Department of Docks & Ferries of New York City, under the direction of Chief Engineer Chas. W. Staniford, in the construction of the 46th St. pier of the North River, in the Borough of Manhattan, a description of which appears on p. 212 of this issue. A portion of the pier is to be built in deep water on timber pile footings, which on account of the heavy slit and mud bottom have to be nearly 90 ft. in length. The design calls for carrying the pier proper on 10-ft. spaced piles, but the shed and upper works are to be carried on 20-ft. spacings of columns, footing on pile clusters. This wide spacing requires that each cluster shall have a loading of about 220 tons. The test shown herewith is the second one of two which have been carried on by the department to determine the bearing power of the long pile clusters driven in deep water and very soft mud bottom.

The concrete blocks which are used to load the cluster are the regular quay-wall blocks used by the Department of Docks and Ferries in the construction of the bulkhead walls around New York City. They were floated up to the site and loaded on the structure with the department's 100-ton barge crane. They are to be used in the permanent wall somewhere, when the experiment is finished.



A Remarkable Pile Test

Each cluster consisted of a square of 16 piles, in the first test the piles being driven on about 2-ft. 6-in. centers, and in the second on about 3-ft. 6-in. centers. Each pile is of Eastern pine and is between 85 and 90 ft. long. In the first test, every other pile was lagged on the sides with a double lagging of four 5x6-in. timbers for a distance of 30 ft. up from the bottom of the pile. These four timbers are spaced around the four quarters of the pile circumference and are bolted through, two and two. In the second test every pile in the cluster was lagged.

A marked and continuous settlement was noted in the original test, which has been in progress about seven months, but in the second test, which has been in progress about four months, satisfactory results have so far been obtained under the loading of about 220 tons. It will be some time before the full details of the test are available.

Repairing a Dredge Hull Below the Water Line by Use of an Ice Coffer-dam—The United States dredge "Warroad" was repaired at Kenora, Ont. (Lake of Woods), in 1912 as follows: When the ice had formed about the dredge to a depth of 18 in. a trench was made 20 ft. long, 3 ft. wide and 12 in. deep alongside the dredge. Thereafter each day, when the thermometer had been below zero the night before, 1 in. of ice was cut out of the bottom of the excavation. Days when the thermometer was not higher than +15° F. during the entire day, there were taken out 1½ in. After each day's work a small hole was bored to a depth of 5 in. and dry wooden plugs kept near to plug the holes in case the bit broke through, but it never did. The rate of cutting and the means of insuring a thickness of 5 in. in the bottom of the trench were determined by the custodian of the dredge, as he had no instructions except to get down to the leak. It is probable that he might have gone down somewhat more rapidly, but he was present every day in care of the dredge and there was no occasion to hurry. Parties harvesting ice at that time found that their ponds, left open at night, were frozen about 2 in. during the coldest nights. During the operation, the maximum daily temperatures ranged from +30° to —15° and the minimum from +6° to —47°. Only once was the minimum above zero, and the maximum was below zero for five consecutive days. On Feb. 24—in exactly 30 days—there was a trench 20 ft. long, 3 ft. wide, and 34 in. deep, with 6 in. of ice in the bottom. The thickness of ice in the vicinity was 24 in. So we had gone down 10 in. below the bottom of normal ice; we still had 6 in. under us; and had uncovered the leak 34 in. below water line. The repairs amounted to nothing more than cleaning out a small split

in a plank and caulking it. [Lieut.-Col. Chas. L. Potter, Corps of Engineers, U. S. A., in "An Ice Coffer-dam," Professional Memoirs, Corps of Engineers, U. S. A., May-June, 1914, p. 149.]

Computation of Lot Lines on Curved Streets—A. M. Haynes, of 314 So. Washington St., Denver, Colo., is worried lest the method of computing lot lines described by P. H. Skinner in "Engineering News" of June 25, p. 1241, will mislead surveyors. He writes to Mr. Skinner as follows:

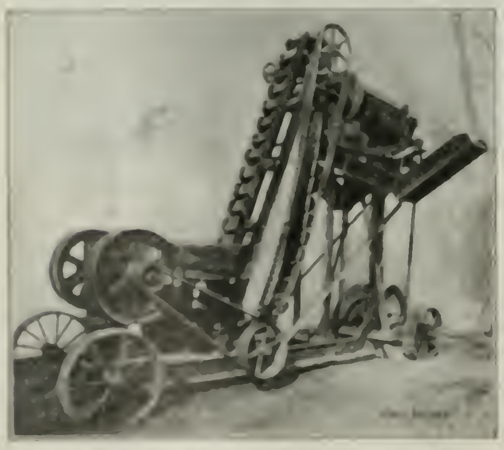
I have been to much trouble making tables for the work you describe. It is the same method as invented by Shunk and copied by many authors in the past 30 years. I made a new definition for Degree of Curve and made the work exact. I find the degree of your curve is 11 175°. Your x is half the long chord, and y is R — versed sin of double your angle A. My tables give exactly the same figures that you have for frontage, and I do not bother with the old-fashioned Sin, Cos, etc. Should you not send this to the "Engineering News" to repair damages? A lot of poor transmitmen will lose their jobs trying to follow you.

To this letter Mr. Skinner replies as follows:

To cover the remote possibility that others may have fallen into the same misapprehension that has brought forth the letter from Mr. Haynes, it may be said that the method of computing curves, described in "Engineering News" of June 25, is intended for use only where logs or a calculating machine are available. Such an arrangement of work has been found to shorten the computations greatly in the office, but no claims are made for it as a field method.

A Wagon-Loading Machine for dry brick clay is employed by the Hydraulic-Press Brick Co., of St. Louis, Mo., in gathering the clay for its plant. Special plows hauled by traction engines turn up the top of the field to a depth of $1\frac{1}{2}$ in., the teeth of the plow being so set that each turns up a strip about $4\times1\frac{1}{2}$ in. This strip curls over and breaks into pieces 4 to 8 in. long as it falls from the plow. The entire field is plowed in this way and left to dry for 12 to 24 hours, according to the weather. The wagon loader has a four-wheeled wagon bed, surmounted by an enclosed vertical frame or tower within which works a vertical bucket conveyor having long buckets. The lower end of the conveyor comes close to the ground and just in front of it is an apron which gathers up the clay so that it is within reach of the buckets. At the top, the buckets dump their contents into an inclined chute projecting from the side of the tower and discharging the clay into wagons which are driven alongside the machine as it travels across the field. The elevating conveyor is driven by a sprocket chain from one of the rear wheels, and the machine is hauled by a team of six mules. The plows and wagon loaders are of the company's design and are built in its own shops.

A Dinkey Stone-Crushing and Screening Outfit is illustrated herewith. The whole plant mounted on a four-wheel steel truck weighs only about four tons and can be moved from place to place by a pair of horses. The outfit includes a Fort Wayne No. F 2 jaw crusher, which has provision on for three different targets, for crushing coarse, medium and fine; a belt-driven steel chain bucket conveyor, a revolving cylindrical screen, with dust jackets if desired, and a dumping or loading chute. The jaw opening for coarse and medium crushing is 8x12 in. and for fine crushing 5x12 in. The elevator is 12 ft. 6 in. long. The revolving screen is about 3 ft. long and 2 ft. 6 in. in diameter. The mounting is a steel



A Small Portable Crushing and Screening Plant

frame of I-beam construction with heavy steel wheels and axles. The wheels have broad tires, and the hubs are provided with lubricating cups. Motive power for operating the crusher, elevator and screen may be furnished by an 8-hp. gasoline engine, which, however, is not part of the outfit as shown. The speed of the eccentric shaft is designed to be 285 r.p.m. and the belt drive should be 16 to 18 ft. long. The outfit described is made by the Good Roads Machinery Co., Kennett Square, Penn.

Nailed Wedge-Shoes for Shores in Floor Centering—Placing concrete centering accurately and economically is an engineering problem. Floor centering, when ready for concrete, should be level, and the accompanying illustration shows how Wells Bros., Chicago contractors, start to get level points before placing shores for floor centering.

On the finished concrete surface of the floor over which they are working, and which is brought to a true surface with the top finished, 1-in. boards are laid, on which are

Setting Wedge-Shoes for Floor Centering to a Uniform Elevation with Level and Rod

placed wedges, cut from ordinary 2x4-in. stuff, to serve as shoes for the vertical shores.

To establish levels for each panel a handy man goes ahead with wedges, and at four well distributed points for each panel he nails in place the bottom half of a pair of ordinary 2x4 wedges, fastening it firmly to the 1-in. sills. A wye level is set up at a convenient point on the floor, and a definite uniform elevation is established by adjusting the pairs of wedges to a known level established by the instrument. Then the top half of the wedge is nailed in place, determining accurately at 4 points in each panel a standard elevation.

New Types of Automatic Water-Stage Registers have been put on the market by W. & L. E. Gurley, Troy, N. Y. These include an entirely new device which makes a printed record of the water height at intervals of 15 or 30 min. This register is built and installed like the regulation gage-curve recording registers, but instead of a pen point moving over a wide roll of paper, a narrow ribbon of paper passes continuously under a time stamp. The type wheels for printing the height records are moved automatically by the rise and fall of the copper float in the gage well. The motive power for operating the register is a weight-driven clock, the weight of which descends at the rate of $1\frac{1}{2}$ in. in 24 hr. The ribbon record is $1\frac{1}{4}$ in. wide, and the record for 24 hr. is 96 impressions within a space of 2 ft. The range of the machine is 16.66 ft.

The same manufacturers have also improved their standard graphic registers so that they will make two and seven-day records, of the curve kind.

Lessons from the Lowell Experiments on Well-Water Treatment

The experiments on driven-well waters at Lowell, Mass., described in our issue of July 9 and in our present issue, are encouraging not only for Lowell but for other cities as well. At the same time they illustrate anew the difficulties that may be encountered with well waters, even where such supplies do not seriously diminish in quantity as well as in quality after a few years' use. They also show how each well water may be a law to itself as regards needed methods of treatment.

Twenty years ago Lowell began to secure a water-supply from driven wells. The water from the first wells sunk appeared at first to be satisfactory in quality, but not being sufficient in quantity, more wells were sunk at a different site. After a few years' use, it was shown that an excessive amount of carbonic acid in the water from the first wells attacked lead service pipes and caused lead poisoning throughout the city. The other wells were therefore added to and the first wells abandoned, except for summer-peak use. Although several extensions to the new well system were made, the water from it gave more and more trouble from turbidity and color. This was at first attributed wholly to iron in the water, but it has been shown recently that the trouble was due to manganese as well as iron.

Hygienically, the Lowell well water was excellent, as indicated by the typhoid record. It was therefore decided to find out whether the iron and manganese could be removed from the one well system and the carbonic acid from the other.

The experiments emphasize afresh that each well water is a law unto itself when it comes to removing or neutralizing unsatisfactory mineral contents, and that a testing or experimental plant, in the hands of trained men, is often needed to find the law and the best means of applying it in daily practice.

So far as iron is concerned, some of the many conditions governing its removal are thus stated in F. A. Barbour's report on his recent Lowell studies:

> Iron, which is found in the form of ferrous hydrate, can be readily oxidized, and if there are no interfering substances, such as manganese, carbon dioxide, or organic matter, which hold the iron in semisolution, or in a colloidal condition, it can be precipitated and removed by aëration and sand filters. In some waters, however, excessive aëration is possible, and a retention of a certain portion of the carbon dioxide is necessary to prevent the organic matter from interfering with the precipitation of the iron. Also, it has been found that manganese interferes, and the removal of the last traces of iron, if the necessary conditions are not provided for the coincident removal of the manganese is impossible. It therefore follows that, while the deferrization of some waters involves simple aëration and sand filtration, others require more highly developed preliminary treatment by passage through coarse filters, operating either as tricklers or contact beds.

Apropos of the last clause of the last sentence, it may be noted that coke prefilters at Lowell, it was found, should be operated as contact beds rather than as trickling filters for the removal of iron and manganese.

The diversity of well waters from sources near together is illustrated by Lowell experiences. One series of wells yields water high in iron and manganese and another gives a water low in iron but with so much carbonic acid that the water attacks metal service pipes. Close by the group of wells last mentioned, with low iron content, is a third group, for some time unused, with an iron content so high as to promise trouble with the increase of iron that so often follows use.

Considering now the removal of carbonic acid from the Lowell wells, it is worthy of note that before the experiments were begun, it was supposed that a fraction of a grain of lime per gallon of water would decarbonate this water. Instead, it was found that 1½ grains per gal. would be required, which would have added an intolerable hardness to the water. Fortunately, the experiments showed, the carbonic acid can be easily removed from this water by aëration by means of fine-spray nozzles under light pressure.

As we said at the start, the Lowell experiments are encouraging to all who have certain ground-water problems to solve. But it must not be overlooked, as we have tried to make clear, that each ground water is so much a law unto itself as to make it unwise to adopt any special mode of treatment until local experiments, or at least expert advice based on laboratory tests, indicate that the proposed treatment will successfully and most economically meet the conditions of that particular water.

Legislating the Massachusetts State Board of Health out of Office

Whether considered as a sacrifice to politics or to progress, the abolition of the time-honored and justly renowned State Board of Health of Massachusetts will come as a shock to sanitarians and public-health workers the world over. We sincerely hope that the State Department of Health which takes the place of the Board will make as enviable a record for itself and do as much for public health and sanitary progress within and outside of Massachusetts as did the State Board of Health.

Unfortunately, the new Department starts with a handicap—or a bunch of handicaps. First of all, the Governor and his political associates are under suspicion of having successfully promoted a reorganization of the health administration of the State in the name of governmental progress but with political expediency as the real object. This suspicion may be lived down by a judicious series of appointments to the positions of Commissioner of Health, Public Health Councillors, Directors of Divisions and District Health Officers. But even if this suspicion be lived down instead of being justified by the building up of a part of a state political machine, the fact will remain that the new Department of Health of Massachusetts will be of a mongrel administrative type.

The Commissioner of Health, nominally the chief exe-

[illegible] health officer of Massachusetts, is really under the control of the Governor and Council of the State on the one hand, since they confirm all appointments made by the Commissioner, while on the other hand, he is dependent on the Public Health Council (1) for the approval of the appointment of directors of divisions and of district health officers before these appointments go to the Governor and Council (a sort of State Cabinet) for confirmation; and (2) is also dependent upon the Public Health Council for the enactment of department rules and regulations. In addition, the Public Health Council acts as a Board of Appeal, presumably from orders issued by the Commissioner, although that is not clear. The Commissioner reports to the Public Health Council and the latter to the Legislature, through the Council.

Instead of an out-and-out single-headed Department of Health, Massachusetts will have a combination of the commissioner and the board plan, with neither supreme, and with Commissioner, Public Health Council, Directors of Divisions and the eight (geographical) District Health Officers all creatures of the Governor.

To make matters worse, the members of the Public Health Council are to be paid $10 a day and traveling expenses, which is just enough to attract place-seekers but too little to compensate men of training and ability, who would rather serve gratuitously than be paid inadequately for their time.

The long and short of the matter is that what was heralded at the outset as a radical reorganization of the state health service of Massachusetts, with a single independent Commissioner, quick and powerful in action, turns out to be little but the substitution of a Council for a Board and a Commissioner for a secretary, with neither in supreme command, and with a nebulous area of duties, powers and relationships in place of sharply delimited fields of responsibility and power.

Whether the old board plan or the newer single-commissioner plan is the best for Massachusetts or for any other State, we are not discussing. That a jumble of the two should be avoided seems to need no argument.

We are not so rash as to say that even under the abortive act which goes into effect on Aug. 7 (see our issue of July 16), men of training, ability and devotion cannot sustain the high standards of the Massachusetts State Board of Health which so many of us have long admired and rejoiced to honor. Men like Mills and Walcott, Woodruff and Harrington, Stearns and Noyes, Drown and Sedgwick, Hazen and Fuller, to name only some of the former members, secretaries, engineers, chemists and biologists who have helped make the Board known the world over, would rise above any petty obstacles incident to a badly muddled piece of legislation. But, and there's the rub, they would not stoop to become parties to the political expediencies which the present act seems on its face to have been drafted or influenced to serve.

If the new appointments are not already made before these words are printed, a few weeks at most will serve to show in large measure how far the Governor of Massachusetts, in advocating a reorganization of the State health service, was actuated by a desire to give the State what he conceived to be a more efficient health administration and how far his ruling motive was to build up a more efficient political machine. If, as we hope, the health service is the thing at heart able men can doubtless be found to carry on the work so well performed in the past and the next legislature can perhaps be induced to remedy the obvious defects in the new health act, as well as the weaknesses which a few months will bring into prominence.

A National Water Law

The need of national legislation on the matter of river regulation and control is agreed upon by everyone familiar with the facts. That, however, is about the only point on which agreement exists. One group is concentrating all its energies to have a national law passed that will facilitate the development of unused water powers by private enterprise. Another group is concentrating all its influence to secure the enactment of legislation under which the federal treasury can be tapped to aid in the construction of levees for the Mississippi and its tributaries. Still another group is infatuated with the idea that the Newlands bill, with its fantastic plan for concentrating all authority over the uses of water for every purpose throughout the length and breadth of the United States in a federal bureau at Washington, is the way to salvation and is working diligently for the success of that scheme.

It may be freely admitted that many of the advocates of the Newlands scheme are actuated by high ideals; but as we showed in an analysis of the Newlands bill in these columns a year or so ago, the Newlands bill as a measure of practical government administration is far too vast and unwieldy and complicated to possibly be successful.

The trouble with all these schemes heretofore presented is that they have been drafted to serve some particular interest and generally with entire ignorance of the other interests involved. Under these circumstances, the work of the special committee of the American Society of Civil Engineers appointed to prepare a national water law with special reference to the Federal control of interstate waters is particularly timely. This committee has just sent out a circular letter of inquiry asking for information where controversies exist over the use of interstate waters, and its aim evidently is to obtain first of all a large amount of facts on which to base its general conclusions. Any engineer desiring to aid the committee in this work by giving information as to controversies in which the control of interstate waters is involved can doubtless obtain copies of the circular letter of inquiry by addressing the Chairman of the Committee, Frederick H. Newell, Chief of the U. S. Reclamation Service, Washington, D. C.

Cellular Sheet-Pile Coffer-Dams; The Maine Coffer-Dam and Its Lessons

The very remarkable coffer-dam now under construction at the foot of 46th St. on the North River at New York City and described in detail elsewhere in this issue is worth the closest attention of the constructing engineer, especially the man engaged in any kind of marine construction. So far as we know, it is to be under a greater head, when completely unwatered, than any other coffer-dam ever successfully completed and at the same time its extreme length increases considerably the liability of localized failure.

A study of its design inevitably calls to mind the famous coffer-dam around the wreck of the "Maine" in Havana harbor, so that a brief history of the behavior of that dam and a comparison of it and the North River dam should be in order.

It will be remembered that the "Maine" coffer-dam was designed to be a series of circular cells, each 50 ft. in diameter, tangentially interlocked to form a closed ellipse about 400 ft. in its major and 170 ft. in its minor axis, with each cell made up of interlocking steel sheet piles and filled to the top with mud taken from the harbor. It was sunk in a depth of 35 ft. of water, with a mud bottom about 120 ft. above rock. The piles were 70 ft. in length, made up of two spliced sections to each unit, and they penetrated about 10 ft. of a dense mud or clay stratum. While precedents for such a design under such adverse conditions of head and material were entirely lacking when the "Maine" coffer-dam was planned by the U. S. Army Engineers, it was the hope that the individual cylinders would act as rigid columns and, while it was not counted upon, that there would be a certain amount of rigidity given the whole structure by the elliptical shape, in other words that some arch action from cylinder to cylinder would take place.

How far these original hopes were realized is shown in the final report of the "Maine" Board, which was published as a government document early this year. From that report, which is incidentally a most valuable engineering treatise, it will be learned that the cylinders were anything but rigid, that they commenced to bulge and distort and even to break under the fill of hydraulically placed mud from the harbor, that the linear distortion of the coffer-dam itself under the low heads of the early unwatering became so great as to require what ENGINEERING NEWS predicted would be necessary, viz., the dumping of riprap against the inside of the coffer-dam and further to require the shifting of the fill inside the cylinders so as to form in effect a continuation of the riprap slope from the inside bottom of the dam up through the cylinder. Finally, before the dam could be completely unwatered, a number of heavy braces had to be set between the cylinders and the wreckage of the "Maine" and one continuous brace had to be placed across the dam.

This final structure was successful in its purpose; the "Maine" was examined, dissected, floated and removed to the ocean bottom outside the harbor, without damage to life, limb or property and the site was restored to the condition it was in before that fateful February of 1898. But instead of an originally estimated $300,000, the total expenditure for the work was $785,774.83 and the final coffer-dam was far different from the original project.

This pioneer work done at Havana served admirably to instruct the engineers of the New York dock department in the things to avoid in the North River coffer-dam. In two respects, the conditions at the two sites were quite similar. Both dams had to be footed in a mud bottom so far above the bedrock as to forbid reaching it with the piles, and both were to hold back very high heads of water, that at Havana averaging 40 ft., with pockets inside the dam reaching 50 ft. below the water level while it is expected the average excavation in the North River will be 44 ft. below low water with the inner toe of the dam about 20 ft. lower. Here the similarity ends, for the Havana dam was a comparatively small closed curve while that at New York is a very long nearly straight line, precluding the possibility of cross-bracing. The similarity is sufficient, however, to make the lesson of the earlier dam useful in the building of the later, particularly in regard to the assumption of rigidity in the filled cells.

In their report, the Army Engineers state that in their opinion the rigidity of the cylinders, and therefore the correctness of the original design, would have been assured had the filling of the cells been made with some solid, dry clay instead of the harbor mud, heavy with water because of its placing by a suction dredge. However, the New York dock engineers apparently are not entirely convinced of the truth of this conclusion, for they have designed a dam, which, while it possesses a family resemblance to its predecessor in Cuba, is in realty a radically different structure, only remotely depending on the cylinder rigidity. It is in effect, a dam of riprap which in turn is retained by a series of mud-filled sheet-pile cells. The inherent rigidity of the cells is assumed to be sufficient only to uphold the cells themselves and to withstand the limited pressure of the riprap backing, which is offset somewhat by the outshore mud backing.

Manifestly, the final expensive efforts to maintain the Havana cylinders as rigid columns will not trouble the New York engineers, but on the other hand, they will be put to an equally serious concern in preserving the balance of load against the cellular core during the progressive removal and placing of the mud and stone fills on either side of the dam. So far the only trouble experienced has been in severe straining, and in two cases rupture of the pile interlock due to the excessive pressure of the interior fill; but when unwatering commences, or even before that when the side loads are placed, the behavior of the dam will be of the greatest interest. Holding back 50 ft. of water across a 800-ft. opening and with a mud fill as a base, is a colossal engineering feat.

The Interstate Commerce Commission's Indictment of the New Haven Railroad Administration

The scathing report of the Interstate Commerce Commission on the financial mismanagement of the New York, New Haven & Hartford R.R., made public last week, is a document whose importance can hardly be overestimated. To a considerable extent, the facts which are set forth by the Commission in its arraignment of the New Haven directors have been known for some time by the well posted in financial circles. The Commission's report, however, now collects all this information and presents it in a most forceful manner, the whole constituting probably the most damning indictment of railway mismanagement on a large scale that has ever been made in this country.

The most important feature of the New Haven wreck is not merely the vast amounts of money which have disappeared like dew before the sun. It is the character of the men and the firms and the companies which were concerned in and were responsible for the wreck. It is well known, of course, that the history of American railroading is full of instances of crooked financing. Since the

very early days of the railway era, there have been railway promoters and railway wreckers, whose methods of doing business have been on a par with those of the green-goods vender, the confidence man, and the vender of wild-cat mine prospects. There always have been pirates on the financial seas; and when they came into control of a property, wise investors knew that it was time to sell out.

But what had the old, conservative New York, New Haven & Hartford R.R. Co. to do with business methods of such a sort? Year after year, and decade after decade, the company went on its way, paying its regular 10% dividends and investing large amounts in excess of these dividends in the improvement of its property. All through New England, stock of the New York, New Haven & Hartford had a reputation equal to that of first-class state or municipal bonds. Men and women invested their money in New Haven stock and thought it was as safe as the savings bank. The directors and officers of the company were largely New England men of good reputation for honesty and conservatism. The great banking firms identified with the property had a reputation for turning everything they touched into gold which even King Midas might have envied. Is it any wonder that when, following the advent of Mr. Mellen to the presidency, the company embarked on a policy of expansion and filled the newspapers with glowing accounts of its great plans for development and extension, New England investors were ready to pour out millions to buy additional New Haven stock and bonds as fast as they were offered.

There seems to be, even now, a considerable degree of misunderstanding as to the real crime of which those who have controlled the New Haven R.R. Co. have been guilty. It is not the traveling and shipping public that has suffered materially. The New Haven R.R. system has on the whole rendered good service and its rates have been on the whole reasonable. The crime committed has been against the owners of the property, those who purchased in good faith its stock and its bonds and to whom the directors were responsible as trustees.

The Interstate Commerce Commission estimates that the losses to the New Haven stockholders through the dissipation of the company's assets during the past ten years amount to $60,000,000 to $90,000,000. The proceeds of the stock and bonds which have been issued by the New Haven Co. during the last ten years have been used to buy properties at prices far in excess of their true value. Over $30,000,000 was invested in the Westchester enterprise. More than this amount was expended in buying street lighting and electric-railway properties in Connecticut and much more in the street railway properties in Rhode Island. Many millions have been lost in the foolish attempt to control the Boston & Maine Co.

The only defense made for these purchases, and in fact the only possible defense, is that those who were responsible for them honestly believed that it was for the interest of the company to purchase these properties at the prices paid in view of their future value to the company. It requires a large amount of credulity for one to believe this defense. The financial history of the properties acquired and the way they were acquired, the enormous sums paid to go-betweens, the great amount paid for "convincing" public opinion, for manipulation of state legislatures—all of these and many other things covered in the report of the Commission and the knowledge of the circumstances and conditions under which the New Haven wrecking operations were carried on, all point to the inevitable conclusion that those of the New Haven directorate who were responsible for these huge exploits in high finance were not by any means ignoramuses, but were in fact the hard-headed, shrewd bankers and lawyers and financiers that they were held to be by general reputation.

That somebody profited, and profited enormously, by those exploits in high finance is beyond dispute. The $60,000,000 to $90,000,000 which have been lost by investors in New Haven securities have not been destroyed; they have simply been transferred to the pocket of someone else. It is possible that the courts may be able to unravel some of the financial tangles and compel restitution of some small part of the losses the New Haven stockholders have sustained; but it is at best only a possibility. The statute of limitations and the work of the shrewd lawyers who covered up the processes of high finance, combine to effectually hamper any effort to compel restitution.

It is important that the situation should be clearly understood, however, since there appears to be an attempt to shift the blame from the shoulders of those responsible. It is claimed, for example, that it was State and Federal interference with railway operations in New England that caused the losses of the New Haven stockholders.

For a direct and complete answer to this statement, one has only to take the gross and net earnings of the New Haven Ry. system itself at the present time. In the 11 months ending May 31, 1914, the New York, New Haven & Hartford R.R. Co. earned $60,927,000 gross and $13,291,000 net. These figures put out by the company itself, show conclusively that the railway still earns enormous profits. It is the other enterprises which the New Haven directors foolishly and wickedly loaded upon the railway company, whose deficits and fixed charges absorb the profits that the railway company earns.

It is claimed, however, by those who would defend the New Haven management, that during all the time that the New Haven has been carrying on these exploits in high finance the Federal and State governments have had full authority to control operations; and that if these things were contrary to law and against public policy, the government should have stopped them.

This is indeed pleading the baby act with a vengeance. As well might the burglar arraigned before the court say that he was not responsible for the theft he had committed since the city police department and the private watchman of the bank maintained an organization to prevent such depredation! It seems well nigh incredible that men with a fair degree of intelligence should put forth such a plea and expect it to be accepted at face value.

Another aspect of the New Haven matter on which altogether too much emphasis is laid is the idea that the chief offense of the directors was in attempting to create a monopoly in New England transportation. It is even on the program that a Federal suit is to be brought against the company under the Sherman law.

But as a matter of fact, there has been, for nearly two decades, no important amount of competition in New England. The old New England Ry., the only competing railway line between New York and Boston, was absorbed by the New Haven Co. before Mr. Mellen's day.

The much-discussed absorption of the Boston & Maine system by the New Haven Co. did not have, to any important extent, the elimination of competition as its object, for at very few points do the two systems compete with each other.

It was indeed a foolish piece of business for the New Haven to purchase control of the Boston & Maine at the price which was paid; but so far as the traveling and shipping public in Boston & Maine territory is concerned, the only question is whether the old or the new management gives more efficient and economical service.

Even the purchase of the Connecticut and Rhode Island trolley lines cannot be considered to have been in any large degree for the purpose of creating monopoly, although when originally built, these lines did take over traffic which had previously been carried on local steam-railway trains. But the field of the electric-trolley railway and of the steam railway is now well established; each handles the traffic to which it is best suited, and no steam-railway manager with any claims to good judgment would dream of purchasing trolley lines simply to stop their competing with his steam-railway trains.

There is, of course, no doubt that the managers of the New Haven system did attempt to create a monopoly of all rail and water transportation in New England and to a large degree succeeded; but the absolute power of State and Federal commissions to control both rates and service rendered made it impossible for any such combination to reap monopolistic profits. The existence and operation of this power of government control during the years while the New Haven monopoly was in process of creation were perfectly well known to Mr. Mellen and his associates. They knew perfectly well that any attempt to advance rates because of the absence of competition would meet defeat. They knew perfectly well that however much they might perfect their monopoly, the rates they could charge and the service they would be obliged to render would be under public control—a control which has grown and is bound to grow more strict and certain with each succeeding year.

The most important results of the New Haven episode is likely to be its effect on public opinion. It has done more to injure railway credit and make it difficult to sell railway bonds and stocks, both here and abroad, than any similar event in the railway financial world for 25 years. It is today, without doubt, having a powerful influence at Washington upon the appeal for permission to increase freight rates, upon the current acute controversy between the Western railways and their engineers and firemen over a radical increase in wages, upon pending legislation in Congress to establish public control of railway security issues. Those who argue against the increase in freight rates say, "of what avail to give these companies larger revenue when it only gives their banker directors a larger surplus fund to play with in Wall Street. Railway employees, when told that the railway companies cannot afford to grant the increase in wages asked, listen with incredulity and declare that when railways can invest millions of money in all sorts of outside enterprises, they must have money enough to pay higher wages. In the debate upon Federal control of stock and bond issues, it is argued that the officers charged with such control would be governed by political influence and even if honest would be ignorant of the details of corporation finance. Those who favor such control, however, answer this argument by merely pointing to that tangled web of iniquity woven by the New Haven management and say, "could anything be worse than that?"

Still further, no one who keeps in touch with the state of public opinion can doubt that the New Haven wreck has made converts by thousands and hundreds of thousands to the government ownership of railways. That clause which the Massachusetts legislature insisted should be tacked on to every certificate of Boston & Maine stocks taken over by the New Haven, that the State of Massachusetts can at any time purchase the stock at an appraised valuation, is merely a straw showing which way the wind is blowing.

There is at least one constructive and useful suggestion which ought to result from the New Haven wreck, and that is the necessity of a sweeping reform in the method of control of our great public corporations.

In the New Haven wreck, public attention is fixed upon the directors and all the talk is of suits against them to compel restriction. In Washington nowadays the tendency is to treat every director of a great corporation as a man under suspicion. The statesmen (or alleged statesmen) at the Capital are busying themselves with the framing of laws to prohibit interlocking directorates and to find out how to prevent this or that or the other class of men from being elected as directors of the public-service corporations. Not a word is heard as to the solution of the most difficult problem, that of finding men of requisite ability and trustworthiness who are willing to serve as directors of our great corporations and assume the responsibility that should rightly be theirs.

In this very case of the New Haven Company, probably not one in ten of its Board of Directors really knew enough about the affairs of the corporation to fully realize what was going on. Practically all of the directors had their own business and personal affairs to attend to. Membership on the Board of Directors required them to attend, if convenient, a directors' meeting possibly once a fortnight or once a month, at which they voted on such affairs as the three or four leaders in the directorate chose to lay before them.

Such a system of control might perhaps pass muster with the men and the methods of 25 years ago; but it is an absolute failure under the conditions existing today. The board of directors of a great railway or industrial corporation should be made up of men willing and able to devote enough time to the work so that they can fully inform themselves on all the large questions of policy which the board of directors alone should decide. Such directors should be paid enough to command the services of the ablest men, who will regard the office as a public trust instead of considering, as has been too often the case in the past, that membership in a directorate, since it brought no direct compensation of consequence, justified one in making such profits as opportunity permitted from private operations made possible by the knowledge he gained as a director.

With a board of directors paid to devote time to their work, it would be possible to hold them to strict personal and financial responsibility for their acts. If such responsibility is enforced under the present system, however, it simply means that we must be content with a set of men for directors of our public corporations who will be financially irresponsible, since no others could afford to accept such positions.

Letters to the Editor

The Earnings of Technical Graduates

Sir—Under the caption "The Potential Value of Our Engineering Graduates," ENGINEERING NEWS of June 25, prints an extract from the address of Prof. Harold B. Smith, at Clarkson College of Technology, Potsdam, N. Y., in which the Professor says, "the technically trained graduate of our engineering colleges earns annually, on an average, at least $3000."

The average annual earnings of technical graduates who are employed in the bridge and structural engineering departments of the various railroads, bridge and structural shops, engineers and architects are less than one-half of $3000. Further, it is generally understood that those engaged in the bridge and structural line receive a somewhat higher wage than those in the other engineering branches.

Prof. Smith may, by some sort of legerdemain, satisfy his own mind that his is not a gratuitous assertion, but this Clarkson Class of embryo engineers, who received this last injection of university optimism, "bunk," will soon learn their *actual* value as money-getters, and it will be a sad awakening.

HARRY J. BUCH.

A Defense of the Pittsburgh Flood Commission

Sir—In the *Proceedings* of the Engineers' Society of Western Pennsylvania, Vol. 30, No. 2, Mar. 11, 1914, the paper read by Sir William Willcocks on "How the Ancients Would Have Controlled the Mississippi and Its Tributaries," contains certain references to the report of the Flood Commission of Pittsburgh, Penn.

The privilege of an engineer to discuss the work and opinions of his professional brethren is well known and this may even become a duty, if differing profoundly upon important public policies, affecting the safety, health and general welfare of the people. There is, however, a duty, fully as grave and customarily imposed, and that is that one shall completely inform himself before criticising the position and statements of others. This is particularly true and the duty is all the more important when the critic occupies a world-wide position of renown and international standing in the profession.

As to this address delivered at the invitation of the Engineers' Society, certain statements appear to attack the methods and findings of the engineering work of the Pittsburgh Flood Commission, the members of the Engineering Committee believe it a duty to the profession, as well as to their associates on the Commission, to answer the exceptional criticisms contained therein. The remarks of the author evidently were not based upon an accurate reading of the Flood Commission report. Had he carefully read and considered such report or obtained correct information thereto, it is believed that his views upon the matter of flood control, as applied to our local rivers, would have been materially modified.

(1) The author undertakes to impress his readers that his opinions were based upon personal observations and at the same time to lodge a charge of incomplete investigation against those who have been responsible for the Flood Commission Report. For instance, he says on p. 128:

> I never saw such bad looking stuff for reservoirs, and I found that no one had bored down one foot to see.

As a matter of fact, the author never visited a single reservoir site and fails to show the source of information, hearsay or otherwise, upon which he was relying for his extravagant statements. Upon the other hand, members of the Engineering Committee of the Pittsburgh Flood Commission visited the site of each proposed dam and satisfied themselves fully as to the presence of natural rock formation.

(2) Again on p. 128, the author says:

> And your condition is such that if you had a high flood and a reservoir with 150 ft. head on the hills above you, and it happened to breach and come on top of the flood, all of the disasters you know of today would be but child's play. And if you had two in the same valley and the upper one burst and came down on the lower one, and the two came together, you might open the early chapters of Genesis and begin reading about Noah's flood to comfort you.

The purpose of the author's pleading is not clear. If he is adverse to dams of 150 ft. or more in height, because these are dangerous, we respectfully call attention to the fact that the highest dam proposed by the Commission is 113 ft. in height and the average of the seventeen dams proposed is 93 ft. However, we further note that there are several dams in this country of more than 200 ft. in height. Height simply requires adequate design and strength.

(3) Upon p. 127 of the paper, the following statement occurs:

> This horizontal sandstone you have here and shale in alternating strata is considered the worst foundation for reservoirs of anything in the world. More accidents to big reservoirs have happened on it than any other. If the strata are inclined at a steep angle and you build your dam on it, it rests on the hard particles and the weak strata are more or less ignored.

As the author very shrewdly abstains from giving definite information as to who holds these absurd opinions as to our local geological conditions and as we are addressing those who have knowledge of these matters, comment is unnecessary.

(4) Upon p. 128, the author states:

> In your book you show that you spent money on many things, but not one penny to show what your foundations are, and all the rest of it is worth nothing until you are sure of your foundations. You ought to spend some money for drills and take two of the nearest sites and expose the foundation and see if you can build a dam there. If you find real good foundation your difficulties will be at an end.

Engineers of ability and experience engaged upon a preliminary study and general design, judge by the surrounding outcropping rock, which indicates geological

conditions. Thus the feasibility of location is determined and customary allowance made in estimates of costs for depths of foundations. Later drillings will determine actual design and depth.

Without undertaking to give detail answer to this criticism and show how the money was spent, all of which is stated in the report thus mentioned, the engineers of the Flood Commission, after personal inspection of the sites, considered that it was unnecessary to spend any money for borings for the purpose of their preliminary report. But it goes without saying that before actual sites would be determined and building begun, such borings would, of course, be made by those responsible for the design and construction.

(5) Upon p. 127, it is further stated:

In a recent book which you have written on this reservoir question I see that the quantity of water you consider necessary to impound in these reservoirs seems to be in excess of what you need. In all the calculations it has been assumed that when the river rises, its discharge increases up to its maximum stage. . . . As in all these estimates, you have allowed for an increasing discharge and not reduced by half for the falling gage, a much smaller quantity of water than you have assumed would, I think, suffice to shelter you from these hours of high flood which produce all the worry.

This appears to be a criticism of the use, by the Flood Commission Engineers in their report, of a greater factor of safety than the author thinks necessary. It may be stated that the hydraulic measurements, upon which the quantities were determined, were based upon the careful methods of the United States Geological Survey and of the Pennsylvania Water Supply Commission and many of the stations were operated in coöperation. Full and complete allowances were made in the rating curves, notwithstanding the above quoted comment, for the fact that river velocities are not the same upon rising and falling stages. This statement can be verified by reference to the rating diagrams in the report.

(6) The weakness of the author's paper and of the apparent criticisms of the Flood Commission's report are due to two facts: The opinions expressed in the report were based upon five years' study by engineers who possessed full knowledge of local circumstances and who therefore do know, whereas the remarks of the author emanated from a necessary cursory and hasty examination of the subject and conditions.

(7) The Engineers of the Pittsburgh Flood Commission have the highest appreciation of the professional and ethical responsibility of opinions upon such a question as flood control and regret that so eminent an engineer should undertake to speak to the world upon such an important subject without fully informing himself as to the data from which he draws his conclusions.

Brick-Pavement Repairs

Sir—I have read with much interest your editorial comments in ENGINEERING NEWS, July 2, 1914, on "The Neglect of Brick Pavements," and I fully agree that from whatever cause a repair is needed in any kind of a road, including a brick road, it should have immediate and prompt attention. But I must take exception to one or two statements made in the editorial, also to the form of remedy suggested.

First, your statement:

On many miles of brick paved roadways in Cuyahoga County, Ohio, which have been laid within a comparatively short time and are good examples of first-class construction, the only defect noticed is longitudinal cracks extending along or near the center of the roadway.

The objection to this statement lies in the fact that they "are good examples of *first-class construction.*"

Many of your readers will recollect the paper read before the American Highway Association in Detroit last October by James M. McCleary, a Cuyahoga County road engineer, whose connection with the building of these roads covers a period of 20 years.* Mr. McCleary not only confessed errors in construction and the slowness with which mistakes were corrected, but pointed out in detail many of the mistakes, one admitted defect particularly being a lack of drainage.

Even where some effort at drainage was made, a confession followed that the very methods employed in drainage were such as would be expected to bring about the moist condition underneath the pavement and develop the cracks from the effects of low temperature of which you speak. So these cracks are not in roads which are good examples of *first-class construction.*

Quite the contrary is found in the fact that there are perhaps an equal number of miles of brick roads and streets in Cuyahoga County, which approach examples of *first-class construction.* In these, no cracks whatever appear, a condition that may be expected to obtain in cases of properly constructed brick streets, where the danger of cracking is intelligently and scientifically provided for.

Strictly speaking, it may be a fallacy that a brick pavement when once well laid, needs no repairs whatever. While I do not want to be in a class that would take such an extreme position, still the public should know the truth; which is, that if a brick pavement is properly constructed, the repairs are merely a negligible consideration and do not amount to even as much as Governor Glynn declares, to wit: $50 per mile per annum. This is not an extravagant statement to make in view of the fact that a great many miles of brick streets and roads have been built and are in constant use with much more than an average traffic, and have not needed a dollar for repairs, and will probably not need any repairs for many years to come.

I think your suggestion as to the manner and method of repair where these repairs are needed is unfortunate. In the judgment of the writer, the only practical and economical way to repair a brick road is to restore the pavement to a condition in accord with the original construction both as to manner and method. This is not quite so easily done as in the way suggested.

WILL P. BLAIR.

Sec'y, National Paving Brick Manufacturers' Association.

Cleveland, Ohio, July 11, 1914.

*For abstract of Mr. McCleary's paper see "Engineering News," Oct. 16, 1913, pp. 749, 750.—Ed.

The Coffer-Dam for the 46th St. Pier, North River, New York City

The deepest and one of the largest coffer-dams ever built is now under construction on the North River at the foot of West 46th St., Borough of Manhattan, New York City, to be used in laying bare the site of the shore end of a new 1000-ft. pier being built there by the City of New York. The coffer-dam is made up of continuous cells of steel sheet piling and is similar in construction to the dam used in the construction of Black Rock harbor in Buffalo, and somewhat similar to the famous coffer-dam, which inclosed the ruins of the "Maine" when the wreck of that vessel was raised some years ago. Profiting by the experience gained in these two dams, however, the engineers are backing the sheet-pile cells with a very heavy filling of riprap, so that in effect the pockets of steel sheet piling form the seal of the coffer-dam, and are held in place by the riprap fill.

Design of the Pier

The increasing demands of the extraordinarily large vessels now berthing in the North River has led the City of New York to the construction of 1000-ft. piers in the North River and the location selected is the Manhattan side of the river north of 42nd St. The first construction in this new location was authorized for the foot of 46th St. about a year ago. It was intended at that time to build a 1000-ft. pier directly at the foot of 46th St. with berths on either side and to defer the construction of a half pier at 44th St., providing an additional berth to the north, until property rights could be acquired later. However, within the past few months the city has acquired full rights at 44th St., so that the work now under construction comprises a pier 150 ft. wide and 1000 ft. long, at the foot of 46th St. with berth to the north and to the south 1000 ft. long, and a half pier on the northerly side of 44th St. 1000 ft. long with a 1000-ft. berth to the north.

The coffer-dam, which is to inclose the shore end of this area, extends then from 47th St. to 44th St. The whole contract comprises the placing of about 3500 tons of steel in the coffer-dam, 99,000 cu.yd. of riprap in the embankment, the removal of 76,000 cu.yd. of rock and the placing of 14,000 cu.yd. of concrete masonry. The whole basin created by the coffer-dam will cover an area

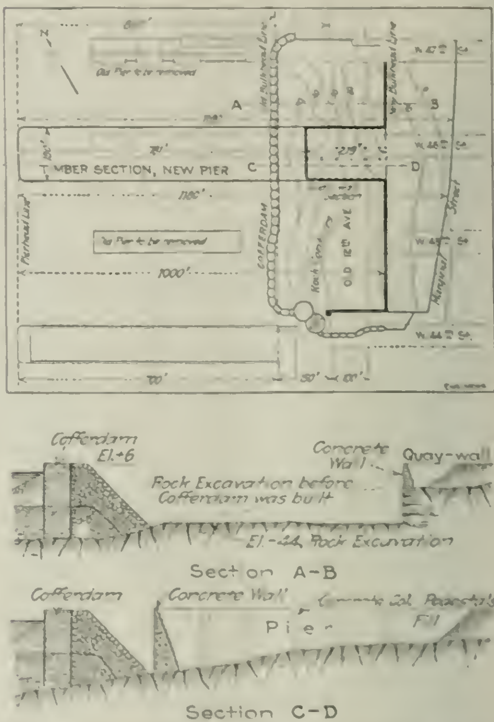

Fig. 1. Plan and Sections of New Pier at Foot of W. 46th St., North River, New York City. Showing Location of Coffer-Dam

Fig. 2. View of [illegible], Foot of W. 46th St., July, 1914, Showing Coffer-Dam Partly Completed and Shore Excavation Made

of about 800 ft. in length and 300 ft. in width, requiring about 55,000,000 gal. of unwatering. The greatest head on the coffer-dam will be over 65 ft.

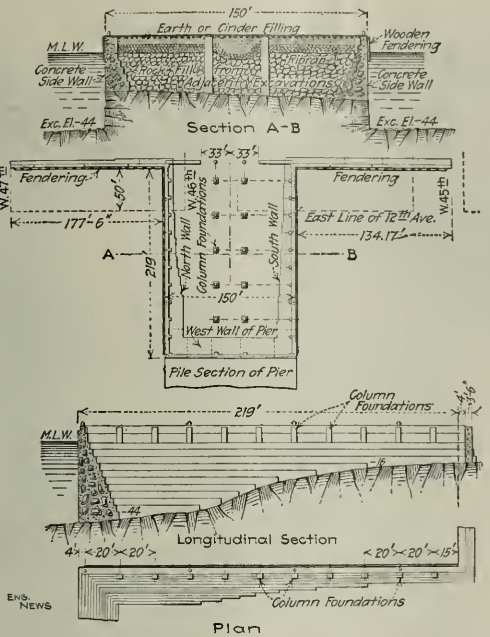

Fig. 3. Details of Quaywall and Fill Construction of 46th St. Pier

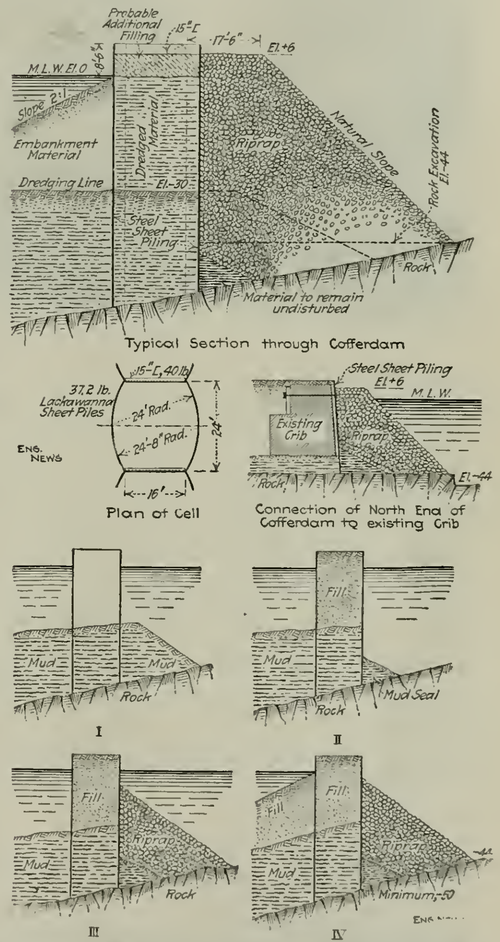
The pier-head line in the North River at this location is 700 ft. riverward from the old bulkhead line, so to provide a 1000-ft. dock it is necessary to extend the bulkhead line inshore some 300 ft. Borings and soundings at the site showed the following conditions: Along the new bulkhead line rock was found at an average depth of about 20 ft. below mean low water. Running outshore at a distance of about 220 ft. rock was found at a depth of about 44 to 50 ft. below water. From this point outshore the rock slopes off at a uniform grade, at the pier-head line rock was found at a depth of about 150 ft. below mean low water with an overlying layer of soft mud. The ships for which the new docks are designed require nearly 40 ft. of water, and it was felt that excavations should be carried to at least a depth of 44 ft. below low water to insure safety in berthing in extreme low tide. It, therefore, was necessary to excavate at the shore end of the berth a ledge of rock running from 20 ft. in depth near the bulkhead line to zero about 250 ft. from that line.

At the same time the nearness of the rock to the surface near the shore line made exceptionally desirable the construction at that end of the pier of a filled-in quaywall rather than the ordinary pile-pier construction common to New York harbor. For these reasons it was decided to build the pier 1000 ft. long with a shore end of 219 ft. of gravity section concrete wall filled behind with riprap and earth and with the outshore 781 ft. of ordinary timber-pile construction. On p. 194 of this issue is a note, with a view, describing the test piles driven in preparation for this outshore section.

For the construction of the shore section, underwater excavation of the rock was considered, but because it was very necessary that the rock bottom as excavated should



(Note that the outshore fill shown in stage IV is deposited in part in stage III. See text.)

Fig. 4. Details of Coffer-Dam for 46th St. Pier and Diagram, Showing Successive Stages of Construction

be comparatively smooth and well below the bottoms of the vessels entering the berth and furthermore because in the estimate it proved more economical, it was decided to inclose the entire shore area with a coffer-dam, to unwater the area and to excavate the dock areas by rock excavation in the open, leaving the rock under the quaywall and pier section at its natural elevation and leaving, furthermore, a sheer wall at the quaywall, so that there would be presented a smooth, vertical wall from the river bottom at the dock to the top of the pier. (See Fig. 3 for details of the pier design.)

Fig. 5. View of Coffer-Dam under Construction

The coffer-dam to be built had to be driven in 20 to 30 ft. of water with an underlying mud to the rock surface, which required a total length of piles making up the coffer-dam of some 70 ft. This extreme depth, together with the very heavy head that the dam would have to carry, required an exceptional type of dam and the engineers decided to utilize the cellular sheet-pile method noted above. In the Black Rock harbor coffer-dam, at Buffalo, and particularly in the coffer-dam of the "Maine," which was considerably deeper than the Buffalo dam and therefore more nearly resembled the problem in the North River, a first attempt was made to insure stability of the dam by filling the cells with the mud or silt excavated from behind the dam. In the "Maine" this proved quite unsuccessful and it was necessary to fill in behind the dam with riprap. In the North River dam, therefore, it was decided to forestall any future movement of the dam by providing at the beginning a heavy fill of riprap against the inside of the sheet-pile fill.

Design of Coffer-Dam

The dam used (Fig. 4) consists of a corewall formed of cellular pockets of interlocking sheet piles, each pocket being about 16 ft. in width and 24 ft. in length with an embankment of riprap on the shore side with a width of $17\frac{1}{2}$ ft. and an elevation 6 ft. above mean low water, with a natural slope of 1 on 1 and with an embankment of earth along the outshore, or water face up to mean low water.

The cells are made up of the Lackawanna sheet piles of the 37.2-lb. sections, capable of safely resisting a jaw tension of 9500 lb. per lin.in. Each cell consists of two slightly rounded outer walls with joining transverse straight walls, which are additionally braced by a heavy channel crossing the wall and bolted to each separate sheet pile (Fig. 6). This cross channel was devised to give additional stability during the construction of the pockets. The ends of the coffer-dam are joined at the north end to an existing crib by framing one of the sheet piles of the last cell into a straight single line of sheet piles, which in turn are tied back with tie rods to the interior of the crib work (Fig. 7). At the south end the shore end runs up to above water with a single line of sheet piles. The connection of one cell to another is made with a three-way special sheet pile, designed for this purpose. One may be noted in Fig. 7.

As is shown in Fig. 1, two of the cells are circular in plan and of much larger size than the standard; this is imposed by the necessity of clearing the corner of the existing pier at the foot of 11th St.

The progressive steps in building the dam are shown on the diagram on Fig. 4. The first step in the construction was to destroy the inshore portions of the old existing pier, then to dredge to rock within the area included between the new bulkhead line and a point about 240 ft. west of it. This included both under-water dredging and the excavation of a previous shore section. The coffer-dam cells were then driven across the opening just riverward of the dredged section, so that the piles were driven through an overlying 20 ft. or more of mud and silt. These conditions are shown under step I, in Fig. 4.

Step II was to tub out the mud lying on the shore side of the coffer-dam and into the cell of the dam, leaving a seal of the mud at the inner toe of the dam. Step III is to place the fill of mud up against the river side of the

Fig. 6. A Brace in the Transverse Wall between Two Cells of Coffer-Dam

coffer-dam and to dump the riprap against the shore side of the dam, and step IV will be to pump out the dam. Examination of the diagram showing these steps will show that at various times during the process the dam would be in rather precarious state of equilibrium if the processes indicated on the steps were continued entirely across the dam. For instance, in step III, if the riprap were placed entirely before the fill was placed on the river side of the dam, as the diagram shows in step III, there would be a pronounced tendency to turn over toward the river.

In order to avoid such possibility the filling and excavating on either side of the coffer-dam are now being carried out with extreme caution in alternate sections along the dam, so that no great length of the dam is subjected to excessive pressures from either side at any one time.

Fig. 7. North End of Coffer-Dam, Showing Connection to Existing Crib

The present state of the dam is shown in the large view in Fig. 2. A considerable portion of the cells has been driven and the dredges are working, filling the cells and the dam. The fills inside the cells cannot be completely made with the tubbed-out material inside the dam and the fills in upper part of the cells are to be made by wagons from shore, driven out over the coffer-dam on plank laid across the top of the cells.

Some little trouble has been experienced in driving the closure piles of each cell and in two cases at least the driving has put such a strain upon the pile as to cause them to break. Fig. 6 shows a break of such a nature in one of the cross walls between two adjoining cells.

Personnel

The pier has been designed and is being constructed by the Department of Docks and Ferries of the City of New York, R. A. C. Smith, Commissioner of Docks and Ferries, and C. W. Staniford, Chief Engineer of the Department.

Holbrook, Cabot & Rollins, of Boston and New York, hold the contract for the work which has been described.

Standards of Water Purification and Sewage Treatment

The following standards of water purification are a result of a conference of eminent sanitary engineers, held at the request of the International Joint Commission, to aid the Commission in its investigation of the pollution of the Great Lakes. The engineers asked to participate were George W. Fuller, George C. Whipple and Earle B. Phelps for the United States and F. A. Dallyn, W. S. Lea and Theo. J. Lafreniere for Canada. These engineers were submitted a list of questions on which a general discussion took place. As a result, a resumé was drawn up and signed by all of the engineers except Mr. Dallyn, who objected to several points and asked for the elimination of paragraphs 5, 7 and 11. The other members could not consent to this, so Mr. Dallyn's name was left off the statement, which follows:

1. Speaking generally, water supplies taken from streams and lakes which receive the drainage of agricultural and grazing lands, rural communities, and unsewered towns are unsafe for use without purification, but are safe for use if purified.

2. Water supplies taken from streams and lakes into which the sewage of cities and towns is directly discharged are safe for use after purification, provided that the load upon the purifying mechanism is not too great and that a sufficient factor of safety is maintained, and, further, provided that the plant is properly operated.

3. As, in general, the boundary waters in their natural state are relatively clear and contain but little organic matter the best index of pollution now available for the purpose of ascertaining whether a water-purification plant is overloaded is the number of B. coli per 100 c.c. of water expressed as an annual average and determined from a considerable number of confirmatory tests regularly made throughout the year.

4. While present information does not permit a definite limit of safe loading of a water-purification plant to be established, it is our judgment that this limit is exceeded if the annual average number of B. coli in the water delivered to the plant is higher than about 500 per 100 c.c., or if in 0.1 c.c. samples of the water B. coli is found 50% of the time. With such a limit the number of B. coli would be less than the figure given during a part of the year and would be exceeded during some periods.

5. In waterways where some pollution is inevitable and where the ratio of the volume of water to the volume of sewage is so large that no local nuisance can result, it is our judgment that the method of sewage disposal by dilution represents a natural resource and that the utilization of this resource is justifiable for economic reasons, provided that an unreasonable burden or responsibility is not placed upon any water-purification plant and that no menace to the public health is occasioned thereby.

6. While realizing that in certain cases the discharge of crude sewage into the boundary waters may be without danger, it is our judgment that effective sanitary administration requires the adoption of the general policy that no untreated sewage from cities or towns shall be discharged into the boundary waters.

7. The nature of the sewage treatment required should vary according to the local conditions, each community being permitted to take advantage of its situation with respect to local conditions and its remoteness from other communities, with the intent that the cost of sewage treatment may be kept reasonably low.

8. In general, the simplest allowable method of sewage treatment, such as would be suitable for small communities remote from other communities, should be the removal of the larger suspended solids by screening through a ¼-in. mesh or by sedimentation.

9. In general, no more elaborate method of sewage treatment should be required than the removal of the suspended solids by fine screening or by sedimentation, or both, followed by chemical disinfection or sterilization of the clarified sewage. Except in the case of some of the smaller streams on the boundary, it is our judgment that such oxidizing processes as intermittent sand filtration, and treatment by sprinkling filters, contact beds, and the like, are unnecessary, inasmuch as ample dilution in the lakes and large streams will provide sufficient oxygen for the ultimate destruction of the organic matter.

10. Disinfection or sterilization of the sewage of a community should be required wherever there is danger of the boundary waters being so polluted that the load on any water-purification plant becomes greater than the limit above mentioned.

11. It is our opinion that, in general, protection of public water supplies is more economically secured by water purification at the intake than by sewage purification at the sewer outlet, but that under some conditions both water purification and sewage treatment may be necessary.

12. The bacteriological tests which have been made in large numbers under the direction of the International Joint Commission indicate that in some places the pollution of the boundary waters is such as to be a general menace to the public health should the water be used without purification as sources of public water supply, or should they be used for drinking purposes by persons traveling in boats.

13. It is our judgment that the drinking water used on vessels traversing boundary waters should not be taken indiscriminately from the waters traversed unless subjected to adequate purification but should be obtained preferably from safe sources of supply at the terminals.

14. While recognizing that the direct discharge of fecal matter from boats into the boundary waters may often be without danger, yet in the interest of effective sanitary administration it is our judgment that the indiscriminate discharge of unsterilized fecal matter from vessels into the boundary waters should not be permitted.

A Combination Brick and Asphalt Pavement.—Sheet asphalt for the middle portion of the street and brick pavement on the sides and gutters is suggested by the City Engineer of [illegible], as a solution of that city's paving problems. It is claimed that this type of pavement has proved successful in other cities.

A Relic of Some of New York City's Early Water-Works

The accompanying views show the demolition of a cast-iron storage tank of the Manhattan Co., built about 1800, at the corner of Reade and Centre Sts., New York City, as a part of the water-works which supplied the lower part of the city from about 1799 until the introduction of Croton water in 1842.

Walled in by an old building, this interesting relic has existed for over 100 years, forgotten by practically every-one but the owner of the property, the Manhattan Co., which, due to one of those curious legal fictions, must maintain the semblance of a water-works plant in order to keep its charter; and this charter of the Manhattan Co. is a valuable document, since, under a "joker" clause, it has built up one of the greatest banking institutions in the city. The water-works company will continue by a similar fiction of maintaining a 25-ft. diameter well, which is under the tank and its masonry substructure.

FIG. 1. DEMOLISHING OLD CAST IRON WATER TANK OF THE MANHATTAN CO., NEW YORK CITY

THE EARLIEST CITY WATER WORKS.—New York City had a water works system as early as 1774, when Christopher Colles built a reservoir on Broadway near the present Leonard and Franklin Sts., together with a pumping plant operated by two Newcomen's atmospheric steam engines, and water mains in many of the downtown streets, of pipes made of bored logs. These were in use in 1776.

but the War of the Revolution and accompanying troubles put an end to the water-works company.

History of the Manhattan Company—From then until the Manhattan Co. began operations in 1799, the city had no public water-supply. This granting of a charter to the Manhattan Co. was a historic event, and thereon hangs a tale, which is related in a booklet published by the Manhattan Co., as follows:

Fig. 2. Cast-Iron Floor Plates of Old Tank

Corporate banking in New York began with the organization of the Bank of New York by Alexander Hamilton in 1784, which received its charter in 1792. For 15 years this bank, together with the New York branch of the first Bank of the United States were the only banks doing business in either the city or state of New York. With Hamilton and the Federalists in control of the legislature, new bank charters were unobtainable. This monopoly of banking facilities in the city and state was of great strategic value to the political party in control, and naturally aroused jealousy and resentment among the members of the opposition, whose leader was Aaron Burr.

In 1798 New York City suffered from a severe yellow fever epidemic, which was attributed to an inadequate and inferior water supply. Upon the assembling of the legislature in 1799, an association of individuals, among whom Aaron Burr was the moving spirit, applied for a charter for the purpose of "supplying the city of New York with pure and wholesome water." With a capital of $2,000,000 the project was an ambitious one for those days, and, as there was considerable uncertainty about the probable cost of the water-works system, a clause was inserted in the charter permitting the company to employ all surplus capital in the purchase of public or other stock, or in other monied transactions or operations, not inconsistent with the constitution and laws of New York or of the United States.

A great effort was made to defeat the charter on account of this clause granting the company banking privileges. But the necessity for a proper water-works system, which could be secured only by the organization of a responsible company with large capital, carried it through the legislature, and it received the governor's signature.

The first meeting of the directors was held on Apr. 11, 1799. Dan Ludlow was chosen president, and the following minute was made:

The principal object of this incorporation being to obtain a supply of pure and wholesome water for the city of New York.

Resolved, That Samuel Osgood, John B. Coles and John Stevens be a committee to report with all convenient speed the best means to be pursued to obtain such supply.

On May 6, 1799, the water committee was empowered to contract for as many pine logs as they might think necessary for pipes, and also for boring the same.

A number of wells were sunk, reservoirs and tanks built, and the distributing system extended generally through the city south of city hall.

About 1836 the system was extended north along Broadway as far as Bleecker St., and at that time the company had about 25 miles of mains and supplied 2000 houses.

A 40x20-Ft. Cast-Iron Tank—Of the reservoirs operated by the Manhattan Co., the cylindrical cast-iron tank at Reade and Centre Sts. has been apparently the sole survivor. This tank was an interesting example of early 19th century water-works engineering. It was about 40 ft. in diameter, built of cast-iron segments about $2\frac{1}{2}$ ft. wide by $4\frac{1}{2}$ ft. high and fully $\frac{5}{8}$ in. thick. The plates were bolted to one another through outside flanges on all four sides of the plates and each plate had a transverse rib in the middle. The inside of the tank presented a smooth surface. The joints between the plates were evidently filled with an iron cement, apparently salamoniac and iron filings. The tank was about 20 ft. high. The cast-iron plates were imported from England.

As one of the views shows, there was about 4 ft. of water in the bottom of the tank; from all appearances, there had been water there from time immemorial. When the water was removed, there was a black, slimy, greasy sediment 4 or 5 in. deep, of about the consistency of axle-grease, which gave eloquent evidence of the character of the water that has filled the tank during recent years, at least. The bottom plates, after this deposit had been removed, showed almost no corrosion. According to con-

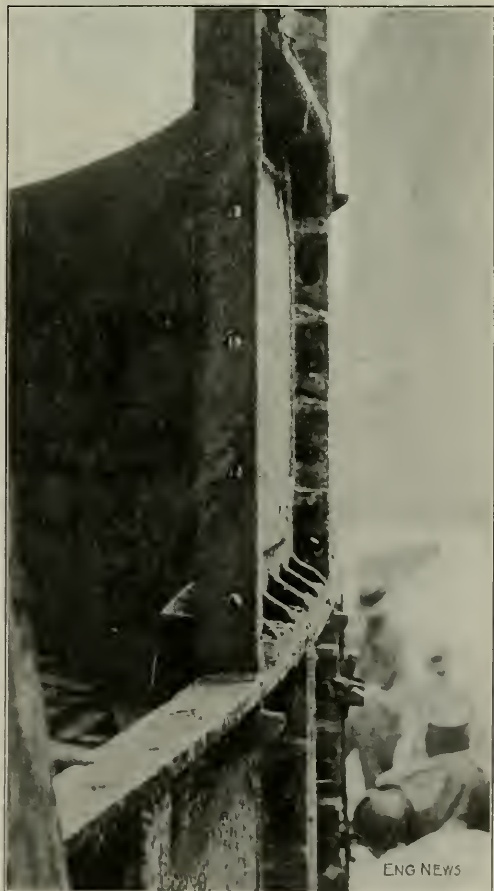


Fig. 3. Near View of Cast-Iron Plates

temporary reports the water was always notoriously bad.

All the sole plates are still good sound iron; few had apparently lost more than one-quarter of their original thickness, although, in removing the plates, rust scale on the exterior of the tank fell off in sheets several feet square. It is, of course, impossible to tell whether the interior was ever painted or coated in any way, but evidently the best protection of all had been the scale itself, and the good quality of the iron.

FIG. 1. A PRIMITIVE GATE-VALVE; DUG UP IN PARK ROW, NEW YORK CITY, IN 1900

The masonry substructure is of curious construction. It is formed of a central pier with radial arches of brick masonry extending to an outside row of piers. The inlet and outflow pipes were cast or wrought iron; and the valve on the outflow pipe was of a gate-valve design, with a rising stem screw.

Proposed Improvements in Municipal Street Cleaning; New York City

In a recent report on a proposed model street-cleaning district in the Borough of Manhattan, New York City, J. T. Fetherston, Commissioner of Street Cleaning, points out the possibility of introducing many improvements and economies. The system now in use in New York City is practically the same as that installed by Col. G. E. Waring over 17 yr. ago.

The main feature of the new plan, which is novel only in its adaptation to municipal conditions, replaces horse-drawn vehicles with power-driven motor tractors, each fitted with three types of trailers; one for street flushing or sweeping, one for refuse collection, and the third for plowing, sweeping and hauling snow. The remainder of the equipment will consist of standard types of covered receptacles for holding garbage or ashes, and a transfer station or dump provided with power-operated devices for handling refuse.

TRACTOR-TRAILER OUTFITS—For the proposed model district, 12 tractors of the nominal 5-ton type, with 36 trailers, will be required. These will be equivalent to 36 single trucks and constitute the main feature in the new scheme. No other city has taken up the tractor-trailer system, but it is successfully employed by private companies. Its adoption for municipal street cleaning, Mr. Fetherston believes, will solve the problem of decreasing the fixed charges by extending the functions of the trailers and the hours of work of the tractors.

Each tractor, as already noted, will be provided with three types of trailers. For collecting refuse, a trailer body fitted with removable compartments to hold at least 10 cu.yd. of refuse will be provided and so designed that material from the standard cans will be transferred to an appropriate compartment without creating dust or nuisance. All classes of refuse will be collected at one time, and not more than one collection trip per day will be made through any street. This will result in all cans being removed from sidewalks and areas except at the removal period, which can be closely timed for every street.

For cleaning streets, a trailer containing a water tank holding about 1500 gal. with sprinkling, flushing and revolving-broom attachments will be furnished, and for snow work a plow and revolving broom, following street-railway practice, is contemplated. Manufacturers of auto trucks have been consulted as to cost and feasibility of the combination tractor-trailer system and have decided the apparatus to be both practical and economical.

DUMP AND TRANSFER STATION—The transfer station or dump will consist of a closed shed on a pier following the general type of shed built along the waterfront, using structural-steel members covered with galvanized-iron sheathing. An electrically operated telpher system will unload refuse containers from vehicles and transfer the material to scows moored alongside the dock. Until the existing contracts for final disposition expire on Jan. 1, 1917, it will be necessary to use the present scows, but later they will be fitted with steel compartments or containers to hold refuse, instead of piling it loosely on the deck to be scattered on the water by the wind while in transport. On account of the picking contract now in force, it will be necessary to construct a temporary rubbish incinerator on the pier, but on the expiration of this agreement (Jan. 1, 1917) all trimming and picking will be eliminated at the transfer station.

The transfer station will become the headquarters for the district and will be provided with an office, employees' dressing rooms, lockers, shower baths and all suitable appurtenances for the work. Temporary storage of refuse pending the arrival or shifting of scows will be provided by means of 24 steel receiving tanks each of 20 cu.yd. capacity. In operation, such a transfer station will eliminate present nuisances at the waterfront dumps.

ESTIMATED COST—The model district proposed contains a population of 130,000, an area of 900 acres, has 50 miles of streets and 807,555 sq.yd. of pavement. The district includes wholesale and retail business, residences, tenements, manufacturing plants, apartment houses, pub-

lic institutions—in fact is thoroughly representative of city conditions. The accompanying Table I shows the estimated cost of the plant described for this district.

TABLE I—COST OF TRACTOR-TRAILER PLANT

Equipment	Total Investment
Shed at dock, 12,500 sq.ft. @ $1.35	$16,875
Telpher track, 1500 lin.ft. @ $5	7,500
Telpher switches, 8 @ $200	1,600
3 telphers complete, $5000	15,000
Temporary rubbish incinerator and belt	10,000
Plumbing and heating	3,000
Electrical work	3,000
Office and equipment	1,000
24 steel receiving tanks (8x8x10) @ $300	7,200
12 tractors and trailers complete @ $10,000	120,000
26,000 special refuse receptacles @ $1.25	32,500
3 auto runabouts	1,800
Engineering—Design and tests	21,500
Contingencies	12,025
Total	$253,000
Annual interest @ 4½%	$11,385

The accompanying Table II gives the estimated cost of operation of the tractor-trailer plant and equipment, which represents an estimated saving of $54,312 over the present methods.

TABLE II—ESTIMATED ANNUAL COST OF OPERATION, MAINTENANCE AND FIXED CHARGES, TRACTOR-TRAILER METHOD

Item	Street Cleaning	Refuse Collection	Snow Work	Totals
Operation and Maintenance	$186,300	$77,412	$15,688	$279,400
Interest	2,365	5,081	1,059	8,505
Depreciation	998	15,643	439	17,080
Totals	$189,663	$98,136	$17,186	$304,985

Municipal Ownership and the Commissioner of Utilities at Port Arthur, Ont.

It is doubtful wheter any other city this side of the Atlantic has gone farther in municipal ownership than Port Arthur, Ont. It owns and operates a street-railway system, electric lights, power service, telephones and water-works. In addition to its extensive ownership of public utilities it adopted what is virtually the city-manager plan about three years ago, or before the plan was more than launched in the United States.

The City Council of Port Arthur appointed J. J. Hackney Commissioner of Utilities in August, 1911. Mr. Hackney has direct control of the eight following city departments: Street Railway; Electric Light; Power; Telephone; Water-Works; Collection; Purchasing; Street Lighting. Besides, he has a general supervision of the Fire and other Departments of the city.

Mr. Hackney informs us that besides making all purchases, all bills are approved by him before being passed by the City Council. He also states that he reports to the Council and that the relations between him and the Council "have been very, very agreeable," with "an entire absence of friction."

The tax rate of Port Arthur for 1914 is 20.5 mills on the dollar, including the school tax. Mr. Hackney states that this is about the lowest rate in Canada for the current year and says considerable credit therefor "is due to the surpluses from the utilities."

The financial results of municipal ownership at Port Arthur are thus summarized by Mr. Hackney:

The following are the gross gains of the Utilities Department for 1913, showing the percentages on the capital invested. This would be the amount that in the case of private companies would be available for dividends. Of course, in Canadian municipal corporations we issue debentures for our capital construction, and take care of interest and sinking fund thereon.

ELECTRICAL DEPARTMENT

Gross revenue	$174,733	
Operating expenses	66,869	
Gross gain		$107,864

TELEPHONE DEPARTMENT

Gross revenue	$46,097	
Operating expenses	26,573	
Gross gain		$1,728

WATER-WORKS DEPARTMENT

Gross revenue	$51,465	
Operating expenses	23,833	
Gross gain		$27,631

STREET RAILWAY DEPARTMENT

Gross revenue	$288,724	
Operating expenses	$190,956	
Gross gain		$97,768

If we take the utilities individually, the gross revenue would show a good return on the amount invested, with the exception of the water-works, as follows: Street railway, 10½%; electrical, 16%; telephone, 6½%; water-works, 1¼%.

The water-works department is under heavy expenditure just now for a new pump-house, intake and force mains, from which there will be no revenue until next year, when this department will show up to much better advantage.

That the consumer's rates at Port Arthur compare favorably with those in other cities, Mr. Hackney thinks is borne out by the following:

STREET RAILWAY DEPARTMENT—Tickets, 8 for 25c. and 6 for 25c.

ELECTRICAL DEPARTMENT—Domestic: 4c. per 100 ft. area charge plus 2½c. per kw.-hr., less 10 per cent. Commercial: 6c. for the first hour's daily use of installed cacity, 2½c. for all above, less 10 per cent. Power: Unrestricted power, $25 per hp. per annum for 24-hr. power, $20 per hp. per annum for 10-hr. power.

Metered power—A. C. service charge of $1 per hp. per month, and a consumption charge of

1.3c. per kw.hr. for the first 50 hr. monthly use of maximum demand.
0.9c. per kw.hr. for all additional consumption up to the second 50 hr. monthly use, and
0.1c. per kw.hr. for all remaining consumption.

Metered power—D. C. service charge of $1 per hp. per month, and a consumption charge of

1.5c. per kw.hr. for the first 50 hr. monthly use of maximum demand.
1.0c. per kw.hr. for all additional consumption up to the second 50 hr. monthly use, and
0.15c. per kw.hr. for all remaining consumption.

TELEPHONE DEPARTMENT—Residence party line, $12 per yr.; residence single line, $15 per yr.; commercial, $30 per yr.

WATER DEPARTMENT—10c. per 100 cu.ft. for the first 1000 cu.ft., and then 7c. per 100 ft. for all above, plus meter rent.

The Production of Sand and Gravel in the United States in 1812, reported to the U. S. Geological Survey by Ralph W. Stone, was 68,318,877 short tons, valued at $23,081,555, as compared with 66,846,959 tons in 1911, a net increase of 1,471,918 tons. Sand for building purposes constitutes about ⅓ of the total production. In 1912, 23,632,157 tons of building sand were produced, valued at $7,904,321, as compared with 24,-614,342 tons, valued at $7,719,286 in 1911, a decrease in production of 1,082,185 tons, and an increase in value of $185,035. The average value of building sand per ton increased from 31c. in 1911 to 33½c. in 1912. Mr. Stone attributes this condition to the higher wages paid to laborers.

The tonnage of gravel produced exceeds that of sand. In 1911 nearly 30,000,000 tons of gravel for concrete paving, filter beds, roofing, road-making, railway ballast, etc., was produced, as against about 26,600,000 tons in 1911. The increase in average cost per ton of gravel was from 25c. to 26c. Mr. Stone says that although wages paid to laborers have probably increased and tended to raise the cost of gravel he believes that the introduction of machinery during 1912 tended to reduce the average cost per ton.

The heaviest building-sand producer in 1912 was New York, which produced 4,126,271 tons. Next in order, all exceeding 1,000,000-tons production, were the following states: Illinois, Missouri, Pennsylvania, Ohio, Indiana, New Jersey and Iowa. The greatest gravel-producing state in 1912 was Illnois with 3,481,638 tons. Next in order, all exceeding 2,000,000 tons capacity, were Ohio, Indiana and New York.

Street Damage from a Sewer Collapse, Newark*

By Edward S. Rankin†

Shortly after midnight on July 7, during a heavy downpour of rain, a section of the sewer on Bank St., Newark, N. J., between High and Plane Sts., about 20 ft. in length, collapsed, completely blocking the flow and forcing up the water through a manhole, to the surface of the street.

The street has a steep grade, approximately 7%, and was paved less than a year ago with grouted granite on a concrete base. The sewer, built of brick in 1871, parallels the surface at a depth of about 13 ft. It is egg-shaped, 3x4.5 ft., and was constructed in a rock cut. Apparently, no care had been taken to properly fill the voids between the rock and the masonry. The sewer theoretically is large enough to care for the storm water tributary to it during the heaviest rainfalls and no complaints have ever

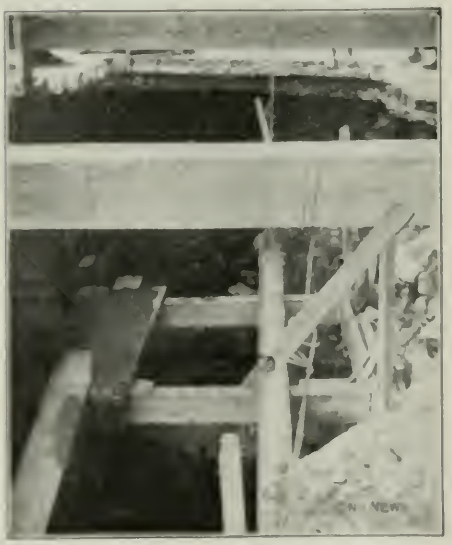

Fig. 1. Large Hole in Bank St. at Point of Sewer Collapse

(The brick sewer is 13 ft. below street level. The cast-iron water main shown was not disturbed.)

been received of flooding in this section, although much heavier rainfalls have been experienced.

The rising water somehow found its way between the concrete foundation of the pavement and the granite blocks, and the latter being absolutely watertight were lifted bodily from the foundation by the head of water caused by the steep grade of the street. The pavement for a distance of 300 ft. is more or less raised and buckled and in three places, about equal distances apart, badly arched. The upper and middle breaks take the form of transverse arches with a span of about 15 ft., and a rise of 18 in. At the lowest break, a section of the pavement about 3x8 ft. was lifted completely from its bed and thrown several feet from its original position.

While the breaking of the sewer was undoubtedly the primary cause of the trouble, it is impossible to determine

Fig. 2. Bulged Granite-Block Pavement

(Pavement was laid by the Hildreth Granite Co. in July, 1913. The 5-in. blocks were laid on a 1½-in. sand bedding on a 6-in. concrete bed of 1:3:6 mixture, which rested on rolled earth. The blocks were grouted with a 1:1 mixture. When the blocks were laid they were first flushed with very wet grout, then grout of creamy consistency was worked in between the joints. The whole was allowed to set for seven days and kept wet meanwhile.)

positively how this break could have damaged the pavement to such an extent. It seems probable, however, that the water escaped through loosely laid brick at the top of the manhole immediately below the cast-iron head, as a number of brick were found to be washed out at this point. The entire pavement for a distance of 300 ft. will probably have to be relaid, although it is believed that most of the concrete foundation will be found intact.

*[illegible] Hildreth Granite Co., [illegible] Broadway, New York City, who laid the pavement on Bank St., Newark.

†[illegible] Department of Sewers and Drainage, Newark, N. J.

The Report of the Commission of Inquiry on the "Empress of Ireland" Disaster

We briefly summarized in our last week's issue that part of the report of the "Empress of Ireland" Commission which dealt with the placing of the blame for the collision between the "Empress of Ireland" and the "Storstad." A part of the report which is of greater engineering interest deals with the question why the "Empress of Ireland" sank in so short a time after receiving the fatal wound.

The "Empress of Ireland" was a comparatively new vessel. She was built in 1906 to class 100 A1 at Lloyds. She had four complete steel decks running from stem to stern: the shelter deck, upper deck, main deck and lower deck. The upper deck was at its lowest point 21 ft. above the water line.

There were ten transverse water-tight bulkheads terminating in each case at the upper deck. These bulkheads were built in accordance with the recommendation of the British Board of Trade Bulkhead Committee of 1891. They were designed in accordance with recommendations of that committee so that any two adjacent compartments might be flooded without sinking the ship below the margin of safety line drawn below the upper deck. Twenty-four water-tight doors in these transverse bulkheads were of the horizontal sliding type, opened and closed by hand. All these doors appear to have been open at the time of the collision and the board concluded after hearing the evidence that nearly all the water-tight doors

on the starboard side between the main and upper decks remained open after the collision. A large proportion of the porthole openings in the side of the ship were also open when the collision occurred.

The stem of the "Storstad" penetrated the side of the "Empress of Ireland" some 21 ft., making a hole about 46 ft. in height, about 25 ft. of which was below water. The width of the hole it is impossible to ascertain, as there may have been some longitudinal ripping action as well as the direct contact. The commission concludes, however, that when the bow of the "Storstad" was withdrawn from the side of the "Empress," an area of no less than 350 sq.ft. was opened for the access of water to the hull.

The collision occurred in the immediate vicinity of the water-tight bulkhead between the two boiler rooms; hence these compartments with a combined length of 175 ft. were at once placed in communication with the sea. With both these compartments flooded the vessel would be sunk practically 9 ft. and if she remained on an even keel without listing, this would take the main deck 4 ft. below water amidships. She would still have had a metacentric height of just over 2 ft., however, and would have continued to float upright had the water-tight doors in the bulkhead above the main deck on either side of the flooded compartments been closed. With the water-tight doors open, however, water from the flooded compartments immediately entered the compartments adjoining. The reason for the great listing of the vessel was that the flooded boiler rooms were divided longitudinally by a coal bunker, steam-pipe passages, etc., which, while not by any means water-tight, considerably delayed the flow of the water from the starboard side to the port side. The commission concludes that the ship probably listed some 15 to 20°; and deep in the water as she was from the flooded boiler compartments, this would cause the water to pour in all along the starboard side of the vessel at the open port holes.

Conclusions

At the close of its report, the commission makes the following suggestions:

1. In order to prevent, if possible, disasters such as that into which we have been inquiring, we think that in foggy weather it would be desirable to close all watertight doors and port holes below the top of the watertight bulkheads, and to keep them closed until the fog has completely cleared. We think, also, that wherever practicable all watertight doors and portholes below the above level should be closed at sunset and kept closed until sunrise.

Precautions of the kind suggested would have the effect of securing the floatability of the ship in accordance with the intentions of the designer, whereas neglect of such precautions may lead to the foundering of a vessel which would otherwise have remained afloat.

2. The rapidity with which the vessel foundered after the collision made the life saving appliances on board of little use. Most, if not all, of the passengers were in bed when the vessel was struck, and there was an interval of only about fifteen minutes between the collision and the foundering. The list which the vessel took to starboard was so sudden and so great that the lifeboats on the port side were rendered useless almost at once. Some of them were indeed worse than useless, for they broke adrift and injured people as they clattered down the sloping deck. Of those on the starboard side, six only were launched, although the best was done in the short time available to get them into the water. These circumstances lead us to suggest that it might be desirable to consider whether rafts could not be placed in such a position on the upper deck that they would float automatically on the water as the ship sank. Such rafts would doubtless have to be attached to the deck in such a way as to prevent them from getting adrift in bad weather; but the attachments might be of a simple kind which could be loosened in a very short time.

NEWS NOTES

The Boiler of a Steam-Shovel Engine exploded at Wrenshall, Minn., on July 16, killing one man.

The Walls of a Frame Church Collapsed near Mount Vernon, Ark., on July 6. There was no one in the building at the time.

The Steamship "Mendoza" Went Ashore in a fog off Mogotes Point on the Argentine coast, on July 11. The "Mendoza" is a vessel of 2856 tons, belonging to the Hamburg-South American Steamship Co. She was built in 1894.

A Traction Engine Went Off a Dock at Glenwood, L. I., on July 18, when the engineer lost control. The engine was used in transporting sand to Roslyn. A derrick at a sand bank on the opposite shore lifted the engine from the channel without difficulty.

A Sewer Cave-In Laid to Rats—A 4-ft. brick sewer on Liberty St., between Broad and Nassau St., New York City, collapsed on July 20, shortly after 5 p.m. The cause of the collapse is said to have been the water rats gnawing at the mortar between the bricks.

A Cloudburst in Raleigh, N. C., caused considerable damage on July 14. The Carolina Power & Light Co.'s plant was shut down, and the basements of printeries were flooded to a maximum depth of 6 ft. The rainfall is reported at 3.4 in. in one hour, the heaviest in Raleigh in 26 years.

A Cave-In in the Balkan Mine at the Alpha location, near Iron River, Mich., on July 15, caused by quicksand, killed seven miners. The miners were drilling into a roof when the drill hit quicksand. The gang, about 30 in number, rushed toward the mouth of the tunnel. The mine was filled by the sand.

A Railway Collision between an electric excursion train and a Virginian Ry. freight train at a grade crossing near Norfolk, Va., on July 17, killed six persons. Press dispatches state that the crossing gates were down, and that the electric train crashed through these gates before striking the freight.

A Cloudburst in Bull Run, Penn., on July 15, moved 20 houses from their foundations, sweeping several into the Susquehanna River. A mill and a cigar factory were destroyed, as were the roads in the vicinity of the town. Bridges were washed away, and it is said that the fields were under 10 ft. of water.

A Suspension Bridge Over the Merrimac River Was Blown Over in a severe electric storm which swept a portion of the Merrimac Valley on July 12. The bridge was located at Tyngs Island. It was built by the Vesper Country Club six years ago, and cost $5000. It failed by breaking in two. The abutments on each side are intact.

A Street Car Fell Off a Viaduct at Superior, Minn., on July 9. According to press dispatches, the car was coming down the slope of the east portion of the viaduct when it jumped the track, crashed through the rail and dropped near the railway tracks underneath. The speed was moderate and the brakes set when the derailment occurred. There were no fatalities.

A Building Wall Collapsed in Northampton, Mass., on July 18, severely injuring one person. The damaged building is known as Union Block, and fronts upon Main St. The building houses several stores and lodge rooms. There were more than 100 people inside at the time, but the sound of cracking timbers gave sufficient warning for most of them to escape without injury.

A Heavy Rainstorm in Philadelphia on the afternoon of July 15, tore holes in pavements, flooded cellars, and interrupted street-car traffic. On Thompson St. a sewer caved in. A deep cut on the Philadelphia & Reading Ry. between Pennsdale and Roxborough was filled with 4 ft. of soft sand and debris. The official rainfall figure was 0.61 in. in 15 minutes, but in Manayunk, where the greatest flood damage is reported measurements taken by Supt. Winfield Gulle of the Manayunk Canal are said to show a precipitation of 2 in. in 20 minutes.

A Severe Wind Storm, with rain and hail, struck Henderson, Ky., on July 16, about 5:30 p.m. Several buildings were wrecked, roofs blown off, trees blown down, and much miscellaneous damage done. The municipal electric light plant was struck by lightning, while the rear end of the building was

[illegible] had the roof blown off. The street and inter-[illegible] lines were put out of service for some hours, due to [illegible] damage to the overhead [illegible] was [illegible] as a result of crossed wires. [illegible] in a residence which was crushed [illegible] being blown over upon it.

Municipal Docks at Trenton, N. J., are to be started with the construction of the new pier on the Delaware River at the foot of Federal St., the plans and specifications for which have just been approved by the city authorities. It is to be [illegible] ft. long and will cost about $70,000.

Engineering Activity on the West Coast—More than 2000 applications have been received by the City Engineer of San Francisco, Calif., for employment on the engineering staff [illegible] Hetch Hetchy municipal water supply project. ["Western Engineering," July, 1914.]

Tunnels Named for Engineers are to be a feature of the [illegible] cut-off line which the Baltimore & Ohio R.R. is [illegible] between Orleans and Little Cacapon, W. Va., 11 miles. The four tunnels will be named for four of the road's chief engineers as follows: James L. Randolph (1863-1883), J. M. Graham (1883-1904), D. D. Carothers (1904-1911), and Francis Lee Stuart (1911 to the present time). The new line shortens the distance by six miles and extends the four-track system east of Cumberland.

Commercial Attaches May Be Appointed for the principal United States legations in foreign countries, according to [illegible] of the Department of Commerce. It is proposed to have connected with each important legation a man of good business experience who will be competent to give advice in all cases in which matters come up affecting his country's commercial relations, and who will be able to make himself generally useful in promoting the commercial interest of the United States in the country to which he is accredited.

Concrete Road Construction Statistics—According to statistics gathered by the California State Highway Commission three times as much concrete was laid on roads and streets in California during 1913 as in any other state. The [illegible] laid last year was 1,766,000 sq.yd. in California, while the country's total was [illegible] sq.yd. Ohio was second with 6[illegible] sq.yd. The total amount of concrete roads and streets laid up to Jan. 1, 1914, in the United States amounted to [illegible] sq.yd., of which California is credited with 1,-[illegible] sq.yd. New York leads in present construction work with a total of 2,402,798 sq.yd.

A New German Canal from Berlin to Stettin, on the North Sea, was officially opened on June 17, and has been named the Hohenzollern Canal. The length of the canal from Berlin to its junction with the Oder River is about 60 mi. The canal is shallow, the vessels plying upon it having a draught of only [illegible] ft., but by using a length of 214 ft. and a width of [illegible] ft. a cargo of 6[illegible] tons can be carried. The cost of the canal has been about $1[illegible], and it is estimated that for several years there will be a deficit in its operating expenses of about $1[illegible] per annum. This will [illegible] the national treasury, however, but will [illegible] by the cities of Berlin, Charlottenburg and Stettin.

A 16-in. Gun, constructed at Watervliet Arsenal, was recently shipped to the Panama Canal fortifications, after tests at the Sandy Hook proving ground. The gun is [illegible] ft. long, weighs [illegible] tons and fires a projectile about 6 ft. long. The [illegible] weighs a ton, and is [illegible] ft. of [illegible] men are required to [illegible] the powder charge. The gun has a maximum range of about 22 miles. [illegible] the shell is revolving about its axis at about [illegible]. The [illegible] is [illegible] per sq.in. The [illegible] is [illegible] ft. per second [illegible]. The carriage for this gun is now [illegible] at the Watertown, Mass., arsenal, and will [illegible] until next spring.

First Decision under New York's New Liability Law—The [illegible] Commission in its first [illegible] [illegible] the Commission. This [illegible] on July 1 [illegible].

Awards Have Been Made in the Competition of the Barber Asphalt Paving Co. [illegible] in "Engineering News," Mar. 12, 1914, p. 586), for papers from engineering students on the subject of asphaltic materials for highway construction. The following students were awarded prizes of $100 each: Frederick O. X. McLoughlin, Columbia University; Harry Schindler, Cornell University; R. J. Fletcher, University of Georgia; John W. Hill, University of Illinois; Robert S. Johnson, Iowa State College; M. V. Holmes, University of Kansas; F. P. Gilbert, Massachusetts Institute of Technology; Harold J. LaLonde, University of Michigan; Benjamin Wilk, University of Minnesota; Alvin C. Smith, University of Nebraska; O. H. Gossweln, Purdue University; Alfred A. Berkowitz, Sheffield Scientific School; W. J. Campbell, Syracuse University.

The Power Plant, Substation and Transmission Line of the Truckee-Carson irrigation project will be leased by the U. S. Reclamation Service for ten years to the Canyon Power Co., of Oakland, Calif. This is subject to power sales already made. The bid of the Canyon Power Co. is at the rate of ¼c. per kw.-hr. for the excess power during the summer months (April to September, inclusive), and at the rate of [illegible] from October to March, inclusive. There is to be a minimum payment of $1200 per month during the summer months. The net income to be expected is approximately $14,000 per annum as a minimum, with a possible maximum of approximately $30,000 per annum; the more probable figures are about $20,000 per annum. A stipulation will be inserted in the contract for the protection of small consumers by limiting the price to be charged.

The Compensation of Railway Labor in the United States and in England was compared in an interesting statement issued by the Bureau of Railway News and Statistics. According to the British Board of Trade, there were 643,1[illegible] wage earners employed on the railways of Great Britain on Dec. 31, 1912. Of these 594,088 were classed as adults, and 49,047 as boys (i.e. under 18 years of age). The total is 44,365 more than in 1910, but only 21,791 over the number reported in 1907. The salaried staff is not included in the figures. In the United States, in 1913, the total was 1,714,6[illegible], also exclusive of officers. The compensation of British railway employees between 1901 and 1912, from available figures, increased from $146,0[illegible] to approximately $17[illegible]—about 19%. The number of workers, however, increased only 11%. During the same period, compensation of American railway employees, exclusive of officers, increased from $588,000,000 to $1,22[illegible], or [illegible]%, against an increase of 61.5% in the number of workers. The average pay of [illegible] railway employees in 19[illegible] was about $255 per year, and in 1912 $271. American employees in 1901 received $[illegible] each, and in 1912, $716 each.

The Morris Dam of the Waterbury, Conn., Water-Works, described in detail in "Engineering News," Mar. 2[illegible], 1911, is now complete with all its appurtenances. There is a 9[illegible]-ft. earth dam with a concrete core-wall, one of the largest structures of the kind in the Eastern States. The quantities in the completed dam are as follows: 46,[illegible] cu.yd. earth excavation, 96[illegible] cu.yd. rock excavation, 53[illegible] cu.yd. rolled embankment, 1[illegible],206 cu.yd. [illegible], 3[illegible] cu.yd. [illegible] masonry, [illegible] cu.yd. concrete [illegible], [illegible] cu.yd. rubble masonry, 369 sq.yd. granolithic finish, 11,[illegible] sq.yd. paving (including brook channel), 171 cu.yd. riprap, [illegible] cu.yd. broken stone, 362 lin.ft. 12-in. vitrified tile pipe, [illegible] lin.ft. 8-in. vitrified tile pipe, [illegible], [illegible] (temporary dam), 4[illegible] sq.ft. steel sheet piling, [illegible] lb. steel reinforcement, 51,[illegible] bbl. cement, 1 drain gate house, 1 service gate house.

Special care was taken with foundations. [illegible] the entire length of the dam, which is 11[illegible] ft. over all, masonry was started in the bottom of the trenches [illegible] the surface had been cleaned and washed with water [illegible] portions of loose rock or dirt removed. In the construction of the earthwork remarkably good material was available. All masonry is of concrete. The cement was at all times satisfactory. [illegible] quarry just west of the dam and was found of good quality except for the presence of a [illegible] amount of [illegible]. Concrete mixtures were [illegible] from 1:3:6 to 1:2:4 [illegible] used in construction of [illegible] which form the exposed surfaces of all walls [illegible] of the walls [illegible]. R. A. Cairns is City Engineer of Waterbury, from whose [illegible] the data quoted were taken.

No Proposals For Bonds, to be issued by the city and county of Denver to the amount of $[illegible] for construction

of new municipal water-works (as outlined in "Engineering News," July 2, 1914) were received by the Public Utilities Commission on July 20 when bids were to have been opened. The failure to receive bids is construed by the Utilities Commission as due to the opposition of bond houses, owing to the fact that $12,000,000 in bonds of the Denver Union Water Co. are now outstanding and no provision was made for their redemption in bonds of this issue (rather than as being reflection on the credit of the city). It is reported that a number of bond houses have signified their desire to purchase the bonds, provided the bonds of the water company are taken care of. Several informal offers of reservoirs, reservoir sites, irrigation works, and even covering the construction of a new plant in return for bonds have been received but have not been acted upon.

The Cucaracha Slide on the Panama Canal appears about to finally yield to the continued assaults upon it. Ever since water was admitted to the cut, dredges have been at work at the toe of the slide, endeavoring to excavate the earth and rock as fast as it flows in. As is generally known, this slide consists of a huge blanket of clay, covering originally some 47 acres, which is gradually moving down the hillside on the sloping bed rock like a huge glacier. The surface of the slide from the top to the bottom has the appearance of a series of waves, caused by the formation of the underlying rock over which the slide is moving. As much of the rock is soft and the pressure of the earth is great, a considerable amount of the rock has broken off and added its volume to the slide. For a considerable time, a navigable channel has been maintained past the slide, and there is now depth and width sufficient for ships to pass with a draught of 25 ft. The ladder dredge "Corozal" is now at work deepening this channel to the full depth. The movement of the slide has lessened of late. On July 20, 4800 lb. of 60% dynamite carried on the drill barge "Teredo" prematurely exploded, killing five men and injuring 18. Eight drill holes in the slide had just been charged when the explosion occurred.

A Report on the Panama Canal, both comprehensive and concise, will be a part of the proceedings of the International Engineering Congress to be held at the Panama-Pacific International Exposition, San Francisco, Calif., Sept. 20-25, 1915. Col. Goethals is chairman of the Congress and is to open the discussion on the Canal, which will be divided into the following heads:

(1) Col. Goethals' general report, (2) Dry excavation of the Panama canal by Col. Goethals, (3) Dredging the canal; (4) Terminal works, dry docks and wharves of the canal; (5) Meteorology and hydrology of the zone; (8) Designs of locks, dams and regulating works; (9) Methods of construction of same on the Atlantic side; (10) Same on the Pacific side; (11) Designs of locks walls and valves; (12) Spillways; (13) Gates of the canal; (14) Electrical and mechanical installation; (15) Emergency dams above locks; (16) Municipal engineering and domestic water supply in the zone; (17) Reconstruction of the Panama railroad; (18) Aids to navigation of the canal; (19) Geology of the canal zone; (20) The working force of the canal;(21) Sanitation in the zone; (22) Purchase of supplies for the canal.

Following Colonel Goethals' personal reports, each of these topics will be treated by the heads of departments or other attaches who were responsible for that part of the canal construction.

PERSONALS

Mr. George F. Baker, formerly with the Morgan Engineering Co., of Memphis, Tenn., has been appointed Assistant City Engineer of Dayton, Ohio.

Dr. Charles W. Berry, a physician of Brooklyn, N. Y., has been appointed Sanitary Supervisor of the New York State Department of Health, at a salary of $4000 per annum.

Mr. J. W. Carnes, recently Trainmaster of the Trinity & Brazos Valley Ry., at Teague, Tex., has been promoted to be Assistant General Superintendent, with headquarters at Teague.

Mr. F. K. Zook, former Engineer of Maintenance-of-way of the Northwestern Pacific R.R., has been promoted to be Chief Engineer of Maintenance and Structural Engineer of the railway.

Mr. Ross S. Marshall, formerly Superintendent of the Minneapolis & St. Louis R.R., at Oskaloosa, Wis., has been appointed Division Superintendent of the Seaboard Air Line Ry., at Richmond, Va.

Mr. H. B. Grimshaw, former Superintendent of the Seaboard Air Line Ry., at Americus, Ga., has been appointed General Manager of the Macon, Dublin & Savannah R.R., with offices at Macon, Ga.

Mr. William Bacon Gray, Assoc. M. Am. Soc. C. E., formerly General Superintendent of S. Pearson & Son, Inc., has opened an office for the general practice of civil engineering at 2 Rector St., New York City.

Mr. Samuel Wilson has resigned his position with the American City Bureau, New York City, and has been elected Secretary of the Chamber of Commerce of Johnstown, Penn., at a salary of $3600 per annum.

Mr. R. C. Watts, formerly in the employ of the New York, Chicago & St. Louis R.R., on grade elimination work in Cleveland, Ohio, has accepted a position in charge of equipment of the State Highway Department at Columbus, Ohio.

Mr. J. S. Calhoun, Jr., recently Sub-Inspector, Department of Public Works, Charleston, S. C., Navy Yard, has been appointed Superintendent of J. F. Jenkins & Co., of Osceola, Fla., contractors for the United States Post Office at La Fayette, La.

Mr. P. C. McArdle, Assistant State Highway Engineer of Illinois, has been appointed Acting Chief State Highway Engineer, to succeed Mr. A. N. Johnson, M. Am. Soc. C. E., resigned, as noted in our issue of June 25, to become connected with the Bureau of Municipal Research, New York City.

Mr. Frederick O. Ball, M. Am. Soc. M. E., has resigned as General Manager of the American Engine & Electric Co. (formerly the American Engine Co.), of Bound Brook, N. J., to engage in the manufacture of carbureters with his father, Mr. Frank H. Ball, M. Am. Soc. M. E., under the firm name of Ball & Ball, Detroit, Mich.

Mr. D. Howard Martin, M. Am. Soc. C. E., recently Division Engineer of the Pittsburgh & Shawmut R.R., Brookville, Penn., has been appointed Chief Engineer of James H. Corbett & Sons, Kittanning, Penn., contractors for Section 5 of the new Welland Ship Canal, with headquarters at Allanburg, Ont. The company is also engaged on railway construction contracts in the United States and Canada.

Mr. J. W. Williams, former Assistant Chief Engineer of the Northwestern Pacific R.R., has been appointed Chief Engineer of Construction to succeed Mr. William C. Edes, M. Am. Soc. C. E., now a member of the Alaska Engineering Commission. Mr. Williams is a native of Milan, Ohio, and has been in railway engineering work since 1901, when he was employed on the Santa Fé Central Ry. as chainman, levelman and transitman. He has been Assistant Chief Engineer of the Northwestern Pacific since 1907.

Mr. J. R. Bibbins, associated with Mr. Bion J. Arnold, M. Am. Soc. C. E., Consulting Engineer, Chicago, has been engaged by the law department of the city of Pittsburgh, Penn., in an advisory capacity in connection with the improvement of local transportation facilities. An attempt will be made, in coöperation with the street-railway company, for an operative service standard, for scientific rerouting in the terminal district and for progressive rehabilitation of the property. Mr. Bibbins was Resident Engineer for Mr. Arnold on the investigation of transit problems in Providence and San Francisco.

Mr. Joseph Bucklin Bishop, Secretary of the Isthmian Canal Commission since September, 1905, has resigned, as his work at Panama has been completed. Mr. Bishop founded and edited the "Canal Record," and is well known to many engineer visitors to the Canal Zone. Previous to entering the Canal Service he was for 35 years engaged in newspaper work in New York City, chiefly as an editorial writer with the "Tribune" and the "Evening Post." Mr. Bishop has entered a contract with Charles Scribner's Sons, publishers, New York City, for literary work in connection with their magazine and publication department.

Mr. Etienne Pelland, former Engineer in charge of the sewer department of Montreal, Que., has been arrested on charges of alleged graft in connection with the construction of the Notre Dame de Grace sewer. According to the Montreal "Gazette,"

> It is alleged that during the period between January and April, 1911, with intent to defraud the city of Montreal by false pretences, Mr. Pelland illegally, unlawfully and fraudulently procured, and caused to be procured at various times, various sums of money, in all amounting to about $75,000, to various persons, by making false reports and causing to be made false plans and profiles of a sewer to falsely and fraudulently represent rock at certain elevations.

Mr. George M. Lehman, M. Am. Soc. C. E., Engineer in Charge of the Pittsburgh Flood Commission work, Pittsburgh, Penn., has been appointed Chief Engineer of the Lake Erie & Ohio Canal Board, recently appointed by Gov. Tener,

of Pennsylvania. The members of the Board are: President, Mr. William A. Magee, former Mayor of Pittsburgh; Col. Thomas W. Symons, Corps of Engineers, U. S. A., retired; Mr. Tom P. Smith, of Lock No. 4, Washington County, Penn.; Messrs. James A. Chambers and A. S. McSwigan, of Pittsburgh, Penn. Offices have been opened in the Farmers Bank Bldg., Pittsburgh, and the fieldwork of surveying has been begun.

Messrs. George T. Seabury and Albert A. Northrop, M's Am. Soc. C. E., announce the formation of the firm of Seabury & Northrop, Inc., Consulting and Construction Engineers, 101 Park Ave., New York City. Mr. Seabury is a graduate of the Massachusetts Institute of Technology, class of 1902, and received his early engineering experience with the contracting firms of J. C. Rodgers and John F. O'Rourke. For the past eight years he has been connected with the Board of Water Supply of the City of New York, engaged upon the preliminary investigations of the Olive Bridge dam, later as one of the two personal Assistants to the Chief Engineer, and for the last four years as Assistant to the Division Engineer, in charge of constructing the Kensico dam and that portion of the Catskill aqueduct, including the complicated Control Works at the Kensico reservoir. Mr. Northrop is a graduate of New York University, class of 1900, and his early experience was in railroad construction and maintenance. He was in direct charge of the construction of the Olive Bridge dam of the Ashokan reservoir for the Board of Water Supply, and for the last four years has been associated with Mr. John R. Freeman, M. Am. Soc. C. E., Consulting Engineer, of Providence, R. I. For Mr. Freeman, he has had charge of the construction of the Holter dam across the Missouri, in Montana, of estimates and reports upon the various hydro-electric developments, and was Auditing Engineer on the construction of the hydraulic features of the Mississippi River Power Co., at Keokuk, Iowa. The new firm will specialize in the investigation of hydroelectric developments and the supervision of general construction.

Mr. Alfred Douglas Flinn, M. Am. Soc. C. E., Department Engineer of the Board of Water Supply of the City of New York, has been promoted to be Deputy Chief Engineer, succeeding Mr. Merritt H. Smith, M. Am. Soc. C. E., resigned, to become Chief Engineer of the Department of Water Supply, Gas and Electricity, as noted in our personal columns of July 9. Mr. Flinn was born in Pennsylvania in 1869 and graduated in civil engineering at the Worcester Polytechnic Institute in 1893. From 1893 to 1895 he was connected with the distribution department of the Boston, Mass., waterworks, under Mr. Dexter Brackett, M. Am. Soc. C. E., Chief Engineer. From August, 1895, until October, 1902, Mr. Flinn was with the Metropolitan Water Commission of Boston, first as a transitman and Assistant Engineer on surveys, and later on design and construction of various parts of the Metropolitan water-works. From 1902 to 1904 he was Managing Editor of the "Engineering Record." Mr. Flinn first became connected with the New York City water-works in August, 1904, as General Inspector of the Croton Aqueduct Commission. On the establishment of the Board of Water Supply's engineering department in 1905, to make and carry out plans for the Catskill water supply, Mr. Flinn was appointed Department Engineer in charge of the headquarters department, where he had supervision of the preparation of all important designs, the preparation of contracts and specifications, the inspection of materials, researches and investigations, annual and other reports, organization and general executive matters relating to the engineering bureau. The appointment is effective Aug. 1 and carries a salary of [illegible] per annum.

OBITUARY

[illegible], former Minister of Railways and Canals of Canada, died July 9 at his home in [illegible], N. B.

[illegible], a civil engineer employed by the sewer department of Toronto, Ont., was asphyxiated by illuminating gas while making survey measurements in the [illegible] St. sewer tunnel, Toronto, July 7.

[illegible], for many years Professor of [illegible] at the Brooklyn Polytechnic Institute, died July [illegible], at his home in Brooklyn, N. Y. He was born in 18[illegible]; he retired from the faculty of the Institute in 18[illegible].

[illegible], for many years Chief Engineer of the [illegible] Coal [illegible] Co., died July [illegible], at the home of his son, George [illegible], a contractor of Brooklyn, N. Y. The elder Mr. [illegible] was born in England [illegible] years ago.

Samuel F. Prince, Jr., formerly Superintendent of motive power and rolling equipment of the Philadelphia & Reading Ry., died in New York City, July 13. He resigned from the railway company in 19[illegible]4 to accept a position with the Niles-Bement-Pond Co., New York City. He was 62 years old.

Kurt W. Peuckert, of the firm of Peuckert & Wunder, Architects and Engineers, Philadelphia, Penn., died July 11, at his home at Sharon Hill, Penn. He was born in Germany 68 years ago, and came to this country at an early age. He was a member of the Franklin Institute and many fraternal societies. He is survived by a widow and one daughter.

Dr. William Bleecker Potter, M. Am. Inst. M. E., Mining Engineer and Metallurgist, founder and Manager of the St. Louis Sampling & Testing Works, St. Louis, Mo., died July 14, aged 68 years. He was a son of Bishop Horatio Potter and a nephew of the late Bishop Henry C. Potter, of New York City. He was born at Schenectady, N. Y., in 1846, and graduated from Columbia University in 1866. In 1869 he received the degree of Mining Engineer at Columbia. For a few years he was Assistant in geology at Columbia, and then was Professor of mining and metallurgy at Washington University, St. Louis, Mo., until 1893, when he founded the St. Louis Sampling & Testing Works.

ENGINEERING SOCIETIES

COMING MEETINGS

AMERICAN ASSOCIATION OF RAILROAD SUPERINTENDENTS.
Aug. 20-21. Annual meeting in New York City. Secy., E. H. Harman, Room 101, Union Station, St. Louis, Mo.

AMERICAN PEAT SOCIETY.
Aug. 20-22. Annual meeting at Duluth, Minn. Secy., Julius Bordollo, 17 Battery Place, New York City.

AMERICAN BOILER MANUFACTURERS' ASSOCIATION.
Sept. 1-4. Annual convention in New York City. Secy., J. D. Farasey, E. 37th St., and Erie Ry., Cleveland, Ohio.

AMERICAN MINE SAFETY ASSOCIATION.
Sept. 7-10. Annual meeting in New York City. Secy., H. M. Wilson, Bureau of Mines, Pittsburgh, Penn.

NATIONAL ASSOCIATION OF PORT AUTHORITIES.
Sept. 8-10. Annual convention in Baltimore, Md. Secy., Wm. Joshua Barney, 29 Broadway, New York City.

ROADMASTERS AND MAINTENANCE OF WAY ASSOCIATION OF AMERICA.
Sept. 8-11. Annual meeting at Chicago, Ill. Secy., L. C. Ryan, Sterling, Ill.

MASTER CAR AND LOCOMOTIVE PAINTERS' ASSOCIATION.
Sept. 8-11. Annual convention in Nashville, Tenn. Secy., A. P. Dane, Reading, Mass.

NEW ENGLAND WATER-WORKS ASSOCIATION.
Sept. 9-11. Annual convention in Boston, Mass. Secy., Willard Kent, Narragansett Pier, R. I.

INTERNATIONAL ASSOCIATION OF MUNICIPAL ELECTRICIANS.
Sept. 15-18. Convention in Atlantic City, N. J. Secy., Clayton W. Pike, Electrical Bureau, Philadelphia, Penn.

ILLUMINATING ENGINEERING SOCIETY.
Sept. 21-2[illegible]. Annual convention in Cleveland, Ohio. Secy., Joseph D. Israel, 29 W. 39th St., New York City.

RAILWAY SIGNAL ASSOCIATION.
Sept. [illegible]-24. Annual convention in Bluff Point, N. Y. Secy., C. C. Rosenberg, Times Building, Bethlehem, Penn.

American Society of Agricultural Engineers.—The committee on farm structures of the American Society of Agricultural Engineers, the chairman of which is E. S. Fowler, Security Bank Bldg., Minneapolis, Minn., is making a study of the most economical and convenient designs for farm buildings, etc. The results of the study will be reported at the next convention of the Society, to be held in Chicago, next December.

American Boiler Manufacturers' Association.—The 26th annual convention will be held in New York City, Sept. 1-4, with headquarters at the Waldorf Astoria Hotel. All boiler, tank, and stack manufacturers and fabricators of steel plates, also manufacturers of materials and supplies used by boiler manufacturers are invited to attend this convention. Among the important subjects to be discussed is that of uniform boiler specifications. The secretary is F. B. Slocum, West and Calyer Sts., Brooklyn, N. Y.

International Street Railway and Light Railway Congress.—The next meeting will be held at Budapest, Austro-Hungary, Sept. [illegible] to 1[illegible], instead of in August as previously announced. In addition to entertainments during the period of the Congress there will be two alternative excursions of three days each. One of these is north to Tatra in the Carpathian mountains, the other is south to Arad and Baziás, and thence by steamer down the Danube to [illegible]. The Secretary of the Congress is H. [illegible]amp, 21 Rue d'Arlon, Brussels.

Engineering News

VOLUME 72 JULY 30, 1914 NUMBER 5

Framework of the Equitable Building

Steel erection recently began on what will be the largest office-building in existence, the Equitable Building, New York City, on the site of the burned office-building of the Equitable Life Assurance Society.* The large size is the product of an unusual area of ground plan and an unusual (but not unprecedented) height. But it must be remembered that the very tall buildings, as the Singer, Metropolitan, Central Union, L. C. Smith, and Woolworth, are tower buildings, the main buildings being of moderate height and only a narrow section or tower extending up beyond this. The Equitable, on the other hand, represents a reversion to the normal type of building, the ground-plan area being carried up undiminished to the top. In part this may be due to the fact that it occupies an entire block (Broadway to Nassau St., Pine St. to Cedar St.) over which the old Equitable Building spread in its heterogeneous growth.

*For notes on the fire of Jan. 9, 1912, and the old building, see "Engineering News," Jan. 18, 1912, p. 123, and Nov. 28, 1912, p. 986.

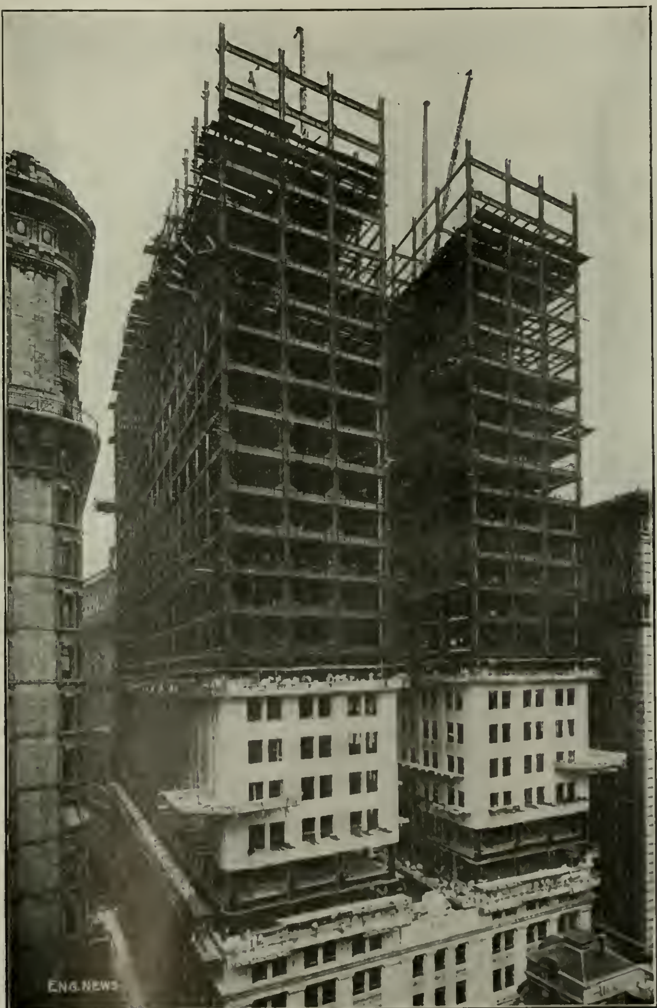

Fig. 1. The Equitable Building on July 16, 1914

Structurally the building is of remarkably regular design. All its columns run through from footing to roof, and there are no trusses or similar complications—an unusual condition in so large a building. The frame is composed essentially of columns, beams and wind-bracing.

The bank vaults in the basement, as well as engines and boilers, etc., are carried on their own foundations, independent of the steelwork, thus eliminating the weight of framing which would have been required to support them.

The Equitable has three stories below ground and 36 main stories above, but these contain two intermediate floors (3 to 4, 34 to 35), making 41 tiers of beams, inclusive of the roof. The building is about 542 ft. high from Broadway sidewalk to coping; measured from the level of the normal foundation grillages, it is about 600 ft. high.

The area of the block occupied by the building is slightly more than an acre, being 159 ft. in width average and 308 ft. in length average (the outline of the block has no right angles and no parallel lines). Thus the total floor space is nearly 40 acres.

Great Weight of Framework

While ordinary office-building floor loads are figured on in the design of the building, the mere size of the structure makes the weight of the framework run to unprecedented figures. The following little tabulation is instructive:

WEIGHT OF STEEL FRAMEWORK IN SOME LARGE BUILDINGS

Equitable Building, New York	32,000
[illegible], Philadelphia	28,000
Woolworth, New York	26,000
Hudson Terminal, New York	20,000
Continental National Bank, Chicago	16,000

There are several buildings in the neighborhood of 20,000 tons of steel. It is seen that the Equitable Building is from 1[illegible] to 14% in excess of what has heretofore been attained in office-building construction, in point of size as gaged by weight of frame.

and this section is developed to areas of over 390 sq.in., about twice as great an area as ever before used with this form of column.

General Arrangement

The floor plan (see windbracing sheet) shows that the building is arranged in H-form, courts being cut in at the middle of the Nassau St. and Broadway fronts, each 35 ft. wide and about 77 ft. deep; these courts, however, exist only above the sixth floor. The floor area within outer walls is 45,000 sq.ft. per floor below the sixth, and 40,000 sq.ft. above.

The elevators are in six banks of eight each, in the center of the building, extending to the following floors, respectively: 13th, 21st, 28th, 33rd, 36th and 38th. In

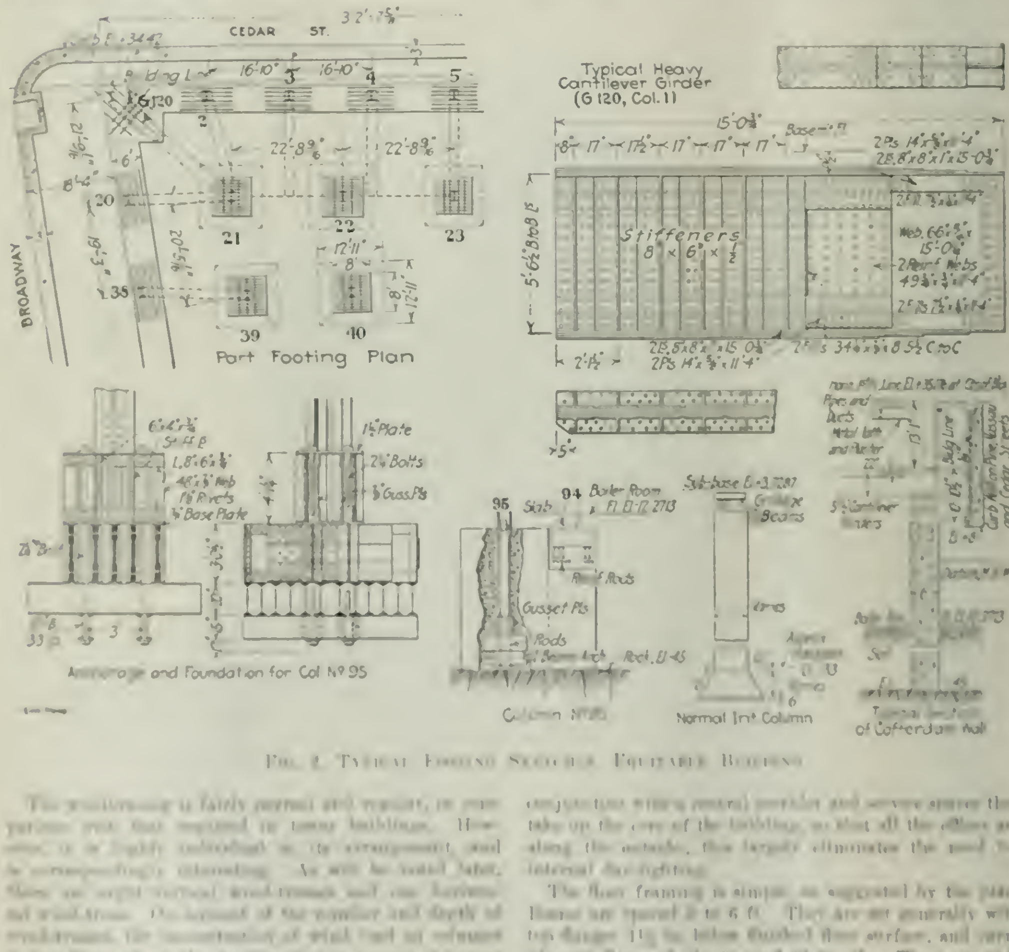

Fig. 2. Typical Footing Sketches, Equitable Building

The windbracing is fairly normal and regular, in comparison with that required in many buildings. However, it is highly individual in its arrangement, and is correspondingly interesting. As will be noted later, there are eight vertical wind-frames and one horizontal wind-truss. On account of the number and depth of windframes, the concentration of wind load on columns is less than where the windbracing is [illegible] concentrated. Therefore, while the Equitable has some remarkably heavy column sections, none of these are [illegible]. [illegible] however, is [illegible] for [illegible] heavy construction; a simple I-section is used.

[illegible] with a central corridor and service spaces that take up the core of the building, so that all the offices are along the outside, this largely eliminates the need for interior daylighting.

The floor framing is simple, as suggested by the plan. Beams are spaced 5 to 6 ft. They are set generally with top flange 1½ in. below finished floor surface, and carry tile-arch floors of 12, 14 and 16 in. tile. These are end-construction flat arches, with [illegible] —the latter an unusual feature.

The wall architecture is also sufficiently regular to make the connections of the steelwork at the walls rela-

tively simple. A few spandrel sections are illustrated in Fig. 5.

Foundations

In the original design, most of the piers for the interior columns were to be carried only to the hardpan overlying the rock (as shown in Fig. 2). Before the piers were built, however, it was decided to carry them down to rock. All these piers were built in open pits.

The entire exterior line of columns is carried on *pneumatic caissons* sunk to rock, and these caissons are arranged to form a tight coffer-dam wall, retaining the surrounding earth and excluding water. The steelwork of basement and sub-basement floors braces this coffer-dam wall.

Four of the interior column piers are specially heavy, and contain steel anchorages. These are the main piers of the principal central windbracing system (systems *C*, windbracing sheet), being cols. 44, 47, 92 and 95. A general sketch of one of these piers is given in Fig. 2. Alongside is a sketch of one of the normal interior foundations.

The section through the coffer-dam wall and curb retaining wall in Fig. 2 illustrates the foundation arrangements at the street line.

In connection with the foundations it is to be noted that the present practice of the Building Department in New York City prohibits foundations extending beyond the building line into the clearway of the public streets. This means that the outer edges of the grillage footings must be inside the building line and the center of the footing therefore some distance back of the building line. As the column ordinarily will not be so far back of the building line, cantilever footings must be used in order to center the load on the grillage. Thus the entire outer ring of column bays in the building contains cantilever footing girders. At the corners of the building the cantilever girders of the corner column and the two adjoining wall columns were carried back to the same interior column for anchorage. This results in a three-forked girder arrangement at the corners, as shown by sketch in Fig. 2.

At the four main columns of the central windbracing system, the wind stress exceeds the dead-load at top of concrete pier, giving an uplift on the windward side. For this reason the column base is anchored and a special connection of base to column provided to transmit the tension; and the splices in the lower section are proportioned to transmit the tension.

The concrete caps of all foundation piers, under the column-footing grillage, are reinforced by two layers of steel rods in the concrete, although the grillage beams cover the entire area of the pier.

The I-Shaped Columns

Strict uniformity was maintained in the column design, all sections adhering to a set of three types, namely:

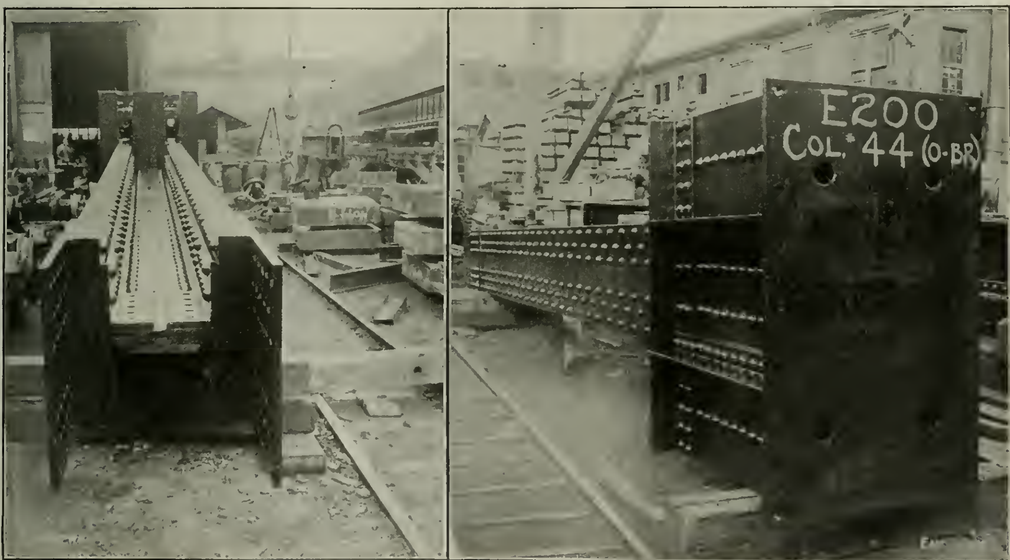

FIG. 3. AN ANCHOR COLUMN OF THE EQUITABLE BUILDING, IN THE PENCOYD SHOP YARD

(American Bridge Co.)

Simple I-section, consisting of four angles and web: I-section with covers; and I-section with covers and web reinforcing. However, there were three fixed depths of web (13, 14 and 17 in.), and three widths of cover-plate (18, 20 and 24 in.), so that 13 separate series of column sections resulted. The following remarks on the several classes begin with the lightest (upper stories) and go downward:

SIMPLE I-SECTION—Classes A, B and C, of web depth 13 in., 14 in. and 17 in., respectively. Range of make-up, from four angles 5x3x⅜-in. with ⅜-in web, to four angles 8x8x$\frac{15}{16}$ in., with $\frac{13}{16}$-in. web. Range of area, 17 to 72 sq.in.

I-SECTION WITH 18-IN. COVERS—Classes D, E and F. Body, four angles 8x6 or 8x8x⅞, with ⅞-in. web; cover-plate thickness per flange, from [illegible] in. to 2 in. Range of area, 69 to 139 sq.in.

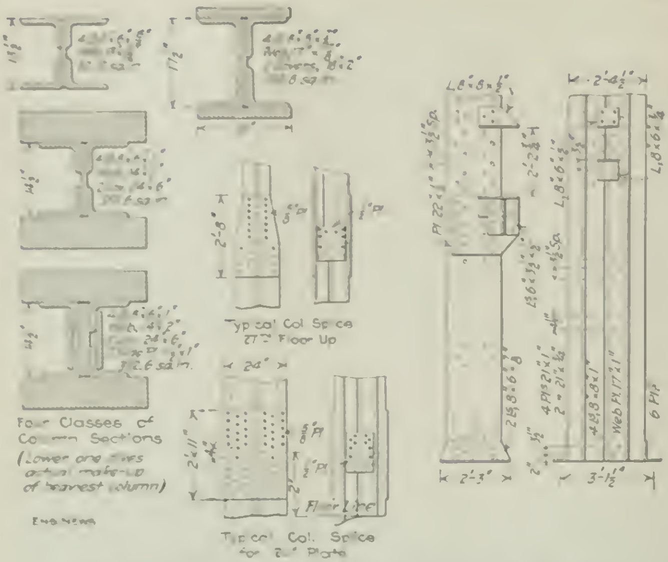

FIG. 4. TYPES OF COLUMN SECTION, EQUITABLE BUILDING

I-SECTION WITH 24-IN. COVERS—Classes J and K (14- and 17-in. web). Body, four angles 8x8x1 in., with 1-in. web, cover-plate thickness per flange, 2½ in. to 6 in. Range of area, [illegible] sq.in. to 356 sq.in.

I-SECTION WITH SIDE PLATES—Class M (14-in. web). Body, [illegible] web 14x1 in. to 14x2 in.; two side plates, [illegible]x1 in.; cover-plates per flange, 24x6 in. Range of area 373 to [illegible] sq.in.

The thicknesses of cover-plates, etc., refer in all cases to total thickness specified. It was left to the contractor to decide upon the number of the plates with which to form this thickness. For the thick covers, 1-in. plates were generally used, partly because more readily obtainable in long lengths, and of more assured quality, than thicker plates.

Four sizes of rivets were used in the columns, as well as elsewhere in the work: ¾-in. rivets for grips of less than 2 in.; ⅞-in. for grips from 2 in. up to 4 in.; 1-in. rivets for grips of 4 in. to 6 in.; and 1⅛-in. rivets for grips of 6 in. and over.

A set of type sections of columns and an actual cross-section of the maximum column are given in Fig. 4.

The column of greatest sectional area, [illegible] sq.in., has a length of 11 ft. [illegible] in., and weighs [illegible] tons. Its maximum load is [illegible] tons. Another column weighs more, however, on account of its greater length ([illegible] ft. [illegible] in.). Its weight is [illegible] tons. The longest column section, 47 ft. long, weighs [illegible] tons. The character of the detailing and riveting is shown in Fig. 4 by a copy of the shop drawing for one of the heavy columns, and in Fig. [illegible] a view of one of the [illegible] column sections.

[illegible] are interposed between column and grillage.

WINDBRACING

The end areas being small and the resisting sides (east and west) being very long, no special provision is made for windbracing on the long north and south fronts of the building. All spandrel girders on these two sides, however, have top and bottom connections as well as web connections to the columns, and therefore offer ample resistance to pressure in a longitudinal direction.

In the shorter or transverse (north and south) direction, where the total width of the building is about half the length and where the width of the wings alongside the courts is about one-sixth the length, there are no less than eight planes of windbracing (see plan on windbracing sheet). Each plane was designed to support the building halfway to the adjoining plane of bracing on either side.

The planes of bracing are as follows: One each in the Broadway and Nassau St. fronts; one each in the back walls of the courts (systems *A* and *A*[1]); and four lines between the A-systems, namely systems *B*, *C*, *C*[1] and *B*[1]. The front and A-systems extend the full width of the building, except that the former are divided by the courts which extend above the sixth floor. The B- and C-systems, however, are confined to the three center panels of the width, where they do not infringe on office space. Therefore the windbracing problem in the middle part of the building was just as serious as in a very much narrower building of the same height.

Further, the B- and C-systems are not entirely equivalent, for the C-systems, forming the central bracing, extend to the 32nd floor, while the B-systems go up only to the 23rd floor. Above the 23rd floor the C-system must carry the entire building between back walls of courts, a length of about 150 ft. At the 23rd floor, therefore, where the B-systems start and the A-systems broaden from the width of the wings to the full width of the building, a horizontal truss is formed in the floor, tying together systems *B* and *C*. At this level the wind shear of the C-systems is assumed to divide equally between the B's and the C's, but, of course, the accumulated column wind stress in the C-systems remains there.

The front wall system and A-system of wind bracing are made up almost exclusively of girders and gussets or knee-braces. The four interior B and C windbracing systems have girder bracing in the center panel, the outside panels having diagonal bracing. Girders with gussets are used in the middle panel for the reason that this panel must be left unobstructed for corridors (wind-

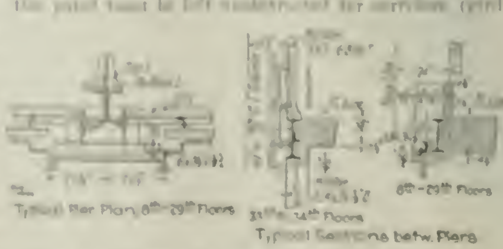

FIG. 5. TYPICAL SPANDREL SECTIONS, EQUITABLE BUILDING

ers and gussets are also used in some special cases in the side panels of the B-system). Up to the 13th floor, double girders and gussets are used, for the reason that with single-girder construction the girders would have been so deep as to infringe on the headroom of the corridors. Single girders and gussets are used from the 14th floor upward.

In the upper floors the diagonal bracing of the B- and C-systems is in panels two stories high. In the three lower stories the diagonal system is one story high, with intermediate horizontal struts run from the point of intersection of the bracing to the point of counterflection of the columns next to the corridors.

The two main fronts, on Broadway and Nassau St., have large entrances two stories high. The high unsupported lengths of the columns at these points are reinforced by auxiliary columns, with diagonal windbracing between the two.

Except in the 23rd floor, no interior horizontal floor bracing is used, the floor construction itself being relied upon to transfer by shear in each floor the wind pressure from panel to panel and finally to the exterior or interior vertical windbracing systems.

Typical details of the windbracing are shown on the windbracing sheet. The proportioning of the diagonals will be obvious. The knee-braced wind girders range generally from 24- to 42-in. depth, with webs generally from $\frac{5}{16}$ to ½ in. thick though some are as thick as $\frac{11}{16}$ in. The flange angles are 6x3½ in. or 6x6 in., in thickness from ⅜ in. to ⅞ in. These ranges of dimensions may be taken as increasing quite regularly from the 32nd floor to the bottom, the lowest values applying to the upper five or six stories of windbracing.

Design of Windbracing

The wind pressure was assumed at 30 lb. per sq.ft. over the entire surface of the building from sidewalk to coping, in accordance with the New York building code. The method of analysis of wind stresses is substantially the same as has been followed in a considerable number of large buildings.

The fundamental assumptions were: (1) Points of contraflexure of columns and girders are at mid-span and mid-height, respectively; and (2) column reactions vary as the distance from the neutral axis of the group. The principle of the method, strictly, requires that the column reactions should be proportional to the products of sectional area and distance from neutral axis. But for simplicity it was assumed that all columns are of equal area; that is, the wind reaction attributed to a particular column of a bent depended only on its distance from the neutral axis of the bent and not upon its area as compared with the areas of other column sections in the bent.

The vertical shears in the panels of a bent for a given story accumulate toward the neutral axis. These shears represent the increment of the column reactions of that story; hence the vertical shear in the center panel is equal to all the column reaction increments on one side of the neutral axis.

The horizontal shears in the columns of a bent increase toward the neutral axis, and represent the forces required to balance the action of the vertical shears in the panels acting on any one joint.

To facilitate calculations in a system of more than three columns, the effective depth is first established. This effective depth is equal to the distance between resultants, which are located at the center of gravity of the column reactions on each side of the neutral axis of the system. The value of these resultants is 100%, while the percentage value of any one column varies according to its distance from the neutral axis.

This cantilever method was adopted some years ago by the engineering department of Graham, Burnham & Co., in charge of J. G. Giaver. It is now used in figuring wind stress in all tall buildings designed by this firm. In the earlier period of high-building construction, the engineers commonly considered only horizontal shears produced by the wind pressure.

Detail Procedure—The procedure in applying this method was as follows: Taking a given plane of windbracing, for instance, one side of the Broadway front, the effective depth of this "wind-truss" was computed, i.e., the distance from center line of bent to the line at which the aggregate actual tensions and compressions in the columns would give the same resisting moment. In this case, the bent being 62.6 ft. wide, the effective depth was found to be 52.4 ft. Denoting by 100% the chord stress, which would result in each of the two chords of a truss of this effective depth, the percentages of wind reaction in the several columns of the actual bent were found. These percentages, being constant at all floors, hold good for the entire bent, so long as its dimensions did not change.

Second, the wind shear generated at each floor level of the bent was computed, and by the successive addition of these shear increments, the total wind shear in each story was found. These shears, multiplied by the distance center to center of successive stories, gave the overturning moments in the several stories, which must be resisted by the column stresses. Dividing this moment by the effective depth of wind truss (as previously found) yielded the 100% chord-stress figure, which, upon multiplication by the percentages belonging to the different columns of the bent, yielded directly the column wind reactions.

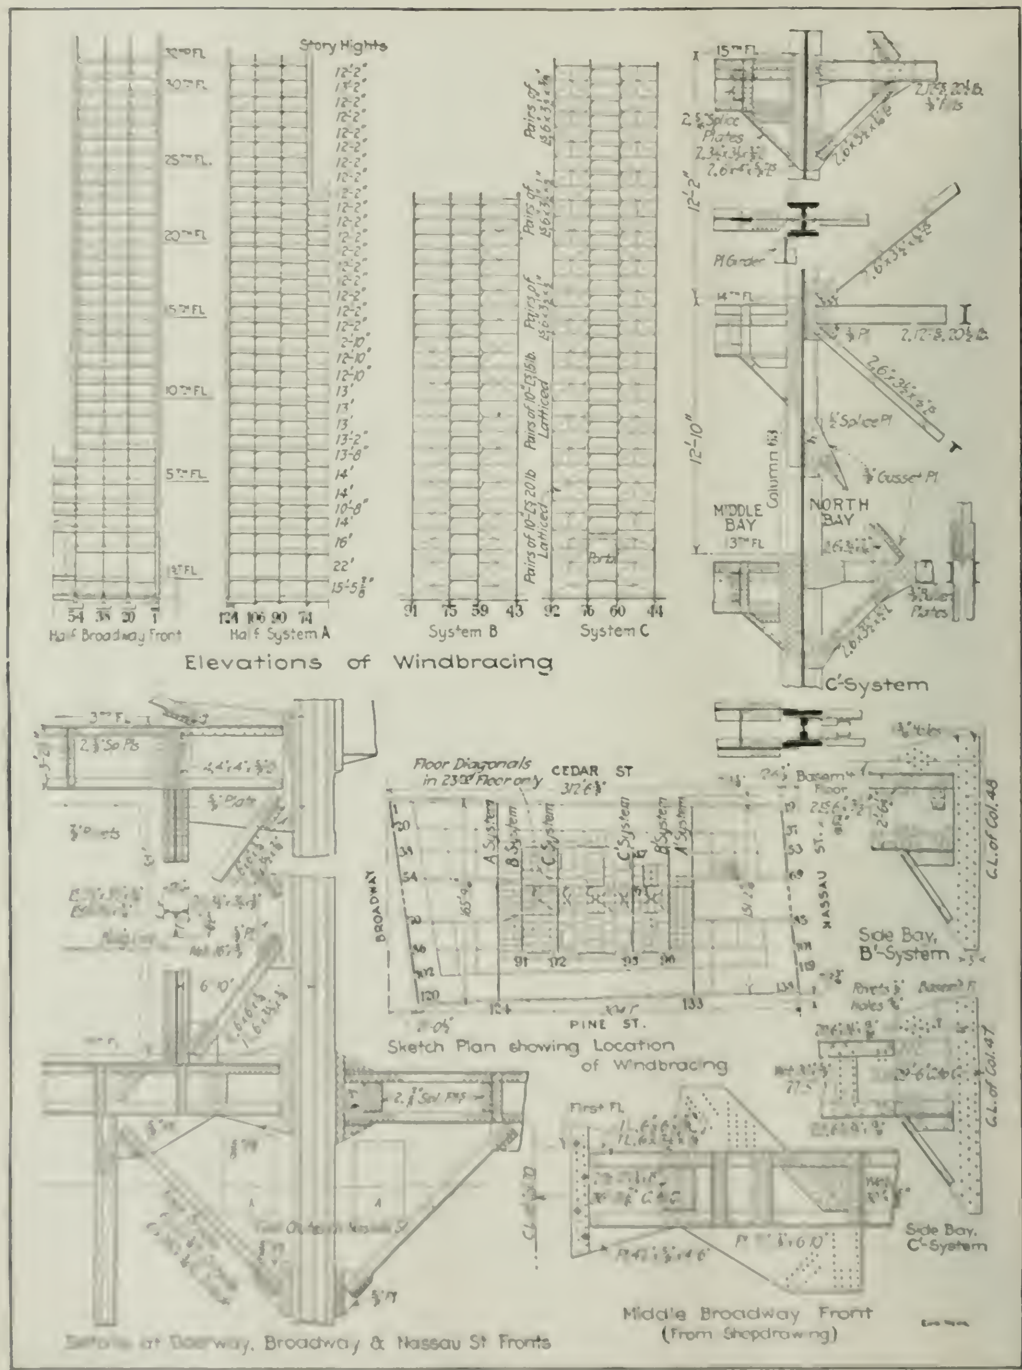
The distances between column stresses in successive stories gave the girder shears directly, and from the girder shears, by taking moments around the complete joint, the column shears were obtained.

The computation, according to the procedure outlined, proved to be well suited to convenient tabular work. In this entire analysis *the knee-braced bays were treated as though equivalent to the bays with diagonals.*

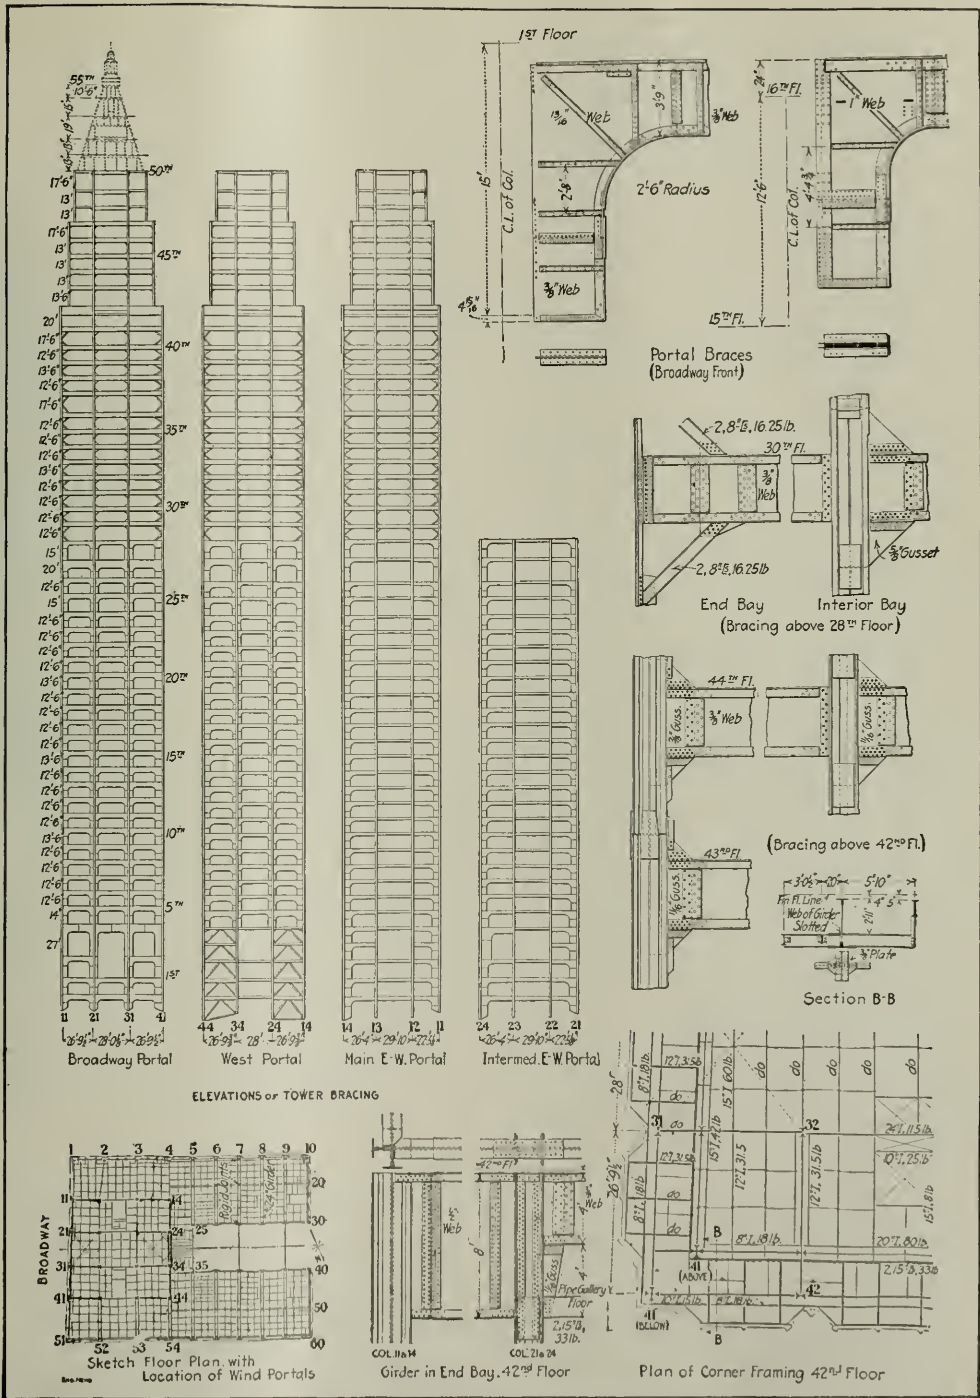
Designers and Builders

The Equitable Building was designed by E. R. Graham, architect, Chicago (Joachim G. Giaver, structural engineer). The Thompson-Starrett Co. (George Simpson, Chief Engineer), of New York, is general contractor for the building. The subcontract for furnishing the steel was let to the American Bridge Co., while the Thompson-Starrett Co. itself is erecting the steel (see Engineering News, Apr. 23, 1914).

The following article, on the windbracing of the Woolworth Building, facilitates direct comparison of the structural parts of the largest and the highest office buildings in the world. On pages 230 and 231 are given comparative windbracing drawings.



WINDBRACING OF THE EQUITABLE BUILDING



WINDBRACING OF THE WOOLWORTH BUILDING

(Plan and tower elevations are to same scale as on Equitable sheet).

Frame and Windbracing of Woolworth Building

The Woolworth Building, 233 Broadway, New York City, completed during the past year, is the tallest office building in the world, and the most prominent example of the tower type. Its general outlines are familiar but the character of the windbracing has received little attention. We outline it in the following, for comparison with the preceding account of the Equitable Building windbracing.

The Woolworth Building is 55 stories high and extends 7[illegible] ft. (base of flagpole) above curb. The main portion, however, is only 30 stories high, the upper half of the height consisting of a tower about 85 ft. square. From the windbracing standpoint the building is all tower, since the parts of the building outside of the tower are left entirely free of windbracing, the rearward wings excepted.

Great interest attaches to the bracing because of the thoroughgoing use of the portal system of bracing. This system has not been used extensively in windbraced buildings before this, whereas in the Woolworth Building it constitutes the principal or sole element of lateral strength of the building in the lower 27 stories. The upper portion of the building, involving lighter wind moments, is taken care of principally by girder-and-knee-brace stiffening.

The rear wings are braced independently of the forward half, which centers about the tower. The bracing of the wings is of the type first applied by S. C. Weiskopf in the Trinity Building, New York City, and subsequently adopted in a number of other structures* and today perhaps the most popular type, i.e., double-girder rigid-joint bracing without kneebraces. In this system, the regular floor girders are pairs of channels or I-beams (here, a pair of 24-in. plate girders) straddling the columns, and either the girders or splice-plates at their ends are riveted to the side faces of the columns, the shear moment of the rivet group being made sufficient to resist the girder wind-moment. The connection is developed wholly within the depth of the girder.

The two wings are made to act together by struts spanning the light-court. There are two struts at every fifth floor (see ground plan on inset sheet). No portal-girder action is counted on in these struts.

The arrangement of the tower bracing is shown by a series of elevations and a small-scale plan, on the full-page windbracing sheet herewith. (Both plan and elevations are to the same scale as those of the Equitable Building, on the page opposite.) The detail construction is typically represented by several larger-scale sketches.

Design of Wind Bracing

The basis for the calculation of wind stresses was a wind load of [illegible] lb. per sq.ft., which corresponds to the New York Building Code requirement of 30 lb. wind with [illegible]% stress increase.

The *column stresses* caused by wind were assumed to be proportional to the distances of the several columns from the center of gravity of the bent or plane of bracing to which the columns belong. The *column shears* were assumed to be equal, in any particular story of the bent. The *column contraflexure* was taken at midheight of the story. On the basis of these assumptions, the girder shears in the several bays of a story necessarily came out unequal, and the girder contraflexure was found to be not at the middle point of the bay (except in the central bay of the bent). The designers state that this method of calculation was used because it gives stresses slightly higher than those based on the assumption of unequal column shears (girder contraflexure at middle of bay).

In applying the method to the east-west planes of bracing in the tower, the easterly pair and westerly pair of portals were considered independent, joined simply by struts in the middle bay; in other words, the east-west bracing was regarded as consisting of eight independent two-column bents. This, of course, applies only below the 28th floor, as above this level the two intermediate planes of bracing are omitted, and the entire east-west tower bracing is in the northerly and southerly walls of the tower.

In constructing the portal bracing, the upper or horizontal part of the portal was built as a separate erection piece, in the shape of a girder. The vertical portions also were built as separate pieces, field-connected by vertical joints to the columns and by horizontal joints to the upper part of the portal. The columns in most cases were constructed with projecting web or flange plates, as gusset-strips for attaching the portal.

Columns

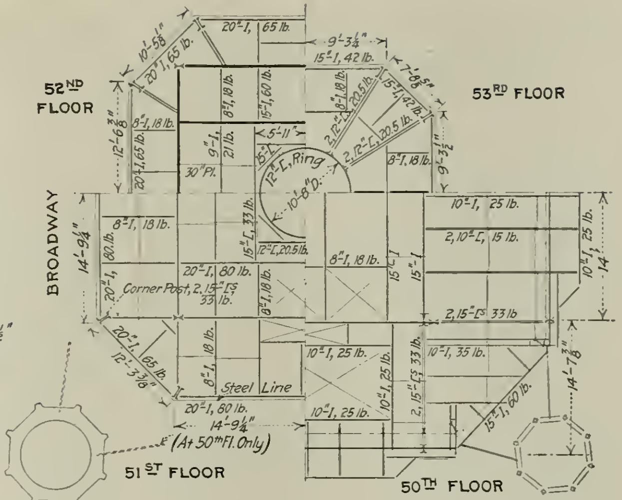
The building is notable for its heavy column sections. In fact, the heaviest columns far exceed any previously used in buildings. The maximum column has a cross-section of 700 sq.in. It is made of three webs, 21 in. deep, aggregating $12\frac{1}{4}$ in. in thickness; eight flange angles 6x6x$\frac{7}{8}$ in.; eight middle angles, 6x4x$\frac{7}{8}$ in., and two $43\frac{1}{2}$-in. cover-plates each of total thickness $3\frac{1}{2}$ in. In each cover-plate, one of the component plates is extended out $3\frac{1}{2}$ in. as a connection for the portal bracing. Similarly, a longitudinal connection plate 7x1 in. is riveted at right angles to the middle of one of the flange-plate faces by means of two 5x3x$\frac{1}{2}$-in. angles, as a connection for the other plane of portal bracing reaching this column. This column carries a maximum total load of about 4740 tons, of which 1300 tons is wind load.

The same type of column was generally used in the lower portion of the building; that is, three built up webs and two cover-plates, forming a two-cell box column. All columns are made in two-story lengths.

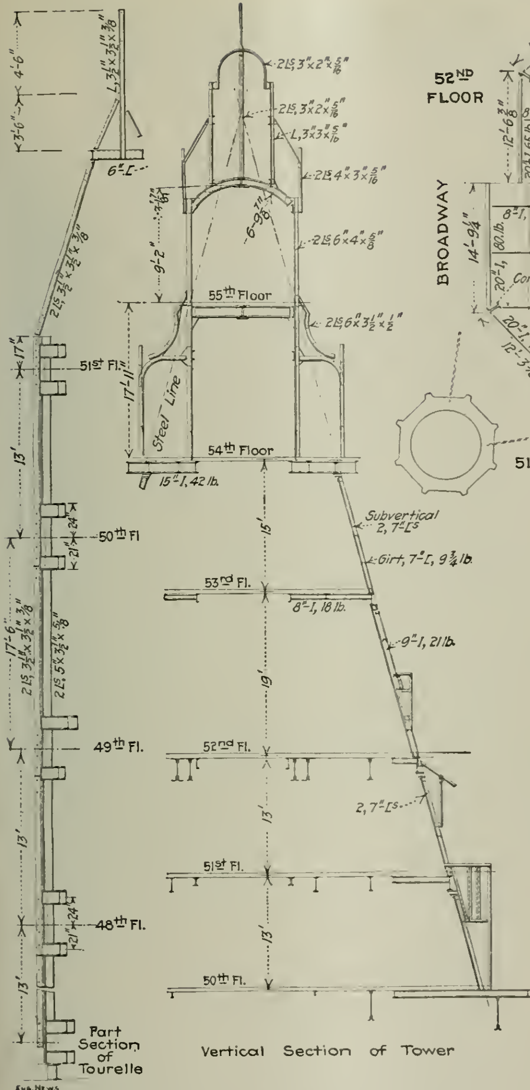
Special Framing

The architectural development of the Woolworth tower called for setting back the wall line several feet at the 42d and 47th floor levels. At each of these points, the wall columns above do not have direct column support below, but must be carried by girders. This arrangement is typically represented on the windbracing sheet by a diagram of the girder-and-beam framing in one corner of the 42nd floor. Adjoining it is an elevation sketch of one of the heaviest of these girders, namely, that in the Broadway front, an 8-ft. plate-girder which supports the end of another girder on which the 42nd-story corner column is carried.

*[illegible]



TOWER FLOOR PLAN



TOWER FRAMING, WOOLWORTH BUILDING

Where the columns are thus offset, the transfer of wind shear in the outer faces of the tower must be made by way of the floor. The middle bay of the floor on each side of the tower has horizontal diagonals; for the rest the strength of the floor is counted on.

Corner turrets occur on the terraces where the walls are offset; those in the 42nd story are low, while those rising from the 47th floor are about 75 ft. high. Both have steel frame, supported upon and anchored to the floor steelwork. A vertical section through the larger turret is shown herewith. The northeasterly turret at this level is not steel-frame filigree work, but is a hollow brick shaft, which in external appearance is made as near like the other three turrets as possible. It is the chimney.

The tower framing is indicated by the composite plan and the vertical section herewith. The taper of the tower naturally changes the floor framing continuously, beginning at the 50th floor.

The steel framework of the Woolworth Building weighs 24,100 tons, which cost 1¼ million dollars. The building was designed by Cass Gilbert, architect, and built by the Thompson-Starrett Co., New York City. The steelwork was designed by the Gunvald Aus Co. and fabricated by the American Bridge Co.

The substructure, built by the Foundation Co. after the design of the Gunvald Aus Co., consists of concrete piers sunk by the pneumatic process to rock about 100 ft. below curb. The principal complication in the foundation work arose from the fact that the entire plan of the building was changed after the foundations were already started. The original plan was to build on the northerly (Park Place) side of the lot only, an area 102 ft. wide on Broadway by 197 ft. deep on Park Place, and contracts were let for the building designed to cover this site. Subsequently, the south half of the block, the Barclay St. corner, was bought and the building redesigned to cover the entire block of the Broadway front, with the tower in the center of this front. As the heavy columns, namely, those of the tower, were thus changed in location, the caissons had to be rearranged, and in some cases, where the proper arrangement was no longer possible, a combination of two caissons had to be used in place of one large caisson, and the columns supported by heavy triple girders spanning the two caissons.

The Total Value of the Mica produced in the United States in 1913 was $436,060. The production came from 11 states—North Carolina, New Hampshire, Idaho, New Mexico, South Dakota, South Carolina, Alabama, Virginia, Pennsylvania, Colorado, and New York, named in the order of the value of their output. The value of the production of mica in 1913 exceeded by $104,164 that of 1912, and was the largest ever reported.

Government Aid to Irrigation in the United States and in Australia

By Elwood Mead*

SYNOPSIS—In continuation of the discussion of "What Is the Matter with Irrigation," begun in the editorial columns of our issue of June 12, 1913, the author first pictures conditions in the United States which make farm ownership by the actual cultivators of the soil difficult in both unirrigated and irrigated areas, and particularly in the latter. The argument for State aid to irrigation farmers in the United States is supported by the practice and results in Australia, notably in the State of Victoria.

"The Answer to What Is the Matter with Irrigation?" contributed by E. P. Osgood to Engineering News, of Feb. 19, 1914, deals with obstacles to rural development in America that are encountered outside of irrigation areas.

Every increase in the price of land limits the numbers of those able to buy it. Farming land in some of the Western States now sells for five times as much as it did 10 years ago. Farms can be purchased within 30 miles of London at lower prices per acre, with less interest and better terms of payment, than is needed to buy farm land in parts of the Middle West. The result is that farm buying, in these localities, is now largely restricted to men with accumulated capital, while nonresident ownership and tenant farming are rapidly extending.

These are not desirable conditions, but if they are to be improved, it would seem that this country should bring into operation some of the agencies that are proving so effective in Europe, for enabling poor men to own the land they cultivate. The use of the credit and direction of the government in the buying and subdivision of land, the loaning of money to buy and improve farms on long-time payments, at less than half the rate of interest paid by farmers in Western America, are aids to the extension of agriculture and improvement of rural life now employed by nearly every civilized country excepting the United States, and they are as much needed in this country as in Ireland, if the United States is to continue to be a land of opportunity for farmers without capital.

The systems that restrict farm buying in the fertile East are delaying development in the irrigated West. The opportunities to build small, simple ditches and fill them from the mountain streams, without storage, are all absorbed. Large and costly canals, with reservoirs, to supplement the summer flow of streams, must now be built if irrigation is to extend. These mean costlier water-rights and larger annual operating charges, which must be paid in money instead of labor, as was formerly possible.

So long as there was public land to be had for the filing fee, and the cost of water-rights did not exceed $15 an acre, it was not difficult for a settler to bring enough land under cultivation to provide a living for his family and earn money to meet the payments on water-rights by working at intervals for others. Under these conditions it did not mean disaster if the improvements of the homestead was slow, as was almost invariably the case. But when larger canals had to be built and more difficult engineering obstacles overcome, and water-rights began to cost from $40 to $50 an acre, it was necessary, in order to meet the payments on these water-rights, for the settler to bring the whole of his land promptly under cultivation. To do this, he must expend about $30 an acre on clearing, grading and seeding, and about $40 an acre for a house, farm buildings and fences. He begins his attempt, therefore, saddled with a debt of about $100 an acre, and if the money for these improvements has to be borrowed in the West, it can only be obtained on comparatively short time and at a rate of interest much higher than that prevailing in many other countries with less available capital. It is no longer possible, therefore, for settlers, without capital, to support their families and meet the required payments, and it is not surprising that fully 80% of those who do attempt this, fail.

The obstacles to irrigation settlement, described in Mr. Osgood's article, are becoming more serious each year, and the prospects of failure to settlers, with small capital, are so great and the hardships involved so severe, that the continuance of settlement of unimproved irrigation areas, without state aid, cannot longer be honestly encouraged.

To leave unchanged conditions which restrict settlement under government projects to men with from $4000 to $6000 capital would defeat one of the most worthy objects of the Reclamation Act. Men with this amount of money do not need to go West and help subdue the desert and the number who do this would be so small as to delay for years the full use of existing canals. What is needed is a carefully thought-out scheme of National or State aid, which will carry the settler through the years when the outlays for improvements are large and the returns from cultivation small.

The best place to inaugurate such a system would be under the National Reclamation works. The nation could use its savings' bank deposits for this purpose and thereby secure larger interest than is now paid by the banks, and largely increase the income from its canals. Such action, while an innovation in this country, is a common feature of irrigation development elsewhere. In the Australian States, where there are still large areas of public land which are practically free, the settlers are given financial aid to carry them over the lean years when they are improving their farms. Owing to the similarity of conditions there and in Western America, it is believed that the methods these States have adopted can be successfully employed here.

Such aid is a feature of irrigation settlement in every Australian State, as it is recognized that the outlay needed to bring unimproved irrigable land under cultivation is larger than is needed under rainfall. The most extensive application of this idea is found in the State of Victoria, where large areas have been purchased, subdi-

*University of California, Berkeley, Calif.; lately Chairman of the State Rivers and Water Supply Commission, Victoria, Australia; formerly Chief of Irrigation Investigations, U. S. Department of Agriculture, and before that, State Engineer of Wyoming.

vided and settled by men with too little capital to attempt to secure a home unaided. Under its scheme, men have succeeded who had not a dollar to start with and settlers with less than $1000 are more numerous than those with more than this sum, although oversea settlers with less than $1500 are not encouraged.

Knowing that these settlers must be helped and could not afford to lose time nor to make mistakes, the state worked out a plan for their management, as complete in its details as that of a corporate, private enterprise. In order to lessen their living expenses while securing a farm, the settlers are lodged in a state-managed rooming house where meals cost only 12c. and room and bed 20c. a day. They are shown the land available, by a responsible state officer, with no expenses for conveyances outside reduced railway fares. When the farm is selected, the state, if requested, builds a house for the settler, he having the choice of 14 different designs. When the settler selects his type of house, he pays a deposit, varying with the cost, and has twenty years in which to complete the payments. Some of these houses are built before the settler arrives. Where they are erected after the settler arrives, the state provides portable houses and tents to shelter the family, for a nominal weekly rental, so that in either case he goes to work at once. The state also grades and seeds one-fourth of each settler's holding. If desired, the settler pays only one-fifth the cost of this grading at once and has ten years in which to pay the remainder. At first all the grading work was done by the state, but now private contractors are doing much of the grading, but the state still pays four-fifths of the cost wherever it approves the contracts and accepts the completed work.

As a result of this assistance, many of the settlers who have gone into dairying have been getting cream checks which more than meet all living expenses in less than thirty days after selecting their farms. Even with this aid few settlers are able to bring the whole of their land into cultivation the first year. It usually requires two or three years to get the entire farm fenced, ditched, graded and seeded. During this development period the settler has a large outlay and less than full income and he would not be able to improve his land promptly unless further aid was extended. This is done by the state loaning the settler money on his improvements. Ditches, fences, grading of land, erection of buildings and the planting of orchards and vineyards are improvements entitling the settler to loans. The state values these improvements and lends up to 60% of the valuation. Sometimes this loan is given in cash and sometimes as credit against payments for land and water. At first, the state gave no aid in equipping farms. Now, it provides some costly implements which are loaned to settlers for a small charge. It keeps pure bred bulls in the dairy districts for the use of settlers and where the settler is known to be competent and reliable, it furnishes both horses and cows, the settler paying a deposit or giving additional security.

The extension of this aid would be hazardous if it was not accompanied by the oversight of settlers by capable, practical men. A scheme having so many generous features is certain to attract a considerable number who are indolent or impractical, and who seem to believe that the world owes them a living—or, in the language of Victoria, that it is the business of the state to spoon-feed them. Such settlers have to be promptly eliminated, and the Victorian Act provides for this.

There are other settlers whose lack of experience would result in costly mistakes if left to work out their own salvation. To guide and encourage the industrious beginner and weed out the failures, the state locates in each settlement an officer known as an inspector, who makes frequent visits to each farm, observes the progress made in improvements and cultivation and reports thereon to the commission in charge of the work. It is these reports which determine quite largely the extent of the financial aid which will be given a settler. If two-thirds of the farm is not brought under cultivation by the end of the second year further financial aid will be refused unless exceptional conditions cause the delay. At first, settlers are inclined to object to this oversight, as they regard it as interference with their private affairs, but it does not take them long to realize the value of being able to obtain competent advice free.

A good inspector soon brings his settlers to act together for their own good and for the reputation of the district. The emulation between settlements works wonders in hastening the cultivation of all the land.

The state retains the ownership and management of canals. During the first year, settlers are only required to pay for the water they use. After that they pay for the water allotted to their land, which rarely exceeds the water used. The price of the water is fixed so as to provide 4% interest on the cost of the works besides expenses of operation and maintenance. It is believed that this plan could be adopted with advantage in America on the Reclamation Service projects. If the ownership and management were retained by the government for 25 years and settlers required to pay only operating expenses and 4% interest on the cost, it would greatly reduce the earlier payments, and relieve settlers from the responsibility of management until they had gained experience.

In Victoria, settlers are given 31½ years in which to pay for their land, with interest at 4½%. The farms vary in size from two-acre blocks intended for farm laborers, up to holdings having a value of $12.500. The average-sized fruit farm at present is about 30 acres, and the dairy farm from 40 to 50 acres, experience having shown that these areas are all that the farmer and his family can properly cultivate unless considerable hired labor is used.

In equipping and improving these farms the state invests much more money than the settler, and it has to do this if the chance for a living is to be open to men of less than $1000 capital. The intention is to provide homes for farm laborers without capital and to enable farmers with a capital of $1000 to secure farms of 40 acres or less.

The following table will show the amount of money invested by the settler and by the state in a dairy farm of 40 acres, costing $60 an acre.

		Paid by settler	Paid by state	Period of deferred payments	Interest rate
Land	$2400	$144	$2256	31½ yr.	4½%
House	1200	150	1050	20 yr.	5%
Grading and seeding 15 acres	325	65	260	10 yr.	5%
2 horses	250	50	200	5 yr.	5%
20 cows	800	160	640	3 yr.	5%
	$4975	$569	$4406		

This does not take into account the expenditure for milking shed, outbuildings and fencing, but 60% of the latter outlay can be returned to the settler as a loan as soon as the improvements are completed, and this will pay for the material needed. One great merit of this plan

is the way it protects the settler from using up his capital for living expenses. One with $2000 who has to build his own house and grade and seed his land consumes about half his capital in living before he gets any return from cultivation, but with the house built and the alfalfa or other fodder crop sown before hand, the capital all goes into development.

In addition to the outlays mentioned, the settler must buy furniture for his house and harness for his team. He must have a wagon or cart, a cream separator and cans, a plow, a harrow, a mower and rake. He cannot buy these things and pay his deposits unless he has a cash capital of $1000 but the number who have $1000 is many times the number who have $5000 and under this scheme the capital needed is reduced with the acres taken.

Providing ready-made farms for settlers has brought about a larger extension in the irrigated area in the last four years than was obtained in the 25 previous years in which settlers were left to work out their own salvation, unaided. It has so increased the revenue from canals and the payments by settlers have been so satisfactory that the state is now considering a large extension of the irrigated areas and opening up for settlement areas of less than 20 acres, on still more liberal terms of payment.

The opportunities for extending such aid in America are greater than in Australia. Money can be obtained here at a lower rate of interest. In America there is a greater number of home seekers and settlers and they do not have to be brought half way around the world, as is the case in Australia. We also have more skilled irrigators, whose services could be obtained for purposes of instruction. The need is so great and the chances of success so encouraging that it is hoped state aid in creating ready-made farms will be tried on at least on project.

The Early History of Bituminous Street Pavements

Although the best known textbooks on pavements invariably state that asphalt or bitumen has been known and used for many ages—that bituminous cement was used for the walls of ancient Babylon—these same books are invariably hazy on the first use of asphalt during modern times for street paving.

The brief article in our issue of Apr. 30, 1914, p. 945, describing an experimental pavement on Oxford St., London, England, in 1839, gives a bit of the earliest history of bituminous pavements in England. Since that article was published we have found among the "Papers on Practical Engineering published by the Engineer Department for Use of Officers of the Corps of Engineers" an excellent monograph on "Bitumen," written by Lieut. H. Wager Halleck in 1841, and in view of the recent history of bituminous pavement and the patent fights over methods of construction we deem the following facts compiled by Lieut. Halleck worthy of the attention of present-day pavement experts.

Regarding the early use of native bitumen he writes:

For 25 to 30 years (written in 1841) mineral tar, in combination with sand and calcareous matter, has been used in Bordeaux and its vicinity for roads, pavements, floors and the roofing of houses. It was first used, with stone only, in the repair of roads near Bayonne, and being found to answer the purpose, it came afterward to be employed by builders in its combined form, [illegible] and many houses in Bordeaux are now roofed with it.

Regarding the use of bitumen on macadam roads, Lieut. Halleck described the now so called penetration method as follows:

The soil is first removed to a depth of about 5 in., according to the thickness to be given to the road covering, and the earth well rammed. to make it still more firm, small broken stones, about 1 cu.in. in size, may be driven in. A layer, about 4 in. thick of broken stone from ¾ to 1 in. in diameter is spread over and smoothed off so as to give the surface a slight curvature. Over this is poured a very hot and liquid mixture, of one-third coal tar, one-third pulverized asphaltic stone (of an inferior quality) and one-third fine sand. A sufficient quantity should be put on to penetrate all the crevasses of the stone and form a solid mass. After this has become cold, a layer of good bituminous mastic about 1 in. thick, is applied, and, while still hot, is covered with a layer of broken stones about 1½ in. in diameter, placed close together, but without touching, and pressed into the mastic by an iron roller. The thickness of this covering may be varied, according to the wear and tear it will have to resist.

The first bituminous pavement laid down in Paris, it seems, was a genuine asphaltic block pavement, in many respects very similar to those now in use. On this subject, Lieut. Halleck quotes M. Partiot, Chief Engineer of Roads and Bridges of France in the "Annales des Pontes et Chaussées," for March and April, 1838:

The first bituminous pavement in Paris was at the entrance of the Place de La Concorde. The pieces of stone (that is, artificial stone or compressed asphalt blocks) are

PLACE DE LA CONCORDE; SITE OF THE FIRST ASPHALT PAVEMENT IN PARIS

(From a photograph taken in the summer of 1913 by H. W. Durham, Chief Engineer of the Bureau of Highways, Borough of Manhattan, New York City. Now paved with wood block on a concrete foundation.)

there arranged like mosaic work, with their smoothest side uppermost, and then connected together by a very adhesive bituminous mastic. They form a continuous and solid mass.

This experiment has not been completely successful, for the road which has been in use since [illegible] 3, 1837, is already (March, 1838) worn away in many places, but this is the result of defects in the execution of the work. The contractor erroneously considered that his bituminous mastic was capable of resisting the direct action of the wheels and horses' feet. This mastic, which attaches itself very strongly to the stones, should be used only for cementing them together, so as to form one solid block, but it should not be visible, the stone alone being seen upon the surface. The stones of this pavement were not placed near enough together, and the interstices were filled with bituminous mastic, which is not capable of resisting friction, so that the joints are open, and the surface of the road, although at first smooth, has already become rough and uneven.

These defects might have been avoided if the following precautions had been taken. The fragments of quartz should have been placed as close together as possible, and the intervals between filled with small chippings of stone, which the larger masses would have sufficiently protected; these artificial paving stones should have been placed diagonally, in order that the direction of the joints should not have been lengthwise of the road. Moreover the width of the joints

should have been only 0.3 to 0.4 in. instead of 1½ to 1¾ in., as they really are. . . .

So far as ease of traveling or cheapness of draft are concerned, the bituminous pavement will always, without doubt, be preferable to the ordinary paved or broken stone roads. [These pavements cost about $2.53 per sq.yd.]

Lieut. Halleck describes further on in his monograph the construction and use of asphalt blocks, as follows:

Pavements have been made in Paris of fragments of quartz cemented together with bituminous mastic, and shaped by running them into molds. These blocks, properly prepared beforehand, are laid upon a bed of sand, and the joints, which are about 0.4 in. wide, filled with mastic [patented binder].

It appears from the foregoing that asphaltic pavements were laid in Paris in 1837; and from that time forward there was a gradual development, the heavy rolled compressed sheet asphalt, like pavement in use there today, which is, in most instances, a natural rock asphalt, was developed about 20 years later. But is also appears that asphalt had been used on roads in Bordeaux at least a quarter of a century before being tried in Paris. This is probably the earliest use during modern times of asphalt for road purposes. It is known to have been used in ancient times for mosanic pavements in buildings, halls and court yards, but so far as known it was never used on ancient roads subjected to wheeled-vehicle traffic.

Col. J. W. Howard, Consulting Engineer, New York City, in a lecture before the graduate students in highway engineering at Columbia University, on Jan. 24, 1914, gives the following information on the early use of asphalt:

In 1712, D'Eyrinys discovered, and in 1721 published, a description of the rock asphalt at Val-de-Travers, Neufchatel County, Switzerland, and several uses for this material. D'Eyrinys, in 1735, opened the bituminous limestone deposits at Lobsann (Germany), which deposit has been worked ever since. About 1797, the deposit at Seyssel, France, was opened, and then, like the others, was used for making asphalt mastic by extracting the bitumen from some of the rock and enriching the powdered fresh rock with it.

In 1802, Count de Sassenay took charge and reformed the methods, very much improving them, getting his supplies from the Swiss and French deposits mentioned. Rock asphalt-mastic was soon used for floors, sidewalks, public squares, bridges, and then streets. It was in Lyons, France, about 1834, that in mastic form, it succeeded fairly well for street paving. In the same year it entered Paris and rapidly became almost universally used for sidewalks.

Meriam began about that time to observe that lumps of the broken and powdered bituminous limestone, dropping from wagons near the quarries, were crushed and coalesced under wheel traffic into a firm, continuous sheet on the roads. It was then that the noted engineer, Leon Malo, of France, entered the industry and devoted his life to it. He is known throughout the world as the father of the asphalt industry.

Delano, of England, colabored with Malo in France, and introduced sheet-asphalt pavements, made of European rock asphalt, and asphaltic-mastic sidewalks, floors, etc., into England and the cities of almost all nations.

In 1854 Malo, after some experiments, laid the first successful sheet-asphalt pavement. It was made with compressed natural rock asphalt. He demonstrated the necessity of a firm concrete foundation. The wearing-surface layer was made by crushing, powdering, and then heating the bituminous limestone and spreading and compressing it in place on the street. This first street was Rue Bergere, Paris, which, from the first, was successful, and by proper maintenance it has been kept thus paved in constant good order for 60 years to date.

The success of compressed, rock-asphalt pavement in Paris since 1854, has attracted the attention of all important cities. London, England, began its use by paving Threadneedle St., in 1869, and has steadily extended its use to many other streets of that city. Geneva and Berlin began in 1871, and all the principal cities of Europe soon followed.

Its extensive use in America was prevented, first, because of the heavy freight charges from Europe, and secondly, because of the invention by DeSmedt of the American form of sheet-asphalt pavement. He laid his first piece on William St., Newark, N. J., in 1871, then in other cities, and in 1876 on a portion of Pennsylvania Ave., Washington, D. C., where his artificial composition of sand, limestone powder, and asphalt cement proved successful.*

Suggestions as to the Maintenance of Driven Wells, at Lowell, Mass.

Although in some parts of the country, driven wells are commonly used for public water-supplies, they are usually confined to relatively small cities. One of the larger cities with a driven-well supply is Lowell, Mass. In reporting on the possible treatment of the Lowell water for the removal of iron and manganese, F. A. Barbour, Consulting Engineer, Boston, Mass., made some suggestions regarding the maintenance and operation of the Lowell wells that may be of service to those in charge of driven wells elsewhere.

After speaking of the desirability of distributing the draft of water uniformly over the whole field, Mr. Barbour says:

To do this, it will be necessary to keep the well strainers in better condition than in the past—first, by washing down all wells, instead of driving, and second, by using an all brass well strainer section, instead of the iron and brass section now employed, in which the electrolytic action between the two metals contributes to the clogging of the strainer.

The present Boulevard system comprises some 450 wells, connected to a number of suction lines, which converge with the main pipe leading to the air chamber at the station. The several lines of wells vary considerably in age, and in the condition of the strainers, and thus it is that, under the vacuum maintained at the station, the new wells, or those last cleaned, have furnished the greater part of the water, and the quantity drawn from these new wells has been so large that the clogging of the strainers by silt is accelerated, and the quality of the supply rapidly depreciated by overworking the adjacent ground. The obvious remedy is to maintain the well strainers in reasonably uniform condition, and by partial closing of the gates to different degrees on the several suction lines, to so balance the water drawn from different parts of the well field that the water table will be more uniformly depressed—a larger area of subsurface sand being thus made effective in the filtration of river water, and the average rate of filtration by this increase in effective area being inversely reduced.

As already stated, in the past the greater part of the water has been drawn at high rates from a rather limited area, which shifts in location as the wells are cleaned, or new wells are driven. It is now proposed that when new wells are driven, the draft from these wells shall be limited to the quantity which they can reasonably continue to supply without too rapid clogging of the strainers or overworking of the adjacent soils; that the quantity drawn from each section of the field shall be determined by pitometer gagings, and that these gagings, together with observations of the elevation of the water table in test wells, shall be made the basis of a system of control such that the total area of the well field will be more uniformly worked.

It is necessary to recognize that the continued maintenance of a driven-well system requires thorough development of the wells when driven, the use of material in the well points which will not corrode, and a control of the draft from the different sections of the field which will, as far as possible, not overwork the soil in any one section to the detriment of the quality of the water. By the methods proposed, and which can be carried out under the supervision of the operator in charge of the purification plant, it is believed that a greater quantity of better water than has been obtained in the past can be drawn from the territory in which wells are already driven, and that the continuous increase in the amount of iron and manganese, which has been in evidence in the past, will be checked.

Reconstruction of a Jersey City Railway Passenger Terminal

SYNOPSIS—Reconstruction of a railway and ferry terminal handling about 50,000 passengers per day. Existing buildings and ferry slips were either replaced or remodeled and the whole terminal enlarged. High trainshed was replaced by a large shed of the low type. The site is made ground of depth up to 110 ft.

※

The complete reconstruction of the Jersey City passenger terminal of the Central Railroad of New Jersey, in progress since 1911, is being rapidly brought to conclusion. In addition to the passenger service of the New Jersey Central, the New York passenger traffic of the Philadelphia & Reading Ry., the Baltimore & Ohio R.R., and the Lehigh Valley R.R. is handled through this terminal. The Lehigh Valley was taken on in 1913, during the heaviest construction. About 50,000 passengers are handled per day and most of the business is short-haul commutation business.

While the work was in progress about 185 trains per day were handled in each direction, on the two main-line tracks and the two tracks of the Newark branch—four passenger tracks in all. The passenger-coach yards, the locomotive terminal, the U. S. Express Co. offices, the Pullman yard and service buildings were on the north side of the main line.

The work comprised the following elements, proceeding east from the river bank: Erection of a new two-story double-deck ferry house with [illegible] rearrangement of the old station buildings; building a three-story steel, brick and concrete building, [illegible], for handling express business, offices, records, etc.; the erection of a service building for power purposes, e.g., heating, cleaning service, water and compressed air; rebuilding two small piers in the North River; demolition of the old style steel trainshed and erection of a low shed covering a much larger area. Fig. 1 shows the extent and scheme of this work. The table gives dates and rate of progress on the several elements.

A general idea of the size of the work may be had from the following figures: the ground area occupied by the station and ferryhouse is 2.31 acres; by the train concourse, 0.52 acre; by the new trainshed, 7.18 acres.

Double-Deck Ferryhouse and Slips

An old one-story wood structure was torn down in May, 1912; and in June, 1914, a new and modern steel-frame two-story building with reinforced-concrete floors, terra-cotta block partitions, a concrete roof covered with tar and slag, and an ornamental copper front, was erected. In addition to the ferryhouse, four slips with pile racks were constructed. With this work commenced the active construction on the passenger-handling section of the enterprise, through all of which traffic was not interrupted. To maintain normal service two temporary slips, one on each side of the existing four, were built and the two northern slips abandoned, leaving four still in operation. The buildings between these two northern slips were then torn down, part of the ferry concourse was closed, and the foundation work on the northern half commenced.

When the northern new slip had been rebuilt and placed in service, old No. 3 slip was taken out of service, and when the ferry bridge of new No. 4 was put in service old No. 3 slip was demolished, as was also the southern half of the old ferryhouse. The foundations for the southern half were placed in a manner similar to that employed on the northern half. All the foundation work was completed in December, 1913.

The ferry bridges are of the wooden bowstring truss

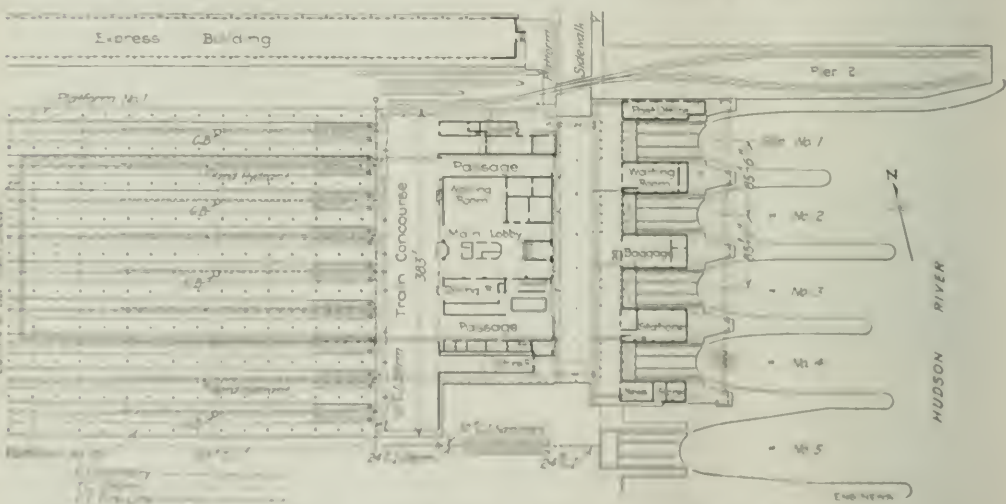

Fig. 1. General Layout of Ferry House, New Station and Trainshed

FIGS. 2-3. OLD AND NEW FERRY HOUSES AND SLIPS

OLD CONSTRUCTION NEW CONSTRUCTION

type, 79 ft. long, with one end supported on a rocker beam. The off-shore end is raised and lowered by electric-driven machinery, supported on steelwork entirely separate from the building. The raising and lowering of the bridges to fit varying conditions of tide and boat-loading is accomplished at a speed of about 6 ft. per minute.

The ferryhouse is fireproof throughout and rests on about 5000 piles 60 to 80 ft. in length with a butt diameter of about 14 in., driven through soft mud to rock. The building contains 1500 tons of structural steel, 7000 cu.yd. of concrete, and 1,800,000 ft. b.m. of lumber in the foundation under water and in the ferry racks.

The contractor's plant for the foundation work consisted of two floating piledrivers and two floating derricks. The land piles (west of the bulkhead) were driven by a standard land piledriver equipped with a 1½-ton drop hammer.

Gravel, sand, etc., for the substructure were delivered on scows from which they were lifted by a floating derrick to a large concrete mixer. This mixer was situated on a fixed platform supported by piling, about 20 ft. east of the bulkhead. From the mixer it was lifted in a steel tower about 60 ft. high to chutes suspended by wire cables. These chutes were shifted as desired, during the work. Materials for the superstructure were delivered by cars to a mixer located on land, from which the concrete was conveyed by wheelbarrows to a hoist and lifted to the upper floor and roof.

During the latter part of 1912 and the first part of 1913 when the foundations were under way, the work was pushed hard; as many as 400 men per day were at work, representing weekly payroll of approximately $9000. This work was prosecuted in two shifts of 8 hr. each.

The steelwork was furnished by the American Bridge Co. G. B. Spearin, of New York City, placed the substructure and erected the steel for the new ferryhouse. The superstructure was erected by C. T. Wills, Inc., of New York.

REARRANGING OLD STATION BUILDING

The old station was a three-story brick building on pile foundations. It was constructed about 1888, and not

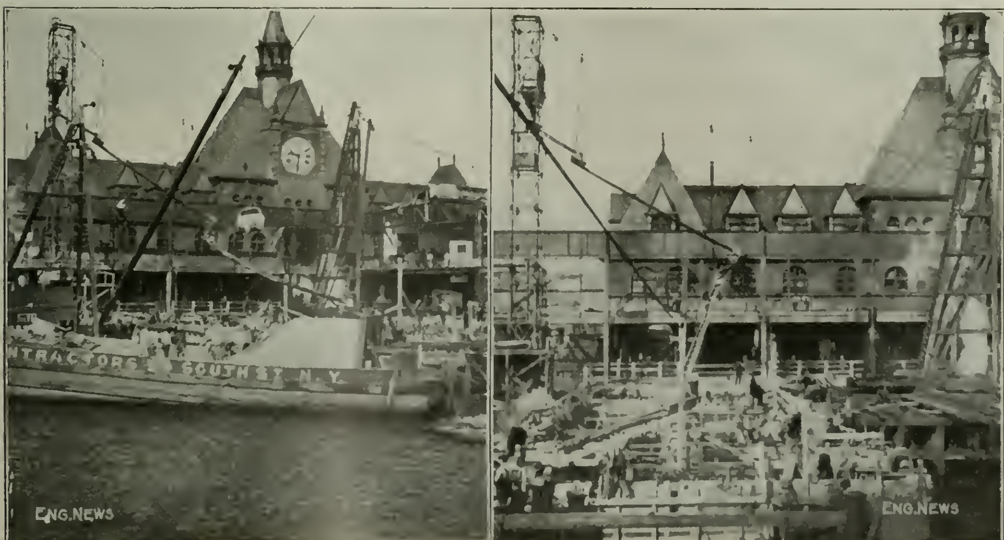

FIG. 4. CONTRACTOR'S PLANT ON FERRY HOUSE CONSTRUCTION

will suffice for present needs. It was found, however, that the same outside walls could be used, only a rearrangement of the first floor interior was necessary. Part of this floor was formerly used for conductors' and brake-

Fig. 5. A Completed Slip and a Portion of New Ferry House

mens' layover rooms, stores and records, ticket offices, baggage, mail rooms and other various uses. This floor was completely remodeled and given over entirely to passenger business. The upper two floors were left practically unchanged.

A small interior structure, 16x20x10 ft. high, was constructed in the center of the old waiting room to be used for ticket offices, information bureau, telegraph office and parcel room. The first floor of the station building is divided into three general bays, the central portion (formerly the waiting room) is now called the main lobby. The entire south wing is given over to restaurant, café and grill room. A tiled floor, tile wainscoting and plaster side walls and ceiling replace the old wood floor, wainscoting and ceiling. The rearranged north wing is given over entirely to waiting rooms, smoking room and toilets. The main waiting-room has a terrazzo floor laid on concrete arches, with green-tile wainscoting and plaster walls and ceiling. It is lighted by a large leaded-glass skylight in the roof as well as by large windows opening on the train concourse and main lobby.

A feature of the station improvement is the wide central stairway in front of the ticket offices leading from the main lobby to the upper deck of the ferry concourse. The main lobby was given a new red-tile floor laid on the steel and concrete base of the old floor; and the whole inside of the station was cleaned, repainted and refitted.

Another important feature is the addition of two inclines, one on each side of the station building, leading from the train concourse to the upper-deck ferry concourse. They slope 1 in 10, and have cement floors with carborundum finish to prevent slipping. They were thrown open to passenger traffic April last.

North of the old depot was constructed a new two-story building containing the station master's office, the trainmen's layover room and a substation for light and power.

Service Building

The service building contains the heating plant, consisting of six 250-hp. boilers for station and yard heating; a fire pump of 90,000 gal.-per-hr. capacity; vacuum cleaning machines for cleaning the station and the cars in the yard; and a 2500-cu ft.-per-minute air compressor for train charging for airbrakes and for train-signal operation in the terminal.

Construction of Two Piers

The work of rebuilding two railway piers just north of the ferry slip has not yet been commenced. Pier No. 2 is intended for the railway-mail service, which has greatly increased during the past two years on account of the addition of the parcel post. Here also will be delivered westbound mail from incoming steamships, thus saving several hours on this class of matter. Pier No. 1 is used for the emigrant service, and will continue to handle this travel after remodeling.

Low Trainshed

The outline of the old trainshed is superimposed on Fig. 1, which shows the new layout. The old structure was 512x216 ft. in plan, with a three-truss roof 142 ft. 7 in. in span, trusses spaced 32 ft., 70 ft. high from top of rail to peak. There was also a small lean-to 36 ft. 6 in. wide on each side. Within this shed were 12 tracks of 90 cars capacity. The old shed was built in 1888 and re-

Fig. 6. New Trainshed and Station, from the West

(The [illegible] building on the left is the [illegible] building. The sky-line of New York City is in the distance.)

quired for its maintenance a permanent gang of painters on account of the corrosion due to locomotive gases.

In July, 1912, the work of replacing this old shed with a shed of the Bush type was started. The new structure covers an area of 817x383 ft. and has 20 platform tracks with a capacity for 225 cars. The roof is supported on round cast-iron columns spaced 27 ft. c. to c. along the platforms. There is an 11-ft. cantilevered roof on each side. The distances from top of rail to top of platform and from top of rail to underside of smoke duct are 6 in. and 16 ft. 3 in., respectively.

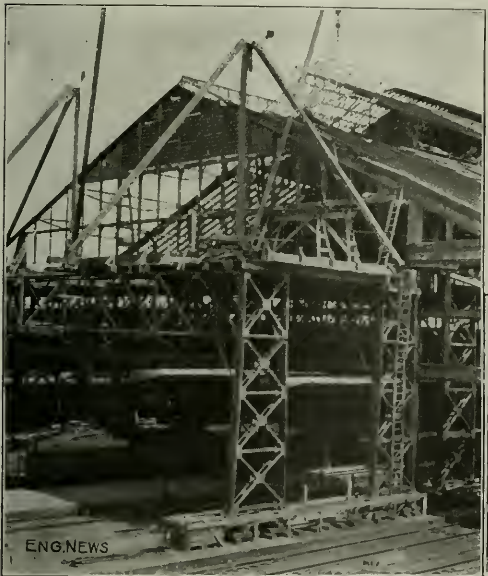
Drainage is furnished by wrought-iron pipe leaders carried inside the supporting columns. These leaders run to a terra-cotta drainage system, situated between alternate pairs of tracks. This system discharges into a 3-ft. trunk sewer, south of the station and is carried thence to the North River.

The reinforced-concrete platforms and concourse are carried on reinforced-concrete girders, supported on concrete piers which rest on wood piles below groundwater level. About 4000 piles were used in the foundations of the shed and concourse. These piles are from 50 to 110 ft. long, the longer ones being spliced. The splice is made by means of 24-in. steel dowel-pins 1 in. in diameter or by an iron collar 12 in. in diameter and 24 in. long, of ½-in. metal, for reinforcing the joints between pile and follower. The tracks themselves are carried on the natural surface, which is all filled ground, the fill having been made some years ago when the old trainshed was built.

During the progress of the work the pier excavations were kept dry by means of hand pumps and portable gasoline-driven pumps. Most of the excavation was done by hand, but later in the job a locomotive crane with an orange-peel bucket was used.

Piledriving was commenced on the south side of the old trainshed in July, 1912; and shortly afterward on the north side. Early in 1913 platforms 10, 9, 8, 1 and part of 2 with shed roofs 1, 8 and 9 were completed. The new tracks covered by these roofs were completed and connected with the interlocking system in March, 1913. These tracks were located just north and south of the old trainshed, traffic inside the shed therefore not being interrupted as yet.

On Apr. 8, 1913, the removal of the old shed was commenced, the large central portion being taken down first,



Figs. 7 and 8. Traveler Starting Removal of Old Trainshed

(The traveler was built of three standard 8-track steel signal bridges, mounted on a timber frame on wheels, and covered with a continuous platform. The first bridge carried the blocking; on the second were two derricks; the third carried the boilers and hoisting engines for operating the derricks.)

Between tracks in the shed are steel intertrack fences, and the platforms are blocked off at the train concourse by a sliding-panel fence. At the rear of each track and facing the station are Hutchinson train indicators, which display on large banners the departing time and station stops of the trains.

Between the shed and the station is a concourse, 58 ft. 6 in. wide, running the whole width of the train shed. This is a striking feature of the whole construction. It is separate from the station building and is constructed of heavy steel-arched girders resting on steel columns, supported by piles. Along the center of the roof runs a self-ventilating skylight 19 ft. 6 in. wide. The face of the structure above the trainshed roof is fitted with side lights in movable steel sash. The ends of the concourse are inclosed in glass; the lighting and ventilating arrangements are very liberal.

then the southern leanto. Meanwhile work was started on platform 7.

The work was pushed from south to north. New platforms were put in service as old platforms were discontinued. The work was carried on in pairs, i.e., when a new shed covering two tracks had been finished, the tracks were put in service and two old ones were taken out. When the work was started, 14 tracks were in service. It is worthy of note that thereafter, 16 tracks were always in service and on Saturdays and holidays, from 17 to 19 tracks could be used.

Getting material to and from the site without delaying the 370 trains per day and the many drill movements between the locomotive terminal and the trainshed, was no small problem. Work was carried in two shifts of 8 hr. each; the number of men at work reaching 450, involving a payroll of about $10,000 per week.

The plant used on this work consisted of two standard piledrivers, one with a 1½-ton drop hammer, the other with a 3-ton steam hammer. The rate of driving averaged about 10 piles for each piledriver per 8-hr. shift; being largely affected by the large area and the small concentration of work in progress within this area, due to its dependence upon traffic conditions.

Concrete was mixed by two mixers located on flat-cars. For the piers, girders and platforms, the concrete was chuted in place. The concrete for the roof was delivered from the mixer through a short chute to the bucket of a wooden hoisting tower situated on an adjacent flat-car. From this tower, concrete was distributed by means of three chutes fastened together and supported by two derrick booms projecting from the tower. This rigging was very flexible and could be quickly moved from point to point.

The steelwork and cast-iron columns for the shed framing were delivered to the job on cars and lifted directly into place by a small locomotive crane, having a 36-ft. boom. The steel for the large concourse was placed by a larger crane having a 70-ft. boom. The latter work required great care on account of the surrounding passenger traffic. This crane handled steel members weighing as high as 13 tons, from very awkward positions.

The construction of the trainshed, train concourse and platforms involved the driving of 4000 piles, the placing of 23,000 cu.yd. of reinforced concrete; 30,000 cu.yd. of excavation; 6000 lin.ft. of terra-cotta drain, and about 2700 tons of structural steel.

The general contractor was R. P. & J. H. Staats, of New York.

Method of Removing Old Trainshed

The 14 steel-roof arches of the old trainshed carried a slate roof laid on wood purlins and roofboards, and a large central skylight and ventilator. In taking down the steel, the skylight, ventilator, slate and roofboards were removed first and lowered by hand to cars on either side. To take down the heavier members, a traveler was erected, consisting of three 8-track, steel signal bridges with steel bents supported on a timber frame mounted on six wheels, three per side, running on one rail on each side, laid on two of the old concrete platforms. Opposite wheels were 108 ft. apart, and the clearance between the shed roof and the top of the traveler was 24 ft.

The traveler was erected just west of the old station on a Sunday morning without interference to traffic. Two locomotive cranes placed the leg frames while the signal bridges were being lifted one at a time from flat-cars by a wrecking crane and swung at right angles across the tracks. The two locomotive cranes hooked on to a signal bridge, one at each end, and lifted it to position, where it was bolted to its legs. After the three bridges were placed they were joined together and a light, timber platform laid over them.

Fig. 9. General View of New Trainshed Construction, Looking West

([illegible] completed sheds with tracks in operation; roof 4 under construction, showing [illegible] tower on flat car, and the [illegible] mixer under roof 5 for concrete platform slabs; pile drivers working on platform at right of picture; trenching for drainage mains between tracks; temporary wooden butterflies over tracks in operation, at extreme right.)

FIG. 10. INTERIOR OF NEW TRAINSHED

FIG. 11. INTERIOR OF TRAIN CONCOURSE

The first section of the platform carried the blocking; on the second section were two derricks for lowering the steel; while on the third were the boilers and hoisting engines for operating the derricks.

In operation, the traveler moved eastward. The forward bridge was run under a truss to be removed; the wood roof beams, steel purlins and the steelwork of the monitor were lowered to cars underneath. The truss was then blocked up and cut into section by the oxyhydrogen flame. About 870 tons of old steel were removed. After removing the main shed, the steelwork of the north leanto and later the south leanto was removed by a locomotive crane.

The traveler was erected Sunday, Apr. 13, 1913, started removing material Apr. 20, and was dismantled on Sunday, May 21. This work was accomplished without delay or accident. Trains were run under the traveler which spanned six tracks, and on both sides of the traveler. Two tracks were used for loading the steel removed. Canvasses were hung to protect passengers from falling rivet heads, small pieces of steel and dirt; and as the work

*Six bays or twelve-track width of the shed not to be entirely completed until new interlocking tower is in service, probably early in 1915.

progressed, wood butterfly sheds were erected on three platforms to protect passengers from the weather.

Greater difficulty was experienced in dismantling the traveler than in its erection, on account of the wood butterfly sheds put up in the meantime. The same general method and plant, however, were employed. The bridges were unbolted, one at a time. Locomotive cranes then hooked on to each end and moved westward under their own power, carrying a bridge with them above the butterflies. At a point west of the butterflies the bridge was lowered to the ground. An erecting crane then swung it around and onto a car. Meanwhile, the locomotive cranes had returned for another bridge.

The operations of assembling and dismantling the traveler required but about four hours each. This removal work was done by Terry & Tench, of New York.

CENTRAL RAILROAD COMPANY ORGANIZATION

Reconstruction work was accomplished under the supervision of the Engineering Department of the Central Railroad of New Jersey: J. O. Osgood, Chief Engineer; A. E. Owen, Principal Assi tant Engineer; J. J. Yates, Bridge Engineer; A. M. Zabriskie and H. E. Van Ness, Assistant Engineers of Design; and C. M. Titworth, Assistant Engineer in Charge of Construction.

Government Forest Reservations in the Eastern Appalachians now amount to 1,104,000 acres, for which $5,556,000 have been paid. Of the land purchased up to date, about 133,000 acres is in the White Mountain area in New Hampshire and the balance is in various parts of of the Southern Appalachians, from Virginia to Georgia. About $2,000,000 of the original appropriation remains available for additional purchases during 1915.

The Effective Width of Reinforced-Concrete Slabs Supporting Concentrated Loads

By C. R. Young*

The frequency with which reinforced-concrete slabs are subjected to concentrated loading is sufficient to warrant careful determination of the lateral distribution of the loads. Practically all loads on highway-bridge floors are of this class, and although the floors of buildings are usually designed for uniform loads, the actual loads are applied over a relatively small area of the floor surface.

Nevertheless, uncertainty and considerable divergence of opinion still exists among engineers concerning the proper methods of proportioning slabs thus loaded. The method adopted is usually based on a more or less rational guess at the probable lateral distribution of the load and then an inch or so is added to the calculated thickness "to be on the safe side and to allow for wear." Building codes and general specifications for the structural work of buildings are practically silent on the matter and few highway-bridge specifications make any mention of it. The engineer is thus left largely to his own judgment in making loading assumptions that not only greatly affect the proportions of the slabs themselves but have an important effect on the weight and cost of the structure as a whole.

The only safe bases upon which to found any rules indicating the lateral distribution of concentrated loads must be experimental. For this reason, the results of such tests as appear to have any bearing on the matter will be briefly reviewed, and from them general distribution rules will be established, giving the effective width in accordance with the experimental evidence available at the present time.

In June, 1913, A. T. Goldbeck, Testing Engineer of the United States Office of Public Roads, presented a paper to the American Society for Testing Materials setting forth the results of a series of tests of reinforced-concrete slabs subjected to concentrated loading. These slabs varied from 4 to 7 in. in total thickness and, with the exception of one 6 ft. wide and 14 ft. long, were all 7 ft. wide by 9 ft. long. Loads were applied centrally over a bearing area 6 in. in diameter in case of the latter slabs and by means of one-half of a vitrified paving block for the 6x14-ft. slab. Careful observations made up to the point of failure indicated that at a distance of as much as 1½ ft. on each side of the central load, the slab carried considerable resisting moment, even in cases where no transverse reinforcement was provided. While hesitating to draw conclusions from what seemed to him insufficient data for generalization, Mr. Goldbeck stated that "in slabs of the kind tested and from 5 to 6 ft. in span the concentrated central load might be safely considered as carried by a width of slab equal to not more than 0.8 of the span length and the moment might be regarded as uniformly distributed over this 'effective width.'"

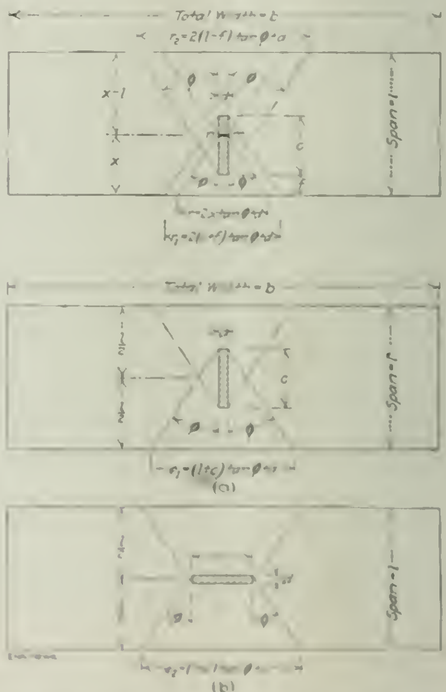
W. A. Slater, Test Assistant of the Engineering Experiment Station of the University of Illinois, in discussing Mr. Goldbeck's paper, cited a related series of tests being carried on at the University of Illinois. The tests then completed were made on (a), a large number of beams having a span of 4 ft. and widths varying from one-half the span up to twice the span; (b), one beam having a span of 10 ft. and a width half as great, and (c), two beams having a span of 30 in. and a width of 3.2 times as great. The loads were applied at the one-third points of the span.

On the basis of the latter tests and of those reported by Mr. Goldbeck, Mr. Slater recommended that where the total width is greater than twice the span, the effective width e be assumed as

$$e = \tfrac{4}{3}x + d$$

Where x = the distance from the edge of the concentrated load nearest the support considered to that support;

d = width, at right angles to the span over which the load is applied.



FIGS. 1-3. DIAGRAMS SHOWING POSITION OF CONCENTRATED LOADS ON SLABS

For slabs having widths less than twice the span, reductions in the effective width are recommended by Mr. Slater in accordance with a curve plotted from the results of the tests made at the University of Illinois. It was pointed out that, so far as tests had indicated, the effective width was but little influenced by the depth of the slab or by the percentage of longitudinal reinforcement. The introduction of transverse reinforcement would, no doubt, increase the effective width but this matter had not been investigated.

A striking conclusion arising from these results is that [illegible] the effective width for point loading is a constant

*Assistant Professor of Structural Engineering in the University of Toronto, Toronto, Can.

proportion of the span, the depth of slab required to support a concentrated load would be approximately the same for all spans.

Confirmation of these conclusions with respect to the width of slab over which a concentrated load is distributed is afforded by analysis of another series of tests undertaken for quite a different purpose. In his "Discussion of the Basis of Design for Reinforced-Concrete Floor Slabs," in the *Proceedings* of the National Association of Cement users for 1911, A. R. Lord draws attention to a number of tests made at the University of Illinois in order to throw light on the lateral distribution of stress in wide beams. This is an important consideration in the design of girderless floors, since it is desirable to know whether only those rods of a belt which pass over the column capital may be taken into account in figuring the resistance to negative bending moments, or whether some or all of the remaining rods of the belt may be included. The beams tested were 3 ft. wide, 4 ft. 10 in. long and 3 in. deep to the reinforcement. They were loaded across their full width at the ends and were supported at the third points, in some cases for their full width, in others for one-half of their width, and in still others for one-fifth of their width. The beams supported for half their width carried, taking the average result, the same load as those supported for their full width. Those supported for one-fifth of their width, and without transverse reinforcement, carried 14.4% less load than those supported for their full width, but for two other beams supported in the same way and provided with 0.4% of transverse reinforcement, the falling off in the load carried was only 3%.

If, now, the wide beams thus tested be considered *upside down*, they would become simple beams of approximately 4 ft. 8 in. in span loaded at the third points with loads bearing, in some cases, on only one-fifth of the width of the beam, in other words, with concentrated loads. From the loads actually carried, it is evident that the moment arising from such concentrations was distributed fairly well over the width of 36 in., even in the case of those beams without transverse reinforcement, and with surprising uniformity for those transversely reinforced. It follows that what has been called above the "effective width of the slab" would, on the basis of the tests just cited, be about 31 in., or 0.55 of the span of the slab. According to the rules given by Mr. Slater, the effective width would be about 25.5 in. or 0.46 of the span of the slab.

Further light is thrown on the subject of the lateral stiffness of slabs by a study of the Tests of Reinforced Concrete Footings conducted by Prof. Arthur N. Talbot at the University of Illinois Engineering Experiment Station and reported in Bulletin No. 67 of that institution. For a series of column footings 5 ft. square supporting a central pier 12 in. square it was observed that "about three-fourths of the steel is effective in resisting the calculated bending moment, or rather the stress in the highest stressed bars is the same as if three-fourths of the steel bars, equally stressed, made up the resisting steel." According to this, the effective width of the footing slab would be 45 in. or 0.75 of a hypothetical span equal in length to the side of the footing. Applying Mr. Slater's rules to this case the effective width would be 40.3 in., or 0.67 of the span.

A series of tests which may be expected to solve many problems connected with this matter was commenced by Prof. C. T. Morris of the Ohio State University in 1911, but no report has been issued further than a statement by Prof. Morris that the results conformed in general with those reported by Mr. Goldbeck.

With the object of affording some guidance to designers in estimating the effective width of slabs supporting concentrated loads, the writer submits below an analysis of the problem and working formulas derived therefrom based upon the experimental results already described.

Let a concentrated load, bearing on an area of length c and width d be applied in any general position to a slab having a total width b not less than twice the span length l, as shown in Fig. 1. If any small element of this load, as mn, distant x from the nearer support, be considered, it is directly evident from the experimental investigations cited above, that such part of it as is delivered to the nearer support may be regarded as wholly transferred to that support within lines drawn through the end points of the element making angles ϕ with the direction of the span of the slab, the tangent of which angle is between 0.67 and 0.80. For brevity, the angle between these two bounding lines, that is 2ϕ, may be called the "effective angle." The reaction at the near support may thus be regarded as uniformly distributed over a width of $r = 2x \tan \phi + d$, or if $\tan \phi$ be assumed as 0.67, a conservative value in the light of experimental results, this width becomes $1.33\, x + d$.

Although there is no direct experimental evidence that the effective angle to the farther support is the same as to the nearer, careful consideration of the matter leads to the conclusion that it is. If the farther support were moved in so that the element of load, mn, became central, the effective angles to the two supports would be equal. There would then be applied to the shifted support along a length that may be called the effective reaction-width of the reduced span a uniformly distributed reaction which, when the first support was replaced in its original position, would become a concentrated load on the original span. The virtual load would be delivered to the support nearest to it, but farthest from the original eccentric element of load mn within the same effective angle as would apply to the nearer support in any case. It thus appears that the effective angles from any element of loading to the two supports are equal.

When the selected element of loading is not at the center of the span and the reactions at the two supports are thus not distributed over the same effective widths, the question arises as to what should be the effective width of the slab for the calculation of resisting moment. It is probable that the average of the two reaction-widths would be the correct width to assume for this purpose, and in the absence of direct experimental evidence on the matter, this assumption is recommended.

Considering as a whole the concentrated load shown in Fig. 1, it follows that the part of it delivered to either support may be regarded as wholly transferred to that support within lines drawn through the remotest corners of the loaded area and making angles with the direction of the span of the slab equal to ϕ, one-half of the effective angle. If f be the distance of that edge of the loaded area nearest a support, from the support, the effective reaction-width, r_1 for the nearest support would be

$$r_1 = 2\,(c + f)\,\tan \phi + d$$

and for the farther support it would be,

$$r_2 = 2(l - p)\tan\phi + d$$

As in the case of an element of loading, the effective width of the slab for the computation of moment of resistance may be taken as the average of the reaction widths r_1 and r_2.

When the concentrated load is a moving one, the critical position will be at the center of the span. The effective reaction widths are then equal to each other and the effective width of the slab for the computation of moment of resistance is equal to either.

Since loads arising from wheels or rollers are often applied over considerably elongated areas, the orientation of the load on the span is an important consideration. For such loads, the distance d is always small—in theory only the width of a line—but the distance c may, for rollers, be as much as 48 in., and is commonly from 12 to 20 in.

The two extreme arrangements of the load, indicated in Fig. 2, will be compared. In Fig. 2 (a), the axis of the machine or vehicle is at right angles to the direction of the span of the slab, while in Fig. 2 (b), it is parallel to this direction. For the usual system of floor construction in a bridge, with the slabs supported on longitudinal stringers, the axis of the machine for the case shown in Fig. 2 (a) would be parallel to the axis of the bridge and for the case indicated in Fig. 2 (b), transverse to it. The latter is a contingency that must be considered in wide bridges. When the load is placed as shown in Fig. 2 (a), it follows from what has already been said that the effective width of the slab e_1 is given by the expression

$$e_1 = (l + c)\tan\phi + d$$

and when the arrangement is that of Fig. 2(b), the effective width is

$$e_2 = (l + d)\tan\phi + c$$

Since c is ordinarily very much greater than d, e_2 is greater than e_1 and the location and orientation of a wheel load most seriously stressing a slab is as shown in Fig. 2(a) and *not* as shown in Fig. 2(b).

For bearing areas differing in shape from those shown in Figs. 1 and 2, equivalent rectangles may be substituted.

When the length b of the slab is less than twice the span length l, it becomes necessary to make some reduction in the effective width. Reference has already been made to the reductions recommended by Mr. Slater. Upon comparing the effective widths indicated by the tests of wide cantilever beams resting on narrow supports, reported by Mr. Lord, with the effective widths estimated by Mr. Slater's rules, it has been shown that the latter give results well on the safe side. The application of these rules to concrete footings also gives results on the side of safety. The writer would therefore suggest that until further experimental evidence is available the values of the e/l to be used in any calculation of effective widths be assumed substantially in accordance with those given by Mr. Slater's graph, or as follows:

$\frac{b}{l}$	
[illegible]	[illegible]

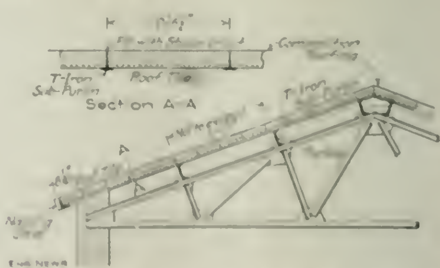
Although no experimental investigation of the relative distributing effects of various types of slab reinforcement has been made, it is probable that a form involving diagonal strands or rods is most efficient. Maximum stiffness along lines radiating from the load within the effective angle and the provision of a large number of strands directly under the load would thus be secured. Upon these considerations the delivery of the load to the supports over a considerable effective width largely depends.

The effect of a gravel cushion or other wearing surface in distributing concentrated loads over bridge floors has not been considered, as this is a matter not entering into the present discussion. Having found the area of the slab to which the load is applied by this surfacing, the problem is of precisely the same kind as arises when loads are applied directly to the slab. The only difference is that the bearing area of the concentrated load is increased with the use of a wearing surface and consequently the effective width of the slab also becomes greater.

Gypsum Slabs for Roof Construction

Rectangular gypsum slabs supported between inverted T-shaped steel sections and covered with a tar felt and gravel offer a light, insulated fireproof roof construction which has been developed by the U. S. Gypsum Co., Chicago, and used in their plant recently finished at Oakfield, N. Y. The accompanying figure shows the details of the construction.

The gypsum slab used in the "pyrobar" tile, made by this company, produced solid, without the cylindrical longitudinal openings, and reinforced, near the surface with a light wire mesh. The tile is 3x12x30 in., and weighs 13 lb. per sq. ft.



Typical Roofing Detail Showing Reinforced Gypsum Tile Laid between T-Section Subpurlins

Steel subpurlins of inverted T-section, $2\frac{1}{2}$x$2\frac{1}{2}$ in., are used, placed 2 ft. $6\frac{1}{2}$ in. c. to c. On the lower flanges of these purlins the tile are laid, starting at the lower section of the roof and fitting the slabs snugly together. The joint between the ends of adjacent tile and over the stem of the T, are filled with a plaster grout, which binds the tile together and makes a smooth upper surface ready for the application of a tar, felt and gravel roof, laid according to standard practice. The composition roof is laid directly on the gypsum tile.

Gypsum tile can be cut and fitted easily, and can be placed in between the steel purlins, using common labor practically altogether. The tile are laid directly on the purlins, and the work requires no scaffolding or false-

work. Forty tile cover one square (100 sq.ft.) of roof. The manufacturers state that such a roof will carry a safe load of 150 lb. per sq.ft., an ultimate load of 600 lb. per sq.ft.

Dump Cars for Transporting Garbage By Rail

At some cities where garbage-disposal plants are located at a distance from the city, the material is transported by rail, and a special type of dump car has been devised for this service.

One of these cars, as used at Cleveland, Ohio, is shown in Figs. 1 and 2. It is of steel construction, the underframe having two fish-belly plate-girder sills 24 in. deep at the middle. At each end are standards carrying a horizontal transverse perforated plate, the holes in which engage with studs on a cast-steel rocker on the end of the car body. The body is semi-cylindrical, made thoroughly water tight, and braced by three cross partitions which are perforated to allow liquids to find the same level throughout the car. It is supported on the end rockers and on three intermediate trains of rolls. It is provided with double covers, hinged at the middle and clamped to the top flange angle of the body when closed.

The body is held in position by side chains having the lower end attached to the sills and the upper end to a

FIG. 1. DUMP CAR FOR TRANSPORTING GARBAGE AT CLEVELAND, OHIO

(Orenstein-Arthur Koppel Co., Koppel, Penn., builders.)

shelf angle on the body. These are fastened with a shackle which can be disengaged readily. To dump and right the car, a crane or air hoist is used, its hook engaging a loop on the side of the body. Very little power is required, owing to the way in which the body is supported. The car is washed out with a hose when dumped, so as to remove any material adhering to it.

The cars are built with a capacity of 1450 and 1800 cu. ft., or 40 and 50 tons. The 40-ton cars are 37 ft. 4 in. long over the end sills, 30 ft. long inside, 10 ft. 1 in. wide over all, and 10 ft. 10 in. high. They have arch-bar trucks, and are built and equipped to conform to M. C. B. standards and the requirements of the Interstate Commerce Commission. The cars are built by the Orenstein-Arthur Koppel Co., of Koppel, Penn., and we are indebted to the company for drawings and information.

In regard to the garbage transportation service by rail, the city of Cleveland, Ohio, operates 14 cars in connection with its municipal garbage-disposal plant, two of which are of 50 tons capacity. Mr. Hobbs, City Commissioner, informs us that the haul is seven miles, over the Baltimore & Ohio R.R., which furnishes the locomotive for the work. The city pays the railway 15c. per ton for the haul, and in 1913 the service averaged 170 tons per day. The Public Service Department considers this the cheapest and most satisfactory method the city has been able to find for the removal of garbage to the disposal plant.

We are informed that the Standard Reduction &

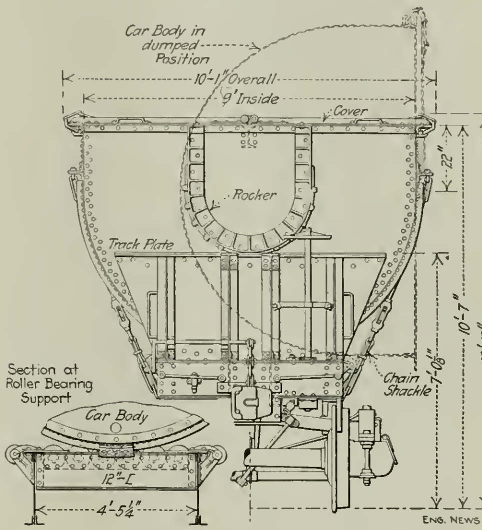


FIG. 2. DETAILS OF DUMP CAR FOR GARBAGE

Chemical Co., of St. Louis, has 18 of the cars in service; the city of Columbus, Ohio, has six, and the Garbage Reduction Co., of Toledo, has six. At Toledo, cars for this purpose were purchased by a former city administration to be used in connection with hauling garbage from a loading station centrally located. We are advised by Mr. McKechnie, Chief Engineer of the Department of Public Service, that on account of objections from property owners the loading station was never built and the cars were sold.

At Columbus, O., the garbage is collected in rear-dump wagons and hauled to a loading station, located in the central part of the city, where the wagons dump direct into the special garbage cars. The city has been operating four 40-ton dump cars and has purchased an additional 50-ton car, all of the type described above. The cost of these cars was approximately $1900 each. The garbage reduction plant is located about 3¼ miles south of the loading station. The cars are hauled two miles of this distance over the municipal railway track (built originally to serve the sewage disposal plant) and the remainder of this distance over the tracks of the Hocking Valley Ry. The railway delivers the loaded cars to the reduction plant and returns the empty cars to the loading station between 9:00 p.m. and 12:00 p.m. each day for a flat rate of $15 per trip, regardless of the number of cars handled. The above charge amounted to 25c. per ton of garbage hauled during 1912 and 21c. per ton during 1913.

The practice has been to load two cars each day. During the summer, however, the garbage averages nearly 90 tons per day and has reached a maximum of 130 tons,

so that the cars were becoming badly overloaded. The Department of Public Service now plans to use three 40-ton cars one day and a 50-ton and 40-ton car the next day. During the winter months, when the garbage amounts to about 55 tons daily, there is occasionally a day when no garbage is shipped. The average for the year 1913 was 72 tons daily. We are informed by John C. Prom, Assistant Engineer of the Department of Public Service, that the cars have proved quite satisfactory and the arrangement is much more economical than delivering the garbage all the way by teams.

Hauling City Waste on Street Railways at Chicago

The use of dump cars on electric street-car lines for hauling street sweepings and miscellaneous waste (but not garbage) is practiced in Chicago under the direction of the Bureau of Streets (Department of Public Works). This service was instituted in February, 1911, the refuse being hauled to abandoned clay pits in the northwestern part of the city. The loading station consists of an elevated platform at 15th Place and Loomis St., with an incline at each end, so that the wagons can be driven upon it and dump their loads into the cars, which stand on tracks on both sides of the platform.

The initial equipment consisted of six wooden dump cars and a motor dump car, each with a capacity of 36 yd. Six steel dump cars and an air-dump motor car have since been added to the equipment. The steel dump cars are constructed with three V-shaped buckets having a capacity of 10-yd. each, and a canvas cover is fitted over each car when loaded.

A train consists of three cars, including the motor dump car. The city of Chicago pays the railway company $25 per day for each motor and $6 per day for each trailer used, the motor being owned by the railway company and the trailers by the city. It is the intention to establish another loading station of this kind on Goose Island in the near future, and 12 additional steel dump cars have been ordered. For information as to the above we are indebted to Walter G. Leininger, Superintendent of Streets, Chicago.

A Spring Guard-Rail for Frogs

The frog guard-rail is a troublesome feature in track maintenance, owing to the severe service imposed upon it in holding (or forcing) wheels into proper line as they pass the frog. If the guard-rail is not secured to the track rail it will be forced away from its proper position by the continuous pressure and blows of the wheels, the flangeway being widened and the guard-rail rendered practically inoperative. If the guard-rail is bolted rigidly to the track rail, as is now general practice, the blows against it tend to pull the track out of line, and often result in the stretching and breaking of the attachments, besides causing severe wear on the frog point.

To meet these conditions a spring-cushioned attachment has been devised, using springs which are stiff enough to hold the guard-rail in place under normal conditions but which will yield slightly under heavy blows. The bolt is set at an angle instead of horizontally, so that the shock is taken directly at the head of the guard rail and transmitted to the base of the track rail. A lateral blow on the guard-rail will result in a partial upward reaction on the track rail, and this will be resisted by the weight on the wheel which delivers the blow.

The construction is shown in Fig. 1, and Fig. 2 shows a 15-ft. guard held by four of the spring-bolt attachments. The bolt *A* is long enough to carry the spring *B*, which is set up to the desired tension by the nut and bearing plate. The head of the bolt fits into a grooved block *C*, on the guard-rail, and the spring bears upon block *D*, which has a bearing against the head, web and base of the track rail. There is the usual spacing block *E*, between the rails, bored to fit the bolt.

Fig. 1. A Frog Guard Rail with Spring Attachments

We are informed, however, that the device does not meet with the approval of the railway engineers. They consider that it is wrong in principle, in that the guard-rail yields when it is needed to protect the frog point, and that a guard-rail should be held rigidly in its normal relation to the track rail. For this reason the one or two guard-rails which are in use have the spring action restrained by bolts.

This cushioned guard-rail is the invention of E. J. Shoffner, of Roanoke, Va., and has been in use at some turnouts on the Norfolk & Western R.R. for over five years. The maintenance work has been very little, none of the bolts show any stretching, and there has been but

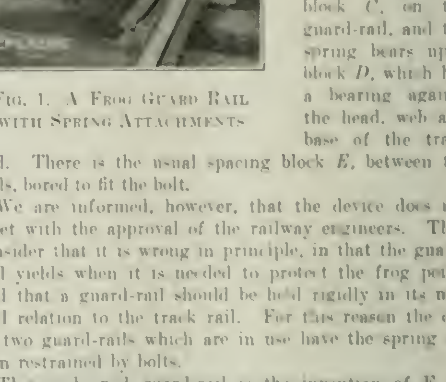

Fig. 2. A 15-Ft. Guard Rail with Four Spring Attachments

slight wear of either the guard rail or the frog point. We are informed, however, that the device does not meet with the approval of the railway engineers. They consider that it is wrong in principle in that the guard rail yields when it is needed to protect the frog point, and that a guard rail should be held rigidly in its normal relation to the track rail. For this reason the few spring guard-rails which are in use have the spring action restrained by bolts. In this connection mention may be made of

the Conley frog, in which the wheel is guided by the frog itself, dispensing with the ordinary guard-rails which guide the wheel through the medium of the axle and opposite wheel.

The spring guard-rail described above is manufactured by the Virginia Railway Supply Co., 500 Dickson Building, Norfolk, Va., and the company reports trial orders from other railways.

An Electric Air-Hammer Drill

The accompanying figures show the latest design of a type of electric drill that has been under commercial development, with considerable field service, for several years. The fundamental principle involved in the mechanism has been used in a line of electric coal-punching machines, though the idea of applying it generally antedates the application to coal mining. It was planned to make the development first for coal machinery, then for rock drills and finally for riveters, pile drivers, etc.

Electricity is used as the motive power but the blow is delivered to the drill steel by an air-actuated hammer descending on a dolly pin. The motor compresses the air in the drill cylinder and this is immediately expanded, in delivering the drilling blows, so that there is little dissipation of the heat necessarily developed in compression.

The mechanical action is seen in Fig. 1; on the forward stroke of the motor-driven compressing piston, air is admitted by an inlet valve on the compression space and follows the piston. On the return stroke this air is trapped and compressed. At the same time, atmospheric pressure below the hammer piston causes this to follow the compressing piston. When the latter on its up stroke uncovers the lower row of ports the compressed air escapes between the two pistons and in expanding causes the hammer to deliver its blow. At the end of the stroke of the hammer piston, a small port is uncovered and a small amount of air allowed to escape at slightly above atmospheric pressure, so as to prevent accumulating large air pressures between pistons.

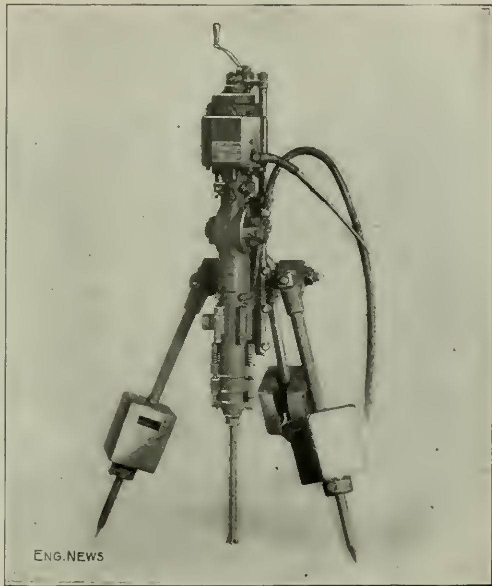

Fig. 2. Electric Air-Hammer Drill and Tripod Mounting

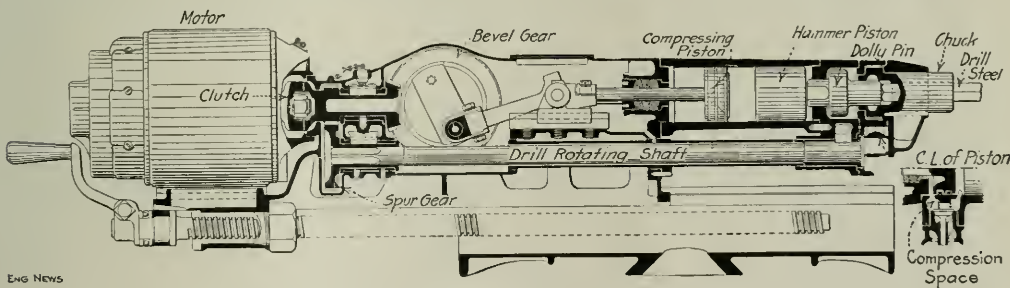

Fig. 1. Section through Electric Air-Hammer Drill

The design shown is fitted for the use of hollow drill steels and wash water continuously supplied. Water may be delivered from pressure lines if desired, but there is a small pump on the main-gear spindle and the discharge is piped to the drill-chuck chamber. The steel is rotated a fraction of a revolution after each blow, the chuck having a ratchet-and-pawl connection to a small crank arm on a long shaft running back to the motor gear, where it connects with the latter by spur pinion and gear.

Engine-indicator cards taken on these pieces of apparatus have shown an expansion curve lying close to the theoretical adiabatic line and indicating small heat losses. A maximum air compression of some 60 lb. per sq.in. is reached and, of course, heat is generated by this action the same as in any compressing machine. But the heat is absorbed by the immediate expansion and the only noticeable temperature is that of the cylinder walls resulting from absorption. This in no case exceeds 150° F. This latest type (3-in. cylinder and 3-in. stroke) is driven by a $2\frac{1}{2}$-hp. motor (direct- or alternating-current as desired) and this is claimed to draw only from $\frac{1}{5}$ to $\frac{1}{10}$ the amount of energy required for a distinct supply of compressed air to an air drill.

This machine is built by the Pneumatic Machine Co., Syracuse, N. Y., under the designs of Alexander Palmros, Chief Engineer.

FIG. 1. THE ELABORATE PILE FOUNDATIONS FOR THE BUILDINGS O

Soft-Ground Foundations, Panama-Pacific International Exposition

PENETRATION AND LOAD TESTS OF PILES

By L. F. Leurey*

SYNOPSIS—Heavy buildings to be erected on soft sand and mud—hydraulic-dredge fill. Continued subsidence of fill. Results of auger borings. Penetration and load tests of piles. Pile foundations adopted for a large part of the building area. Over 600,000 lin.ft. of pile driven at cost of 24½c. in place, 14c. delivered. This article is intended to supplement and elaborate on the articles on the Exposition by A. H. Markwart, Assistant Director of Works, ENGINEERING NEWS, Nov. 6, and Nov. 27, '13.

The site on which the Main Exhibit Palaces of the Exposition are located was originally a tidal flat of San Francisco Bay, with occasional deeper [illegible] that had been dredged out for wharves and anchorage for vessels. About twenty years ago, private interests received a grant of these tidal lands and built the rock sea wall which [illegible] the shore line on the map herewith. A large sand hill that overlay the site of the [illegible] was graded and the excavated material deposited over a large portion of the submerged area but the work was not carried to completion, and an area of water about [illegible] acres in extent remained to be filled by the Exposition.

The condition of the site when the Exposition took over the ground is shown approximately by the dotted [illegible] shown in Fig. 3A. [illegible] of this section was submerged, the average high-tide level being about Elev. [illegible] ft. and extreme high tide reaching Elev. [illegible], referred to San Francisco datum as zero. The average elevation of the submerged section of the site was about [illegible].

HYDRAULIC FILL; SUBSIDENCE*

The exposition company pumped 1,300,000 cu.yd. of fill into the submerged area. This brought the surface to Elev. —2.75 approximately. The fill material averages from 60% to 70% of sand, the remainder being mud and silt. Due to the superior weight and density of this material, it crushed its way 2 to 5 ft. into the soft ooze of the old bottom, to such extent that where the original soundings showed Elev. —15, the actual bottom of the dredger fill is nearer Elev. —20.

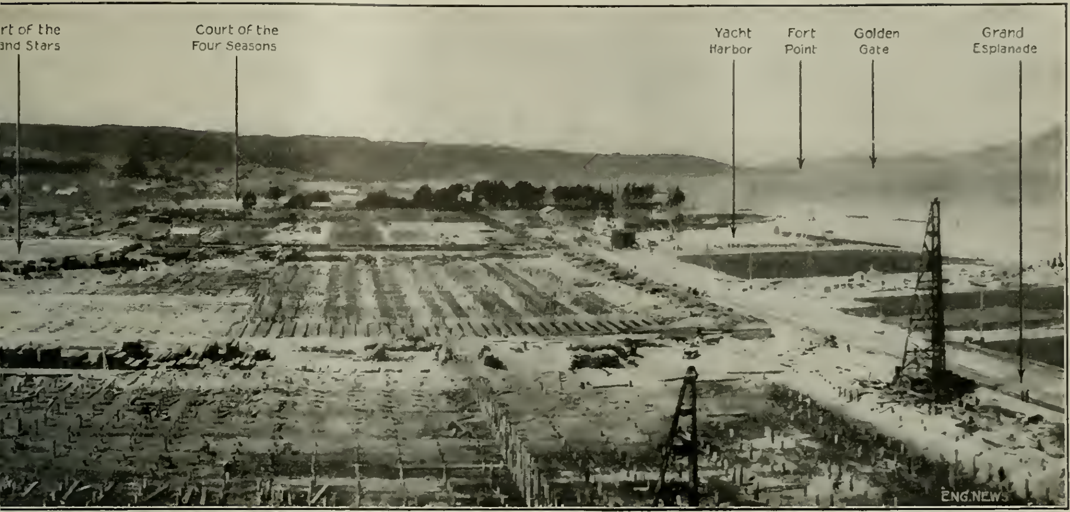
Due to the varied lines of flow of the dredger fill and its varying character, numerous "kolnays" or watery pockets were found in the fill. These kolnays often had skins of tight sand overlying them, but on driving in a long stake or pile their presence would be indicated by a geyser of water coming up around the pile and by the corklike action of the pile in floating up when relieved of the weight of the hammer.

*GENERAL CONTROL OF SETTLEMENT OF SITE—A. H. Markwart, Assistant Director of Works, states as follows concerning the settlement of the fill on the exposition site: [illegible]

[illegible]

[illegible]

*[illegible]



THE PANAMA-PACIFIC INTERNATIONAL EXPOSITION, SAN FRANCISCO

Shortly after the fill had been pumped in, settlement stakes were driven at various points within the filled area and levels taken at regular intervals. A typical curve of settlement is shown in Fig. 2. It will be noted that the initial settlement was rapid; this was, of course, expected. But it was not expected that the settlement shown by the latter part of curve would be so uniform and continuous.

Test Borings

After the fill had taken its initial rapid settlement, borings were made at the corners of all buildings of the main group. It was found that the soil was yellow beach sand overlying soft clay, or else blue dredger sand overlying blue mud and clay. Under the sites not occupied by the dredger fill, the clay is of a soft puttylike consistency and in some cases is mixed with sand; at the bottom of the clay stratum is a layer of 1 to 5 ft. of hard green sand and clay, and then yellow hardpan. Underneath the dredger sand, the same type of clay is found, but mixed with blue mud and water, and the same layer of green sand and clay and hardpan is encountered except along the north building line fronting the Bay: here the hardpan pitched below the limit of the boring tools, but was estimated from driven piles to be about 120 ft. below the surface.

The upper yellow-sand layer extends down from surface to a minimum of —18 and a maximum depth of —30. It is a clean, coarse, yellow or gray sand of uniform character. The dredger sand is much finer and more compact, and contains about 30% of silt, but due to its fineness and liquid character it has a powerful suction action on any material driven into it.

Some of the boring results are charted in Fig. 3. The locations of all borings are platted on the map in the same figure.

Pile Penetration and Loading Tests

The approximate character and stratification of the soil and the depth of hardpan being thus determined, it was decided to drive a number of test piles of various lengths to see what the supporting power of the ground was at different depths, because it was at once apparent that if every pile were driven to hardpan the cost would run into a very large amount of money.

The test-pile locations were selected as far as possible

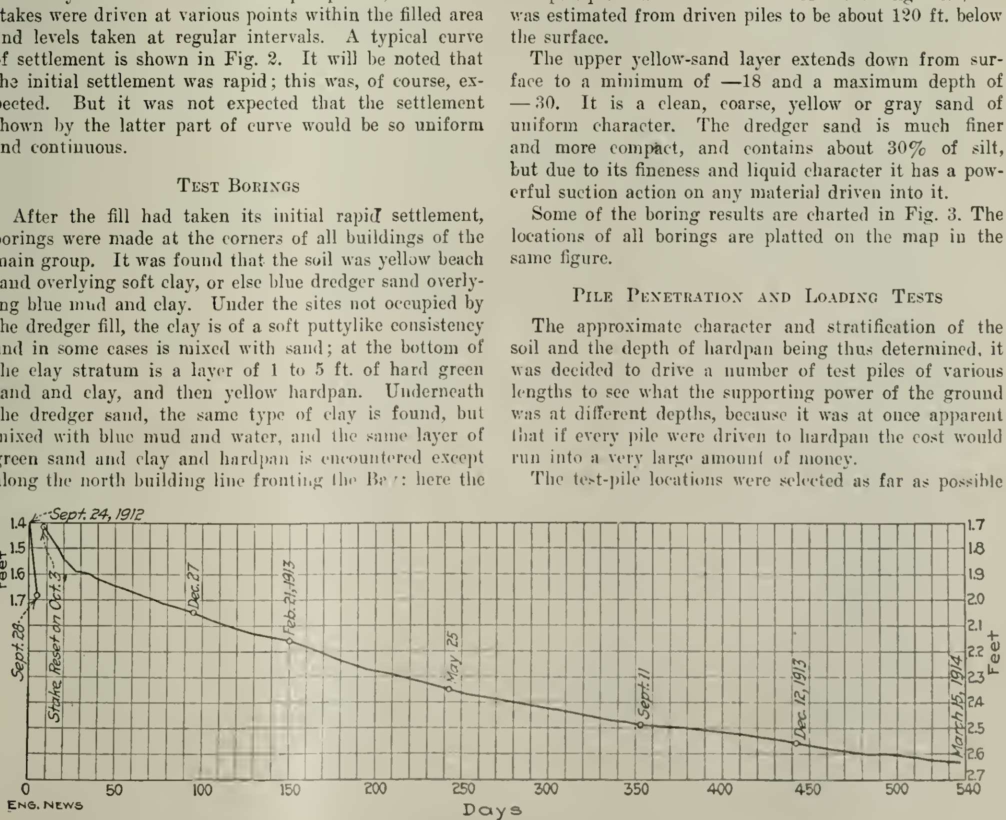


FIG. 2. SETTLEMENT DIAGRAM FOR STAKE 13

with a view to obtaining data primarily for the building itself and also for value of comparison with adjacent or similar areas in other parts of the grounds. The piles wherever possible were of the minimum size, so as to get the least favorable condition. They were loaded by means of timber sand-boxes (Fig. 5) to an ultimate load at least 50% in excess of what they were expected to carry. The loads were applied gradually, in batches, and no pile was loaded further while it was in the process of settling; the aim was to get the settlement of the pile at each stage of loading.

In driving the test piles, a 2700-lb. drop hammer was used, and the fall of the hammer was maintained at 10 ft. Records were kept of the number of blows required to drive a pile for each foot of its length underground; the results are given in Fig. 6.

THE DREDGER-FILLED AREA

The buildings roughly divide themselves into two groups. The first, consisting of the Varied Industries, Manufactures, Mines and Transportation Buildings, is in the area of the new dredger fill. The second consists of the Liberal Arts, Education and Food Products Buildings, which will rest on older fill or on ground which was unsubmerged at the time the Exposition took over the land. The Machinery and Agricultural Buildings are partly within and partly without the area of the new dredger fill. The Fine Arts Building, due to its concentrated loadings and the shallow depth of hardpan under it, was not considered in the pile tests, it being apparent that the proper course was to drive piles to a hard foundation.

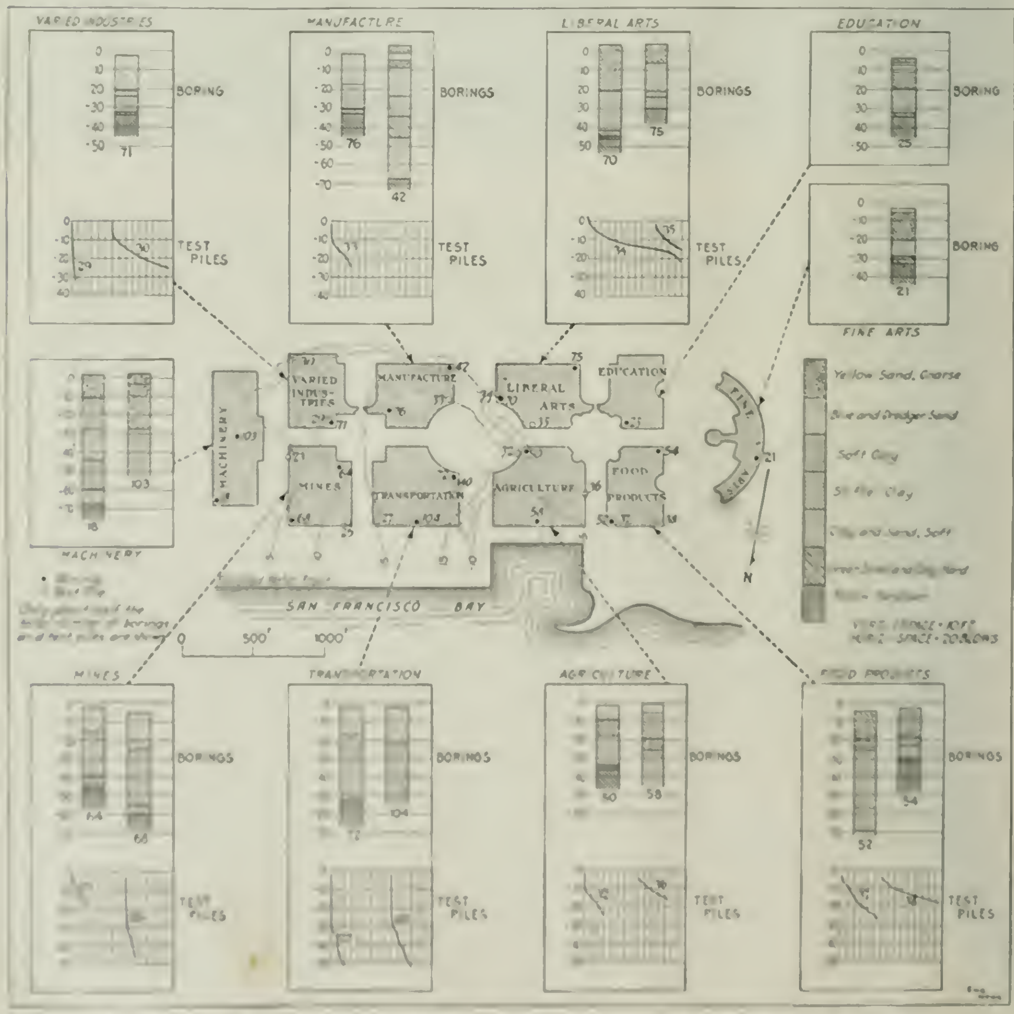

FIG. 6. TYPICAL TEST BORINGS AND TEST PILES, PANAMA-PACIFIC EXPOSITION GROUNDS

(... showing areas finally decided upon. Contours below site datum; M. H. W. is about —6.5 ft.)

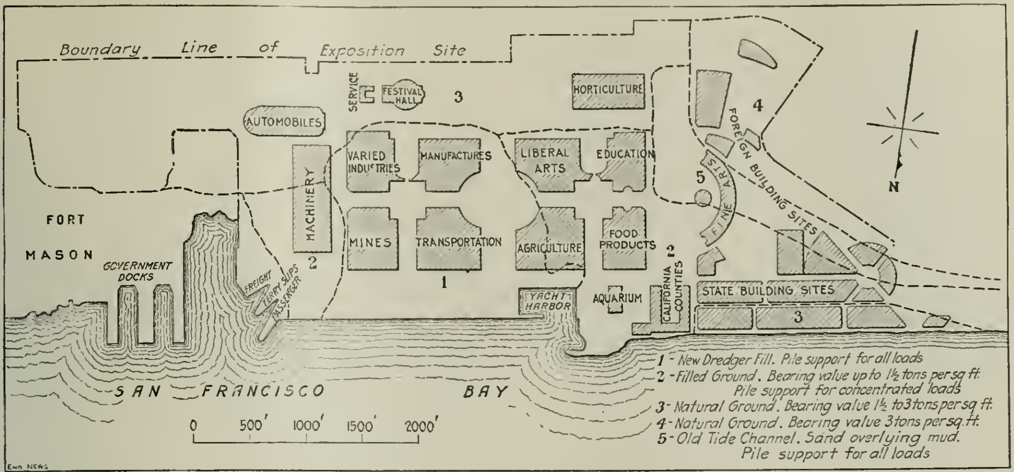

Fig. 4. Zones of Foundation Types, Panama-Pacific Exposition

It soon became apparent from settlement stakes and pile tests that the new dredger fill not only was non-supporting in character but was in addition *acting as a positive load on piles* driven into it or through it. After observing piles of various lengths and under various load conditions, it was deduced that, roughly, as much pile was required below the fill as there was driven through the body of the fill, to break the suction grip of the dredger sand. The question then arose how much piling was required below the fill to support the service load on each pile. Piles 45 ft. to 50 ft. below the surface seemed able to break the grip of the fill, but settled under the positive test load that was imposed on the pile.

Parallel tests were carried on by means of loaded platforms to get the supporting power of the dredger sand, and it averaged about 400 lb. per sq.ft. Of course, that figure represented the supporting capacity of the dredger sand relative to its own surface, since the whole fill was settling.

Decision of Board on the Transportation Building

At this juncture, the necessity arose for a definite decision as to the type of foundation to be adopted for the Transportation Building. Due to the very large amount of money involved and the necessity of feeling sure of the results to be obtained, an advisory group of consulting engineers: J. D. Galloway, C. E. Grunsky, C. Derleth, Jr., and C. B. Wing, was called in.

After studying very carefully the collected test data and witnessing the driving of four groups of piles in actual position on the building site, the board arrived at the same conclusion that the Exposition engineers had already tentatively formed, namely: That it would be unwise to attempt to carry the pile load on skin friction; and that it would be necessary to drive to a penetration of about 1 in. per blow of a No. 1 Vulcan steam hammer or its equivalent, obtaining this penetration in the hard skin of sand and clay that overlies the hardpan.

The driving of the four groups of long piles as recommended and witnessed by the consulting engineers showed that a penetration of less than ½ in. per blow could be reached with piles varying in length from 35 ft. to 75 ft., and that the intermediate ground offered practically no resistance to the penetration of the pile (in fact the weight of the hammer put all of these piles down for 35 ft. under the surface). To further confirm the latter opinion, Test Pile 28, at the southeast corner of the Transportation Building, on being loaded from 12 to 16 tons settled over 5 in. and continued to settle under a 20-ton loading until it pulled up on the hard green sand and clay—it had been originally driven to within 18 in. of this surface. It will be readily noted by referring to the penetration record, Fig. A, that this pile encountered practically no resistance to driving.

It was suggested at first to separate the floors from the building and carry them on platform foundations, but when it was considered that the relative value of the dredger fill for supporting loads was only 400 lb. per sq.ft., and that in addition some device had to be provided against the absolute settlement of the whole fill, it was finally decided to carry floors, tracks, walls and columns all on piling. The loathness of the engineers to accept what seemed inevitable, that is, long piles on this building, is explained by the fact that about 4500 piles, totaling 280,000 ft. below cutoff, were required for this building alone—for only ten months service.

The decision finally arrived at on the Transportation Building, substantiated by the tests made on the other sites within the area of the dredger fill, forced the conclusion that the same character of foundation must be obtained on these sites, and it was so decided to drive piling on the Manufactures, Varied Industries, Mines and on the affected portions of the Agriculture and Machinery Buildings into the hard, green sand and clay medium overlying the hardpan.

Eight months after driving the settlement stakes, the dredger sand was still continuing to settle at a uniform rate, amounting to an average of 1 in. per month. In places where there is a superposed fill, such as the 4-ft. fill for the Court of Honor, this rate has been increased to as much as 2½ in. per month for the first month after this fill was placed.

THE AREA OF ORIGINAL GROUND

For the building sites not affected by the recent dredger fill, comparative tests showed that it was at least as good (if not better) to rest the pile within the top layer of sand as to drive it through only a few feet.

As the result of all pile tests, it was determined to make the maximum service load of all piles 20 tons, and to determine the bearing power of short piles in the local sand formation. Six test piles were placed in the Education Building 14 ft. to 31 ft. below cutoff. All of these piles stood a load of 25 tons without settlement. The shortest pile of all, 14 ft. in the ground, was loaded to 20 tons without settlement. Seven other tests with short piles were conducted in ground of similar character (34 and 35 in Liberal Arts, 37 and 38 in Food Products, 41 and 42 in Machinery, and 36 in Agricultural Building), all of which confirmed the tests on the Education Building, namely: that short piles driven into and stopped within the sand layer of the old fill had ample factor of safety for carrying loads not exceeding 20 tons per pile.

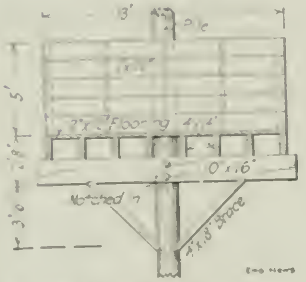

FIG. 5. SANDBOX USED IN PILE LOADING TESTS

The question might naturally be brought up that if the sand were capable of supporting short piles, it would also be capable of supporting spread footings. Spread footings were in fact considered, assigning to the sand a supporting value of 2000 lb. safe, which figure was determined from loaded-platform tests made on the site. Short piles, however, figured out cheaper, and possessed other advantages (simplicity of footing design, adaptability to all characters and elevations of surface), which finally led to the adoption of this type. It was thought also that pile footings in the territory of old or new fill would offer a better resistance in case of possible earthquake, as experience in the past indicates that structures were most affected when resting on filled ground by means of spread or raft footings.

The greatest observed settlement on any of these piles within the sand layer and loaded to 20 tons was $\frac{3}{4}$ in. It was consequently decided that piles should be driven into, but not through, the sand layer, for the Education, Food Products, Liberal Arts and such portions of the Machinery and Agricultural Buildings as were of similar character, for the support of concentrated loads. The decision to follow this procedure instead of driving through the substratum of soft clay resulted in the saving of a great many feet of pile.

FOUNDATION ZONES

After a general study of the pile tests, platform tests and borings coordinated with the information derived from studying the history of the site, the Zone Map, Fig. 4, was outlined. The zone areas thus established can naturally only furnish information of approximate character, this information being substantiated by local tests at all important building sites.

In this manner, it was decided to rest the Automobile Building on spread footings, 3 tons per sq.ft. safe.

The Festival Hall and Horticultural Building Sites were assigned a value of $2\frac{1}{2}$ tons per sq.ft., but it was decided to support the main dome of the Horticultural Building on piling.

The ground within the Concessions District has a high supporting value, and consequently requires no piling for the support of building structures. The States and Foreign Building Sites have a high average supporting value, but some piling is required in Zone 5.

The cost of the tests was very low, when compared to the total cost of foundation piling (see Tables I and II).

TABLE I. QUANTITIES AND COSTS OF FOUNDATION PILES, PANAMA-PACIFIC INTERNATIONAL EXPOSITION

Buildings	No. of piles driven	Lin. ft. piling driven	Lin. ft. piling cut-off	Piling below cut-off	Percentage of waste	Average length of pile below cut-off	Approx. cost per lin. ft. of pile below cut-off
Machinery	1,577	47,573	2,487	45,086	5.2	28.6	27c
Education	634	11,[illegible]	1,[illegible]	[illegible]	11.9	15.7	40
Manufactures	1,591	62,292	5,4[illegible]	[illegible]	8.7	35.7	25
Agriculture	1,374	59,710	[illegible]	[illegible]	3.8	41.8	23½
Food Products	665	12,015	2,388	9,627	19.9	14.5	40
Liberal Arts	751	10,980	1,241	9,747	11.4	13	40
Transportation	4,541	298,671	11,849	286,815	4.0	63.2	23
Fine Arts	1,051	31,111	4,173	[illegible]	13.4	25.6	2[illegible]
Varied Industries	1,444	52,467	2,756	49,611	5.2	34.3	22
Mines	2,026	98,463	4,600	[illegible]	[illegible]	[illegible]	22
Total	17,[illegible]			[illegible]		41.2	24½

Note—All piles were driven with No. 1 Vulcan Steam Hammers.

Weight of moving element approximately, lb.	[illegible]
Fall of hammer element approximately, ft.	[illegible]
Average cost of Douglas fir piles delivered at site, per lin. ft.	[illegible]
Approximate cost of erecting and dismantling per driver	[illegible]

TABLE II. UNIT-COSTS OF TESTS

(Total cost, including material, labor and engineering.)

Loading piles by means of 30-ton sandboxes, as shown in sketch, per test	$[illegible]
Loading platforms with sand load, per test	15
Hand borings with auger and 1-in. casing, holes 15 to 65 ft. deep in sand and clay, per lin. ft.	[illegible]

The results obtained were not only valuable in giving the engineers assurance in the use of short piling, but also reduced contractors' prices by furnishing them with accurate information, thus eliminating unnecessary waste.

✻

Grasses for Holding Earth Banks in Place—In maintaining earth fills or on the sides of cuts, hardy well rooted low growing grasses offer probably the best protection against erosion. In a recent issue of the "Service Bulletin" published monthly by the Iowa State Highway Commission, Ames, Ia., Prof. L. H. Pammel states that of the grasses developing a good system of root the following are the best: Hungarian brome grass (Bromus inermis), hairy brome grass (Bromus marginatus), Canadian blue grass (Poa compressa), blue grass (Poa pratensis), fescue grass (Festuca pratensis), western wheat grass (Agropyron Smithii). Quack grass produces good roots but its use is not to be recommended because it spreads freely to the fields.

One difficulty with the Hungarian brome grass is that it is not so good on the south or sunny slope of the hills because the hot rays of the sun interfere with the germination and growth of the grass. On the sunny slope western wheat grass or Canadian blue grass can well be used.

Planting on cut sides is another problem, and experience seems to indicate that some of the legumes will succeed better than the grasses, as it is always difficult to get the grasses to start. Sweet clover or creeping honeysuckle is very good for the sides of cuts.

Experiments have shown that all the vegetation of this type is easily killed by cultivation and that there is little fear of its spreading to the fields.

Tests of the Resistance to Corrosion of Various Brands of Iron and Steel

The Water Service Committee of the American Railway Engineering Association has been engaged for two years past on a series of tests to determine the relative resistance to corrosion of various samples of iron and steel. The results of these tests are of especial interest in view of the widely published claims concerning the resistance to corrosion of certain brands of iron and steel of special chemical composition.

The tests have been carried on under direction of J. L. Campbell, Engineer of Maintenance-of-Way, of the El Paso & Southwestern Ry., who is Vice-Chairman of the Water Service Committee. A report of these tests was presented at the annual meeting of the American Railway Engineering Association in March, and was briefly summarized in our report of that meeting. Since that time, the tests have been continued so that the results are now available from a twelve-month exposure of the various samples. These results, as will be seen by reference to the tables, indicate that corrosion proceeds at a substantially uniform rate on all kinds of rolled iron and steel, no matter what its chemical composition. We print the report below, as follows:

The resistance to corrosion of iron and steel plates has been the subject of considerable study and discussion by the Water Service Committee for several years with the view to determining the most suitable and most lasting material for steel water tanks. Following is a report prepared by J. L. Campbell, Vice-Chairman of the Water Service Committee, on a series of tests of various metals conducted by him, outlining their relative resistance to corrosive influences:

In the tests beginning May 1, 1913, seven samples of iron and steel were selected, as follows:

No. 1, Charcoal iron.

No. 2, Openhearth steel.

No. 3, Openhearth steel containing 0.40 per cent. of copper.

No. 4, Openhearth steel containing 1.00 per cent. of copper.

No. 5, Ingot iron.

No. 6, same as No. 3, except as to preliminary surface preparation as hereinafter described.

No. 7, same as No. 4, except as to preliminary surface preparation as hereinafter described.

Each sample contained four pieces. The samples were each ⅛ in. thick, 2 in. wide and 2 to 3 in. long.

In the following analysis, the figures in the first column are as given by the manufacturers, and in the second column, as given by S. W. Parr, Professor of Applied Chemistry, under the direction of A. N. Talbot, Professor of Civil Engineering, University of Illinois.

No. 1, Charcoal iron.

The sand, clay soil, alkali soil and the cinders were placed in aluminum pans, each pan being 4 in. deep, 11 in. wide and 16. in. long in the clear. The pans are numbered 1, 2, 3 and 4 and the settling tank at Douglas, No. 5, corresponding to the numbers designating the corrosive mediums contained by the pans. These pans are kept on the balcony of one of the south windows of the seventh floor of the office building of the El Paso & Southwestern R.R. Co., El Paso, Tex. They are exposed to sunlight and air, and the materials in them are periodically saturated with water, thereby being alternately wet

and comparatively dry, simulating in a general way service conditions of iron and steel buried in the ground with a light covering.

In each pan, one piece of each sample of iron and steel, No. 1 to No. 7, inclusive, is placed, with the exception of pan No. 5 at Douglas, in which samples Nos. 6 and 7 were not placed. The pieces are buried in the corrosive medium by forcing them down edgeways to the middle of the depth of the pan, the pieces standing side by side about two inches apart. As this places one piece of each sample of iron or steel in each pan, it makes the corrosive test strictly comparable throughout for all the corrosive mediums.

Each piece of each sample of iron or steel was prepared for beginning the test by carefully filing off all surface oxidation until only clean bright metal showed over all surfaces of the pieces, including the edges, with the exception of samples Nos. 6 and 7. The original surfaces of samples Nos. 3, 4, 6 and 7, containing copper, were covered with a distinct copper-colored oxidation. The oxidation was left on Nos. 6 and 7 to determine its effect in resisting corrosion as compared with samples Nos. 3 and 4, from which the surface oxidation was completely removed before beginning the tests.

After being prepared as above, each piece of each sample was weighed on a metric scale measuring to one centigram. All pieces of all samples were then immediately immersed in the corrosive mediums as described. At the beginning of the test it was decided to clean and weigh the samples at the end of each three months' period, and the loss in weight in grams per square inch of exposed surface was chosen as the unit for corrosive comparison.

It has been found that the corroded samples may be thoroughly cleaned of the corrosive action, leaving the clean metal, by immersing the samples in a 10% solution of ammonium citrate, and this method of cleaning has been adopted. In this connection, and at the first cleaning, a clean piece of [illegible] iron was also immersed in the solution in order to determine if the latter itself would produce any loss of weight in the metal. Subsequent weighing of this control piece shows that there is no such loss, and the ammonium citrate appears to be a satisfactory medium for cleaning.

In the following tables, the corrosion is measured in loss of weight in grams per square inch of exposed surface and edges, as follows:

PAN NO. 1. CLEAN SAND

Sample No.		Loss in grams per sq. in. of exposed surfaces and edges: In 3 mo.	In 6 mo.	In 9 mo.	In 12 mo.
1	Charcoal iron	0.41	0.86	1.35	1.73

PAN NO. 5. WATER IN OVERFLOW TANK FROM WATER JACKETS

Sample No.		Loss in grams per sq. in. of exposed surfaces and edges: In 3 mo.	In 6 mo.	In 9 mo.	In 12 mo.
1	Charcoal iron	1.68	2.188	2.83	3.13
2	Carnegie plain O. H. steel	1.62	2.172	2.76	3.04
3	Carnegie 0.4% copper O. H. steel	1.82	2.310	3.16	3.32
4	Carnegie 1.0% copper O. H. steel	1.77	2.275	3.02	3.28
5	Ingot iron	1.39	1.880	2.65	2.93
6	Same as No. 3 not filed				
7	Same as No. 4 not filed				

Your attention is directed to results on samples Nos. 6 and 7 in pans Nos. 1 to 4, inclusive, from which it appears that the copper oxidation on the surface, as compared with the identical samples Nos. 3 and 4 but with the oxidation removed from the latter, protected samples Nos. 6 and 7 for three months, but this protection appears to have disappeared at the end of six months.

Perhaps the most significant figures are those showing the relative corrosion of samples Nos. 2, 3 and 4 as they are of the same grade of steel, made by the same manufacturer and are presumably identical in quality, the difference in copper content excepted. In regard to the addition of the copper, we quote from the letter of the manufacturer, as follows:

> In regard to the addition of copper, would say that the heats are made up as far as possible with copper scrap and any deficiency in the copper content is made up by adding the requisite amount of metallic copper to the bath in the open-hearth furnace about fifteen minutes or half an hour before tapping. The copper, therefore, has ample opportunity to become evenly distributed in the steel, particularly by the mixing action which takes place when the steel runs from the surface into the ladle.

It will be observed that the corrosion of the ingot iron is substantially the same as the other samples except in pan No. 5, containing the water from the overflow tank of the furnace water jackets at Douglas, Ariz. Of this water, Mr. Stuart W. French, General Manager, Copper Queen Consolidated Mining Company, says: "We have found that the water is extremely corrosive in our water jackets up to a temperature of say, 150° F. Above that temperature it seems to have little action. It is good water for our boilers, but in all cold-water pipes and water jackets where the water is more or less cool, pitting action is very strong."

The analysis of this water is given above. The steel water jackets of the furnaces mentioned require frequent renewal on account of the corrosion specified by Mr. French. It was for this reason that this water was also selected as one of the corrosive mediums in this test. The corrosive action of this water appears to be somewhat similar to that of an acid, and it will be observed that, while the corrosion of the ingot iron in the other corrosive mediums is not materially different from the other samples, it shows considerably less corrosion in the water, which conforms with its known ability to resist the sulphuric acid test.

The corrosion of all samples in the clean sand is greater than in the clay and alkali soils. Rather the reverse would be expected, especially in the alkali soil. This may be partially due to the fact that, while the sand is porous and allows a comparatively free circulation of air, the clay and alkali soils are very close-grained and practically exclude the air.

Tar Treatment of Macadam Roads in Lytham, England—Tar painting has been carried out in Lytham for the past nine years, this town being probably the first in the North of England to adopt it. Some [illegible] of the road along the sea front, which was an ordinary macadam road, were tried experimentally, half with limestone and half with granite chippings. The portion laid with limestone was for a time almost as dusty as ordinary macadam, but the granite being a harder material than the limestone, was practically lifeless when put [illegible] [illegible] but granite has since been used for tar-painted roads. When tar painting a new road an ordinary [illegible] tar boiler is used, which is [illegible] into a sprinkler with one [illegible] perforated to form a spray, but for repairs a small [illegible]-gal. boiler fitted with a pump and movable spray is chiefly used. A distilled tar is used for all [illegible] work, and for tar painting 1 part distilled tar to 1 [illegible] of crude tar. The tar macadam is better if it can be "[illegible]" for some time before laying, but in [illegible] [illegible] in handling [illegible] tar is put on the roads the same day that it is [illegible]. The tar-macadam used is composed of stone from [illegible] in. down to [illegible] in. and this macadam has been used long before a [illegible] [illegible] [illegible] [illegible] this method. [A. J. [illegible], Surveyor of Lytham, in the "[illegible] Journal," July 1.]

Editorials

The studies and experiments on which the design of the Panama-Pacific foundations was based, are probably as extensive a set of soil and pile tests as has ever been made. They testify to the prudence and skill of the engineers in charge of the exposition. Sound construction and maximum economy were secured. Erecting the great Exposition buildings on the yielding surface of a new sand-and-mud fill was in every respect a formidable task.

These tests are among the landmarks of a new spirit in foundation work. The future is to be a time when tests—both experimental tests and proof tests—will be the regular thing in foundation practice. The most advanced engineers have already come to this point. To guess at the bearing power of soil, or to "determine" the capacity of a pile by a mathematical formula, is a crude way to reach safe and economical results.

An Ancient Error

Heavy indeed are the responsibilities of a technical editor! A correspondent this week calls our attention to an error in a formula published in our issue of Nov. 17, 1892—22 yr. ago! The formula was the famous ENGINEERING NEWS piledriving formula, originally developed by the late A. M. Wellington in ENGINEERING NEWS, of Dec. 29, 1888. Discussing a formula for piles driven with steam hammers in the later issue referred to, Mr. Wellington gave the formula as

$$L = \frac{2\,WH}{s + 0.1}$$

and wrote:

> The same results will be reached if we retain the formula of par. 8, but let h = the total fall in feet in 10 blows, and S = the total set in inches in 10 blows.

Unfortunately, Mr. Wellington's handwriting was not of the plainest. His "S" looked more like a figure 5 than an S and the compositor set it up as 5. The error was undiscovered by the proofreaders and thus was handed down to posterity.

Fortunately, the remainder of the article made the error so obvious that probably none of the many engineers who have studied that editorial discussion have been seriously misled by the error. It is, however, an excellent illustration of the extent of the long continuing responsibility that the error of an editor, or even of a compositor, may make trouble long after those originally responsible for the error have passed away.

Signs to Mark Street-Car Stopping Points

In these times, when the managers of public-utility companies realize as never before the importance of cultivating the good will of their patrons, it seems worth while to again call attention to the system in use in German cities of plainly marking the places where street railway cars stop.

In American cities, it is customary for street railway cars to stop at or near every street corner to take on or leave passengers, but it is a constant bone of contention as to whether the stop should be on the near side or the far side of the street, and whether directly at the street crossing or beyond it, and how far beyond it.

Not only does the practice as to near-side or far-side stop vary in different cities, but it varies in the same city at different crossings. Furthermore, every little while a new city government or new management of the railway company upsets established customs and habits and changes the stop from the near side to the far side, or *vice versa*. The net result is that it is always a matter of doubt where a street car is going to stop. There are short streets and alleys in most of the older cities where a car may stop and may not.

Now when a man or woman stands on the street corner, often after having waited some time, makes frantic signals to a street-railway car to stop and then sees the car speed past, the motorman and conductor either paying no attention whatever or waving with a more or less derisive gesture at the other corner or some other place—when an incident of this sort occurs (and it probably occurs several million times every year in American cities) the would-be passenger, unless he is a person of most unusual good nature, is filled with indignation. In most cases he is ready to curse the street-railway company and all its works and workmen. What is particularly aggravating is that every such occurrence is supposed to testify to the ignorance or stupidity of the would-be passenger and he resents this as injustice. Henceforth he has it in for the street-railway company whenever he can get back at it with a vote at the polls or in the jury box. The chances are that he will vent a part of his disgust and irritation upon the motormen and conductors thereby adding a quite unnecessary increment to their contempt for the traveling public.

It would be easy to eliminate all this waste of human energy in useless anger and friction by adopting the simple plan common in every German city of having plain, neat, metal signs placed along the streets locating the points at which street-railway cars stop.

It would of course be impossible in old world cities, with their heterogeneous street arrangements to stop street cars at every crossing. Nor is there anything unreasonable in requiring a street-car passenger to walk three or four hundred feet along the street to a stopping point. He will be more than compensated by the greater rapidity of his journey once he is on the car. American street cars, in fact, stop too frequently for either the public convenience or the company's profit. With stopping points 800 ft. apart, the maximum distance a passenger has to walk along the street to a station is only 400 ft., and the maximum number of car stops per mile is only 6½.

Increasing the average speed of a street car increases its daily mileage and earnings. This is only one of the many directions in which American street-railway managers might profitably study foreign practice.

Questionable Taste in Publicity

From a recent trade publication we clip the following paragraph:

> McLean County, Ill., had a unique celebration on Good Roads Day, Apr. 15, 1914. It was a mock burial of inferior culvert materials.
>
> A concrete monument typifying the material and permanence of the concrete culvert, which will be used in future work, now stands above three graves in which were buried three old sections of culvert types which are no longer considered serviceable.
>
> While the mock burial was only a bit of fun indulged in by the County Highway men, yet it had a real meaning for the taxpayers. It meant that no more of their funds are to be expended in such a way as to require constantly recurring repair charges.

This "bit of fun" is similar to that indulged in by a prominent cement company at the last Cement Show, where one booth was given over to the funeral trappings of many satin-lined and glass-topped "coffins" in which were displayed cement sacks ruined, or to continue the morbid metaphor, "killed" by various forms of bad practice.

It seems to us that it takes a most peculiar sort of mind to see anything funny in death and particularly in the depressing accompaniments of modern burial.

Cleveland's New Municipal Electric Plant: Selling Electricity at a Three-Cent Maximum Rate

Cleveland has become famous as the only city in the country where a three-cent street-railway fare prevails. It is shortly to become equally noted as the only city in the United States—or anywhere else for that matter as far as we are aware—where a municipal electric plant furnishes electric current at a *maximum* rate of 3c. per kw.-hr.

Ever since the beginning of the electric-lighting industry, the rate of 10c. a kw.-hr. for current has had something of the dignity and standing that the five-cent fare has had in street-car service. While a higher rate has prevailed and still prevails in many places, there are very few places where a lower rate has been put in force.

In the early years of electric lighting, it is probable that a good share of the companies lost money at the 10-cent rate. The equipment was inefficient and the load factor was very low, when almost the sole use of the current was for lighting. Further, the amount of current used for lighting was very small compared with what present customs require.

In the last dozen years, however, great changes have come in the electric-lighting industry. We need not here take up these further than to say that their net result has been to cut down very greatly the cost of generating and distributing electric current when it is done on a very large scale. Of equal or greater importance than the reduction in the cost of making and distributing current has been the growth in the market for it, and especially in the demand for current for operating motors and heating appliances, which are in use during hours of the day when the station would otherwise be run on very light load.

These changes have been recognized by the electric-lighting companies and they have in almost all cases put in force heavy reductions in rates to *large* consumers of electric current. A sliding scale for the sale of current prevails almost everywhere; but the old price of 10c. is the base price in most general use and is the rate which the individual householder is obliged to pay for his electric light.

Now comes the City of Cleveland with the proposal not only to sell the individual householder electric current at 3c., but to make sweeping reductions from this base rate to the larger consumers, so that manufacturers and others who wish very large quantities of current for motor service can buy it as low as 1c. per kw.-hr.

No wonder that Cleveland and its city government are being cursed throughout the electric-lighting industry! For if Cleveland shall succeed in demonstrating that the city itself can make and sell electric current at such a low rate, it will give an enormous boom to municipal ownership of electric-lighting plants. Besides this, the success of such a demonstration would inevitably compel a reduction in rates for electric current sold by the companies not only in Cleveland but the country over. And it will have to be a sweeping reduction.

The question whether the Cleveland municipal electric plant can sell current at the proposed rates and make a fair profit, therefore, is not a merely local matter, of interest to Cleveland only. It is of interest to cities and city officers the country over and to engineers who have to do with municipal work and with electric lighting and power development.

Of course the final answer to this question must be given by the test of experience. Cleveland's new municipal electric station has just begun operation and six months or a year hence figures for its operating expenses will be available. A year or two years or even longer, however, will probably pass before the station load will be fully enough developed to enable high economy to be realized, and for the full realization of the changes to grow out of the Cleveland experiment because of the increased use of electric current, resulting from the low prices, one must wait probably years longer.

But without waiting for the final test of experience, it is of interest at this time, to ascertain the reasons why the Cleveland city officials in charge of the new municipal plant believe that they can carry out their great experiment with financial success.

It will, of course, be agreed by all that a municipal electric plant—or any other municipal enterprise for that matter—should be run on a business basis. That is, it should pay its way and pay the whole of its way, and not be a burden on the taxpayers. Rates for electric current should be such as will pay not only all the expenses of operating and maintaining the plant, but a sufficient sum in addition to cover the interest on its cost and an annual allowance for depreciation which will cover wear and tear and all other conditions, and when the plant is finally worn out or obsolete should be sufficient to replace it or to pay off the bonds issued for its construction.

If any municipal enterprise falls short of this, the deficiency must in the end be made good at the expense of the taxpayers.

It should be understood in the first place that the municipal electric-lighting business is not a wholly new experiment for the city of Cleveland. The city in fact fell heir to two complete municipal electric-lighting plants when

it absorbed two smaller municipalities a few years ago, the outlying suburbs known as Brooklyn and Collinwood. The Collinwood plant may be dismissed without further mention, as it is of very small size, so small that its operating cost per unit of power output is very high. The Brooklyn plant, however, has been in operation for a dozen years. Begun in a modest way in 1902 from the proceeds of a bond issue of $30,000, it has been added to year by year until its book value at the present time, including, of course, both the station and the distribution system, is $435,000 in round figures.

This book value has been reached by the rather uncertain process of adding to the original cost of the plant the sums spent on its enlargement and extension and deducting about 20% for depreciation. We are, however, informed that if the whole plant were appraised on the basis of what it would cost to replace it, including land, buildings, machinery, distribution system and all, the result would probably equal the book value above quoted.

Further than this, if the Brooklyn plant were appraised on the basis of its earning power—a basis so generally favored by the electric-lighting companies for their own plants—the fairness of the book value of $435,000 above quoted would be sustained.

The Brooklyn plant in 1913 sold current of a total value of $185,698. Its total operating and maintenance expenses were $116,719, leaving net earnings of $68,979.

THE NEW MUNICIPAL ELECTRIC STATION OF CLEVELAND, OHIO

It will be seen that these net earnings were equivalent to nearly 16% upon the book value above quoted of $435,000.

This Brooklyn plant, it should be especially noted, did this business and made this handsome profit at rates which, though not so low as those soon to be put in force by the new Cleveland plant, are phenomenally low compared with those usually charged by electric-lighting companies. *The average rate for all current sold by the Brooklyn plant last year was only 3.28 cents.*

The Brooklyn generating plant, however, is to be discontinued when the new municipal plant is in operation, for the cost of generating current will be so much lower there that it will no longer be profitable to operate the Brooklyn plant.

The abandonment of the Brooklyn plant is not expected to involve any considerable loss, for the distribution network and substations will be used as before, part of the machinery will be transferred to the new municipal station and the real estate will be salable.

And now let us take up the question, what will it cost Cleveland to generate and distribute current from the new municipal plant?

It will be admitted in the first place, of course, that the cost of current at the station busbars can be predicted in advance very closely. It is well known that electric central stations of large size using moderate-cost coal are today generally running at a total operating cost of less than ½c. per kw.-hr. of current output and often considerably below this figure.

The new Cleveland municipal electric plant is to begin operations with three turbine-generator units, each of 7500-kw. capacity. An additional unit from the Brooklyn station increases the total station capacity to 25,000-kw. It receives a supply of condensing water from one of the city pumping stations close by. Its machinery equipment represents the latest practice in steam boilers, turbines, electrical equipment and auxiliaries.

A full description of the equipment of this new station, which comprises many novel features in steam-power plant practice, is to be given at the December meeting of the American Society of Mechanical Engineers by Frederick W. Ballard, Commissioner of the Cleveland Municipal lighting department and engineer in charge of construction of the new plant. A detailed description of the plant is withheld until that time.

We can testify, however, that the station design and equipment is such that its operating cost should be at least as low as that of other first-class central stations. Large boilers, automatic stokers and cheap coal supply are among the important factors in keeping down the cost. It will certainly be on the safe side to assume that the total cost of current at the station busbars when the station is fairly loaded, including all outlay for operation and maintenance will not exceed 4 mills per kw.-hr.*

How much should be added to this for fixed charges (interest and depreciation) on the station cost? Here again we can figure very closely.

Interest on the city bonds issued to build the plant may be taken at 4½%. A 5½% depreciation charge or sinking-fund charge (it makes no difference which it is called) will certainly be ample to replace the plant well before it becomes worn out or obsolete, as it would be sufficient to pay off the principal in about 14 years.

Assuming the total cost of the power plant including land and building at $50 per kw. of capacity (which is close to the actual figures) we have annual fixed charges

*A valuable and authoritative statement on the cost of power development with present economical machinery is given by Mr. H. E. Longwell, Consulting Engineer of the Westinghouse Machine Co., in a paper published in the "Journal of the American Society of Mechanical Engineers" for July. We quote the paragraph as follows:

"As regards the cost of power: If one is satisfied with investment charges of 10½% per annum, if he can buy really good coal at not to exceed $3 per ton, if he is a capable manager and a careful operator, and reasonably economical, he ought, with a plant of 6000- to 9000-kw. capacity size, to be able to produce a kw.-hr. at the switchboard with substantially 100% load factor, for around 1.3 mills."

The new Cleveland municipal plant will obtain its coal at a cost of less than $2 per ton, and its capacity is 25,000 kw. Both these factors will operate to reduce its operating expenses below the figure set by Mr. Longwell. On the other hand, of course, the plant does not operate with a load factor of 100%.

Since Mr. Longwell includes the fixed charges in his final figure of 4.3 mills it is evident that our estimate of 4 mills as the operating cost of the Cleveland plant with its advantage of cheap coal and large size units is too high.

per kw. of capacity = 10% of \$50 = \$5. Let us further assume a load factor of $33\frac{1}{3}$%, giving an annual output per kw. of capacity of $\frac{365 \times 24}{3} = 2920$ hr.. Then \$5 divided by 2920 = about 1.6 mills.

Adding these fixed charges to the station-operating costs, we have a total cost of 5.6 mills for current at the station busbars.

And now what will it cost to distribute this current to the customers? Here we are on more difficult ground. The electric-lighting companies admit that the current which they sell the customer for 10c. costs them less than half a cent to produce in their stations; but they claim that the cost of distribution and sale is such that the 10-cent rate leaves them no more than a fair profit. But where are the actual figures of distribution cost to back up this assertion? Such figures appear to be jealously guarded.

Fortunately, Cleveland has experience enough of its own to serve as some guide in estimating these costs, for its Brooklyn municipal plant has now been in service for a dozen years.

As we have already noted, this Brooklyn plant, small in size and inefficient compared with present-day practice, nevertheless actually sold current to its customers last year at an average price of only 3.28c. per kw.-hr. and at this low rate earned a profit of 16% upon its book value.

Analyzing the operating expenses of the Brooklyn plant last year, we find that the total operating cost of both generation and distribution for the Brooklyn plant last year was 1.49c. per kw.-hr. and of this the station cost was 0.79c., leaving 0.52c. as the cost of distribution alone. This, however, was for current generated. The loss in distribution increases this to about 0.67 per kw.-hr. actually sold.

Now, it will certainly be agreed that a plant several times the size of the Broklyn plant can reduce the cost of distribution considerably below the figure quoted above. Let us be on the safe side, however, and assume that it will cost substantially the same or in round numbers 0.[illegible] per kw.-hr.

Next, what should be estimated for fixed charges on the distribution plant? The book value of the distribution plant in connection with the Brooklyn system is in the neighborhood of \$100 per kw. of station capacity. Probably a considerably higher figure should be assumed for the cost of a new distribution system, as a large part of it will have to be underground. On the other hand, while the amount of capital required for an underground system is much greater than for overhead wires, the percentage of cost required to cover maintenance and depreciation is much less. To be on the safe side, however, we will assume for the distribution system to be installed for the new Cleveland municipal plant an average cost of \$150 per kw. of capacity. Assuming the same interest and depreciation rate (10%) and load factor ($33\frac{1}{3}$%) that we assumed to find the fixed charges on the power station, we have \$15 ÷ 2920 = 5.13 mills.

Summarizing now the several items, we have the following as the total cost per kw.-hr. of output:

	Cents
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
	1.[illegible]

This is the figure for current at the station busbars. If we assume a 20% loss in the distribution system, then the cost of current at the consumer's meter will be 1.96c.

Low though this figure may seem to be, we believe it is conservative and further that there is reason to believe the actual cost may be reduced below even this figure. The load factor, for example, may be 40% or more instead of the $33\frac{1}{3}$% we have assumed, and this seems especially likely with the low rates made for large amounts of current for factory use.

It may seem on the face of the figures that the low rates of 1c. to 2c. per kw.-hr. for current to large users would result in a loss; but the cost to be figured against such consumers is chiefly the station-operating cost, since these customers use current at a time when the station and distribution system would otherwise be idle. The cost of distribution to such consumers also is generally very small.

Of course, only the test of final experience will determine what will be the average price received for the current sold, and, of course, this average price must be in excess of the 1.96c. found above for the average cost of current delivered to make the new municipal plant a financial success.

We may test the accuracy of these estimates also by comparison with the actual results in the Brooklyn plant. In this plant last year the entire operating cost of generating and distributing current was 2.06c. per kw.-hr. sold, and the allowance for interest and depreciation raised the total cost to 2.59c. If a 2500-kw. plant of out-of-date design can do this, it seems not unreasonable to expect that a 25,000-kw. plant operating with the high efficiency now obtainable will reduce this cost to 1.96c. The saving in station cost alone which will certainly be effected (the Brooklyn station cost last year was 0.97c. per kw.-hr. at the station busbars) would alone be nearly sufficient to reduce the cost as much as the estimate above given.

And if the Cleveland plant can deliver current to the consumer's meter at a total cost, including ample allowance for interest and depreciation, of 1.96c.; the prospects of the success of Cleveland's great experiment certainly seem favorable. The announced rate for the sale of current from the new station is 3c. per kw.-hr. Reductions from this are made only to consumers having connections of more than 10-kw. capacity. The flat 3c. rate will apply therefore to practically all private residences and all small stores and shops as well. The consumers who will benefit by the sliding scale and purchase current at less than a 3c. rate are nearly all of them purchasers for power rather than for light.

It must be remembered, of course, that before the cost can be reduced to this figure, the station must secure a load substantially equal to its capacity and with sufficient power customers to raise the load factor to substantially the figure of $33\frac{1}{3}$% assumed above.

The flat rate of 3c. per kw.-hr. will certainly be attractive to all those using current for residence lighting, but the users of current for power already have very low rates from the Cleveland Electric Co., and this part of the business will have to be fought for. The crucial question for the Cleveland plant will be whether its reductions from its maximum rate to power users will so cut down

the average return that it will fall below the average cost of production and distribution. The managers of the Municipal plant have certainly showed shrewd business ability in so simplifying their rate schedule that the average consumer can understand it and know in advance the price he will have to pay. This feature alone will help to bring them customers.

It is said by the critics that Cleveland's municipal electric plant is a shrewd political move of Mayor Baker. To cut the cost of electric current to thousands of householders is an achievement which will surely add greatly to the popularity of the administration. We believe the managers of private companies selling electric current will do well to study the Cleveland situation and take a leaf from Mayor Baker's policy. The friendship and good will of the thousands of small consumers who purchase current is something which the private companies need to cultivate. At the present time the average householder feels that he is being made to pay three or four times as much for the current as is paid by the large manufacturers and department stores, simply because he is helpless, whereas the large user will put in his own electric plant unless the central station gives him a low price.

A cut in the price of current to the householder may serve to stop agitation for municipal ownership before it begins, and the price reduction will be to a large extent made good to the company in the stimulus given to a larger use of electric light and especially of electric heating appliances.

Doubtless the figures we have presented above will be criticized. The financial interests at stake are so large that this is to be expected. But in order that such criticism shall be valid, it should be not merely general but should show wherein and by how much the assumptions on which the above figures rest are in error. If facts and figures exist which would modify the above calculation, by all means let them be brought forward; and if 1.96c. is too low or perchance too high for the cost of current from Cleveland's new municipal plant, let it be demonstrated how the estimate can be made more accurate.

It may be said, for example, that a municipal plant will be free from the city, state and federal taxation which is laid upon a private company and that due allowance should be made for this in computing the operating cost of a municipal plant. Such a criticism is entirely valid. We have not included it in the above figures for lack of data as to the proper amount to allow.

It may be said also that the low figures of cost which we have computed above will not be attained until customers are obtained sufficient to give the station an economic load. While the low rates offered are sure to attract all the customers that can be carried, some time will be necessary, of course, to extend the distribution system and reach them.

Of course, the new municipal electric plant can only serve a small part of Cleveland's great area and 700,000 population. The Cleveland Electric Illuminating Co., with its 100,000-hp. station, and its distribution system covering nearly the entire city is doubtless in the field to stay. For a good while to come it will probably prefer to relinquish customers to its municipal competitor rather than lower all its rates to the level set by the latter. It has, however, already met the situation in part by a large reduction in its rate, which it is claimed to be equivalent to a reduction of $800,000 per year in the payments for electric current in Cleveland.

Admittedly, the situation of the companies operating electric stations when faced with such business-like municipal competition as Cleveland has undertaken is a difficult one. Besides the burden of taxation which we have referred to, the companies in most instances have put far more money into their plants than would be required to replace them with plants as good or better at the present day and their interest charges on capital are 2 to 3% higher than a city has to pay.

In the long run, however, replacement value and not the amount of money invested in the past must be the measure of safe capitalization. The rule which applies under free competition must be made to apply to public utilities also. If the price of the machinery equipment for an electric station is cut in two, then the capital ought to be reduced in proportion, even though the old steam engines and slow-speed generators and small-capacity boilers may have actually cost all they are capitalized for. If alternating-current distribution makes an old direct-current system obsolete, then its cost should be written off to profit and loss. Any concern which carries dead capital on its books at its original cost, or at any more than its true present value, is in a weak position whenever a strong new competitor appears.

It is this situation, in fact, which gives the greatest excuse for municipal ownership and operation of certain public utilities at the present time.

The general principle is unquestionably sound that all publi utilities should be monopolies. Competition has been tried in water-supply, gas supply, street railways, telephones, and electric-lighting plants and has been proven in the long run to be a public injury instead of a public benefit. Economists and engineers are generally agreed that regulation of public utilities by public authorities rather than competition is the way out.

But it is not to be expected that a State public-utilities commission will compel a company to reduce its rates below the point necessary to yield a fair return on money actually invested; nor would the courts be likely to support such a forced reduction. If, however, a city like Cleveland can supply its citizens with electric current produced at lowest cost from an up to date plant there is no need of interference by commissions or courts.

And in conclusion, we should not by any means be understood as claiming that what Cleveland is doing in this field can be done by any other city anywhere. For one thing, Cleveland's advantages of cheap coal and abundant condensing water are great aids in reducing cost; but what is far more important is the success the city has attained in having its municipal enterprises carried out with a very fair degree of efficiency and honesty.

There will doubtless be other cities to follow Cleveland's lead in this experiment; but unless they are able to secure honest and efficient administration by competent engineers, and that not merely as a spasmodic effort at municipal house cleaning but as a permanent condition of city government—unless a city is able to fulfil this condition, experiments in municipal electric lighting will be apt to prove disastrous to the taxpayers.

Were it not for prevailing conditions in municipal government throughout the country, the electric-lighting companies would doubtless be even more concerned than they are over Cleveland's municipal electric plant.

Letters to the Editor

The SO_3 Content of Portland Cement

Sir—Prof. A. Baykoff, President of the Commission of the International Association for Testing Materials for the Study of the Influence of the Amount of SO_3 in Portland Cement, has communicated with the undersigned, who represent the American Society for Testing Materials on the Commission, in a letter which reads in part as follows:

As has been indicated in the report of the Association of German Portland Cement Manufacturers, various countries decide the question of the maximum amount of SO_3 in portland cement in a different way. Some make no difference between portland cement for fresh water and for sea water, others prescribe different limits according as the cement is to be used in fresh water or sea water.

Based upon these views, the VI Congress of the International Association for Testing Materials in New York adopted the following resolution:

> The Congress recommends generally that the conditions for accepting portland cement for all uses be fixed uniformly at a maximum amount of SO_3, that is to say, at 2.5%.

Thus the question proposed for the consideration of our Commission divides itself into two, which can be formulated as follows:

(1) Is it necessary to fix two different normals for the maximum admissible amount of SO_3 in portland cement according as the cement is designed for use in fresh water or in sea water?

(2) What should be the admissible maximum amount of SO_3 in portland cement under conditions conforming to the decision of the first question? Will it be necessary to use one or two normal figures?

As the solution of these questions can only be made after a sufficient quantity of exact data are available, it seems to me to be necessary, first of all, to collect a sufficient number of such data. With this object and independent of the researches which produce them or which are going to produce them, it will be useful to collect and discuss the greatest possible number of researches and the work devoted to the question of the influence of SO_3 on portland cement.

It seems to us that this matter should be put before the producers and users of portland cement in the United States so that such proposals in regard to the work to be done, and any data that may be available may be sent us for transmission to the President of the Commission. With this object in view, we are asking you to bring it to the attention of such persons through the columns of your journal. Communications are requested from all who are interested in the matter.

JOHN B. LOBER,
CLIFFORD RICHARDSON.

Woolworth Bldg., New York City, July 21, 1914.

Air-Valves and the Collapse of the Antelope Valley Siphon

Sir—In the excellent article on "Air Valves on Water-Supply Mains," by Clemens Herschel, in your issue of June 11, the writer notes the statement that the two ends of the Antelope Valley Siphon on the Los Angeles Aqueduct, which collapsed Feb. 18-20, 1914, were open. [See Eng. News, May 14, 1914, for account of collapse.—Ed.] The fact is that this siphon did not have its ends open, but continued at each end into a closed gravity conduit, formed by excavation into the ground, having sides and bottom lined with cement concrete and the top covered with a reinforced-concrete slab.

It is therefore impossible to conclude that the Antelope Valley siphon collapsed from negative water pressure, and not from the effect of a partial vacuum.

The writer has frequently observed phenomena of negative presure in water pipes, as stated by Mr. Herschel, and, under certain conditions, where the factor of safety is low, as in this case of the Antelope Valley siphon, distortion of the pipe shell might occur from such negative pressure. It is extremely doubtful, however, if not entirely impossible, for one to account for such a complete collapse as that occurring on the Antelope Valley siphon without the formation of a decided vacuum inside of the pipe.

That the middle portion of the pipe remained in shape is not a satisfactory explanation in this case, because air would rush in through the lower end of the pipe, where the rapid efflux lowered the water, so it did not occupy the entire cross-section in the pipe.

F. C. FINKLE.

I. W. Hellman Bldg., Los Angeles, Calif., June 17, 1914.

Sir—The article in your issue of June 11, 1914, "Air Valves on Water-Supply Mains," by Clemens Herschel, in its reference to the Antelope Valley Siphon, Los Angeles Aqueduct, brings out a very interesting point: that of "negative pressure while the pipe was still full of water."

The ordinary gage used on pipe lines does not show the true internal pressure tending to distend the pipe, but a pressure which is lower by 14.7 lb., due to the fact that the gage is itself subject to an external pressure to that extent. The true zero internal pressure is 14.7 lb. below the zero of the gage, and in changing from a high pressure to the true zero the conditions, when passing the zero of the gage, will be the same as at any other point in the range of movement. Assuming an air-tight pipe, the action will be the same below the zero of the gage as above it. There will be no parting of the water column, or pipe walls and water, until the true zero is reached. It is assumed in this discussion that the water is free of air and other substances tending to change its condition.

The fact that the pipe becomes subject to a collapsing pressure at a certain point in this pressure drop is due to the counterbalancing of the pressures at this point, and has no other relation to the change within. It is therefore clear that, in the absence of air in the pipe, it is possible to have negative gage pressure to an extent of atmospheric pressure, 14.7 lb. per sq.in., without a parting of the water column, or a separation of the pipe walls and the water.

To what extent a pipe will permit a lower pressure within than without will depend upon its resistance to collapse. Should it be unable to withstand an excess ex-

ternal pressure of 14.7 lb., it will be necessary to prevent the internal pressure dropping to the true zero. The surest way to do this is to provide for the admission of air to partly counteract the external pressure, and *to do this wherever the internal pressure tends to go below the zero of the gage.*

It is, on first consideration, astonishing to find what a slight change in flow conditions is required to produce these low pressures. To illustrate, consider a pipe line on an incline of the same grade throughout, filled with water and having a nozzle at the lower end. Let the pipe be 5 ft. in diameter, $\frac{1}{4}$ in. thick and under a head of 200 ft. at the lower end. Let the nozzle be of such size that it will produce a flow of 5 ft. per sec. in the pipe.

Reference to the formulas in the article, "The Calculation of Water-Hammer Pressures," in Engineering News, Dec. 4, 1913, will show that in such a pipe a ram pressure of 34 lb. follows a check in flow of 1 ft. per sec. It is equally true that a sudden increase in flow is accompanied by a fall in pressure of 34 lb. This depends upon the same law which controls the ram, and is nothing more or less than the action of gravity upon a compressible fluid in an elastic pipe. These effects have been too thoroughly demonstrated by theory and experiment to be open to doubt.

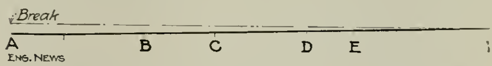
Suppose the nozzle to blow off, leaving a full pipe opening, and consider what will take place. Instantly the pressure of 87 lb. at the end of the pipe disappears, releasing the compressed water and permitting the pipe to contract, which two effects produce an additional flow of 2.54 ft. per sec. The pressure at the pipe end has fallen to atmospheric, which means that there is still an internal pressure of 14.7 lb. at that point. A wave of pressure drop, amounting to 87 lb., starts to pass up the pipe with a velocity of 2540 ft. per sec., but at a distance depending upon the inclination, a point is reached where 87 subtracted from the previously existing pressure reduces the internal pressure to the true zero. At this point, located about 34 ft. higher than the end, the water and pipe walls lose their power to furnish the required flow, and separation of the pipe walls and water takes place. It is seen that the pipe is subject to a superior external pressure varying from zero at the end to 14.7 lb. at the point mentioned.

Should the pipe be not sufficiently rigid to withstand this external pressure it will collapse and thus furnish the required flow with a less pressure drop. It is clear that the admission of air would produce the same result, in this respect, as the collapse, inasmuch as it would permit a partial evacuation of this part of the pipe to supply the required amount of water. Should no air be admitted and the pipe be strong enough to preserve its shape, a parting of the water from the pipe walls would result at the point where the true zero pressure was obtained, but not otherwise. The low-pressure wave will pass up the pipe, collapsing those portions of the line not sufficiently rigid to withstand it.

In this case an additional flow of 2.54 ft. per sec. (about 50%), brought about in the manner described, is sufficient to cause damage to a weak pipe line not provided with air valves in the proper place to care for such an emergency. This effect commences instantaneously and proceeds up the line with a velocity of 2540 ft. per sec. until the true internal pressure drops enough to permit the collapsing of the pipe by the external pressure or until the true zero is reached and separation takes place. In a uniform pipe this would probably take place between the upper wall and the water and not in the water itself. In lines consisting of pipes of varying size and thickness the conditions become very complicated, but, as a rule, it is possible to follow the effects until a collapsing pressure is found.

The point to be clearly understood is that the damage is done before any effect is felt at the upper end, and that prevention is to be found in the provision of adequate air valves along the line, even where the pipe will resist collapse. With the admission of sufficient air the pipe will flow partly full and the water will travel at a velocity dependent upon inclination and friction.

Referring to the Antelope Valley inverted siphon, the accompanying illustration shows the down-flow leg to the break and the table gives certain data pertaining thereto. Some of the figures are approximate only as they were scaled from a published diagram of small size. All pipe is 10 ft. in diameter.



Down-Flow Leg of Antelope Valley Siphon

Section	Length of pipe, ft.	Thickness of pipe, in.	Velocity of wave, ft. per sec.	Pressure change for 1 ft., lb.	Time of wave, sec.	Pressure at upper end, lb.
A B	2350	$\frac{3}{8}$	2300	31	1.02	78
B C	1415	$\frac{5}{16}$	2150	29	0.66	65
C D	1805	$\frac{1}{4}$	1965	26.5	0.92	39
D E	891	$\frac{1}{4}$	1965	26.5	0.45	33
E F	2736	9	2970	40	0.92	0

With such a break at the low point that free flow was permitted, the pressure at the end fell instantaneously to atmospheric, leaving an internal pressure of 14.7 lb., with no tendency to collapse. As the pressure fall was 87 lb. and 31 are required to give an additional flow of 1 ft. per sec., there was instantaneously added to the existing velocity a flow of 2.8 ft. per sec., calling for 220 cu.ft. per sec. This quantity would be provided by the pipe above the break to the limit of its capacity, which would be reached when the true internal pressure reached zero. As the pressure at *B* was 78 lb. per sq.in., there would have been, on the above assumption of free flow, a collapsing pressure of 9 lb. At *B*, where the wall thickness changes to $\frac{5}{16}$ in. and where a pressure fall of 29 lb. will increase the flow 1 ft. per sec., the required fall will be 81 lb., indicating a vacuum of 3 lb. In the $\frac{3}{8}$-in. pipe the true internal pressure will be 5.7 lb. and in the $\frac{5}{16}$-in., 11.7 lb. There would be an equalization of these pressures, raising the former and lowering the latter.

According to a table recently published by Enger and Seely, the $\frac{3}{8}$-in. pipe would partly collapse under such conditions, and the fact that it did not would indicate either that it was well supported, or, what is more likely, that there was not an entirely free flow permitted. To what extent the above conditions prevailed it is impossible to say, but it is evident that dangerously low pressures were promptly reached, and that had the lower sections been of sufficient strength to resist them, the usual lighter upper sections would have been damaged.

It is probable that the collapse started at the lower end and was completed during the rapid passage of the first wave of subnormal pressure; that air was supplied wher

the water reached the top, and that thereafter the pipe can partly fall until it was emptied.

In this particular case, judging from the published accounts, there was absolutely no reason to anticipate such extraordinary flood conditions, and therefore no reason to provide for them. Economy limits the engineer to reasonable safety provisions, and loss from unusual manifestations of nature must be accepted as part of the penalty we pay for living. Such a risk should be insurable for the same reason that we provide against fire loss and life hazard.

As the upper ends of this pipe were open to the air and as there were no summits along the line, it is evident that the dependence which has been placed on air valves, located at the summits, is not sufficient protection against damage following extensive rupture at any point on the line. *The entire line must be provided, at intervals, with valves of sufficient size to admit enough air to prevent the collapsing pressure reaching the limit fixed by the rigidity of the pipe,* and this air must be admitted during the time required for the passage of the wave of subnormal pressure from the break to the top.

S. L. BERRY.

417 Rialto Bldg., San Francisco, Calif.,
June 21, 1914.

[It seems to us that emphasis should be placed on a sentence in the last paragraph of the above letter which we have taken the liberty of italicizing. We do not believe that any computation can determine fully the particular points at which "negative pressure," which is really only another name for partial vacuum, may be developed under certain circumstances.

For example, a long level section of pipe may be flowing full at high velocity under considerable pressure. If a break occurs on this section, the pressure will be at once relieved, and at some point beyond the break, the water will flow backward toward the break while the water beyond this point will continue flowing, impelled by the inertia of the whole moving column of water in the pipe below.—ED.]

Making Cement Joints in Sewer Pipe

Sir: An interesting article, "Cement Joints for Sewer Pipe at Edmonton," appeared in your issue of July 9. The relative merits of certain details of procedure, under different specifications for pipe laying are discussed, and those which the author, J. M. Bogg, has found the most satisfactory are incorporated in his quotation from the Edmonton specifications.

I have had some experience with cement mortar joints made in three different ways: (1) where a gasket was not used; (2) where a gasket was inserted against the shoulder of the bell in the usual way; (3) where the gasket in the finished joint was at the entrance to the bell all the way round, calked flush with, or a little inside the outside edge of the bell. In all cases, the bottom third of the bell was lined with mortar before inserting the pipe. When no gasket was used, pipe 15 in. and over was centered by two small wooden chips. These chips were also used with the gasket in laying the larger sizes, 18 in. and over. Ordinarily, no difficulty was experienced in centering the 8-in. and 10-in. pipe without chips, whether a gasket was used or not. In every case the joints were pointed from the inside for all pipe 15 in. and over. In methods (1) and (2) the joints were protected with a burlap or cheesecloth band for pipe 18 in. and over.

So far as my experience goes, I am of the opinion (1) that the lower part of the bell should be filled before the spigot of the succeeding pipe is entered, and with more mortar than is needed in that part of the joint; for safety the mortar should appear on the inside; (2) that it is important to use a gasket, not only to assist in centering the pipe, but I believe that the clogging, or silting up of a gasket calked tightly into the bell, is a considerable factor in preventing leakage in either direction through the joint, where the cement mortar itself is defective; (3) that while no doubt it can be dispensed with, it is safer to use chips to prevent the larger pipes settling at the spigot end; (4) that while it is proper to give the joint a finished appearance by a moderate bevel, the so called generous bevel is, if anything, worse than useless with the larger sizes, as it tends to sag away from the sides of the pipe; (5) that with the larger sizes, the joint should be supported by a strap of burlap, etc., unless a gasket is inserted at the face of the bell after the joint has been filled up the sides and over the crown.

Moreover, the third method of joint making has appeared to insure the tightest work so far as I have seen it used. This joint is made by lining the bottom third of the bell in the usual way, covering the gasket which is placed along the outside edge of the bell. The gasket is long enough to encircle the pipe, and the two end sections are brought out of the bell after passing clear of the mortar in the bottom. The spigot end of the pipe is then entered with its crown guided against the bell, worked down to center at both ends and bedded. After the joint has been completely filled with mortar, the free end sections of the gasket are calked into the bell working from the bottom toward the crown. The gasket is driven flush with, or a little within, the face of the bell, the bevel applied, the joint pointed on the inside where accessible, and the surplus mortar cleaned out. There is not very much mortar driven through, particularly with the smaller pipe.

This feature of the mortar forcing through is occasionally objectionable in a way that is hard to avoid. The 12-in. pipe and under cannot be pointed from the inside, and if as sometimes happens, the plane of the spigot end is not perpendicular to the axis of the pipe, there may be a considerable space at the crown of the joint between the spigot end and the shoulder of the bell; and the mortar filling this space sometimes drops to the invert after the pipe laying has proceeded some distance in advance.

When laying 12-in. pipe, this feature has to be watched; it rarely happens with 8-in. pipe, or with the larger sizes where the joints have been pointed from the inside. With the joint made in this way the mortar is firmly held in the bell, and even if the bevel does sag, it cannot carry the mortar out of the bell with it.

I have not found the chips objectionable in the way Mr. Bogg suggests; perhaps more mortar was placed in the bottom of the bell; at any rate the chips did not keep the pipe off the mortar; they were practically buried in it near its upper edges. The chips were placed in this position, so that they could be easily moved a little higher, or lower, when [illegible] required; moreover, with the

chips in this position, any inequalities in either the pipe or the chips do not raise or lower the spigot end so much as if the chips were placed lower down, opposite a diameter approaching the vertical. However, there is no doubt that with the chips omitted, the gasket will generally be fitted tighter in the bottom, and that is a desirable feature.

The consistency of the mortar is an important matter, and not at all easily controlled. The tendency is to have the mortar too soft, as it is easier for the pipe layer to handle. Unless quite stiff initially, the mortar which has been hurriedly mixed, becomes sloppy on further handling, and cannot be easily compacted or retained in the bell. The man who mixes the mortar often has too many other things to look after. The mortar should be mixed in very small batches, and kept thoroughly stirred some time before being used. This permits the mixture to absorb more water, and the proper consistency can be better gaged by the mortar man as further handling does not affect it; moreover, the mortar appears to be tougher, and works smoother.

Mr. Begg has adopted a good specification at Edmonton. Clause (e) which specifies that no joint is to be completed until at least two joints have been bedded and graded in advance is to be particularly recommended. In reading his well presented article, I had hoped to find the detailed description of the work extended to include the method or the procedure followed in bedding the pipe. It is in connection with this, that the most serious difficulties arise in laying sewer pipe. It requires considerable skill and patience to bed a pipe firmly, and at the same time have it lying true to grade and alignment. It is true, that once the pipe is in the right position, it can be held and supported by tamping proper filling around it with a thin-bladed tool. In this operation lies the greatest risk of lifting the spigot end slightly from the mortar in the bottom of the bell.

It has been the writer's practice to defer tamping immediately around the joint until after the mortar has set up; but in bright, hot weather, at least, the joints were covered with loose earth. Before back-filling the trench the following day, some of this filling was removed, before the tamping was completed. Possibly this was not a good system; care certainly had to be taken to maintain the compacted filling at the same level on both sides of the pipe, so as to avoid jarring it slightly off the line; it is surprising how easily this can be done with even a very light tamping iron.

W. S. Lea.

New Birks Bldg., Montreal, Can., July 19, 1914.

Sir—The editorial in the July 16 issue of Engineering News, relating to sewer-pipe joints, has been read with much interest by me as also the preceding week's article by Mr. Begg.

I am strongly in favor of incasing small-sized sewer mains and laterals in concrete as suggested by you, not only on account of its protection against seepage but also on account of safeguarding the pipes against almost certain breakage caused by workmen driving a pick though the pipe when a new ditch happens to cross the line of the old sewer. A covering of concrete is an immediate and positive warning of an existing sewer pipe and the workmen will naturally stop and find out what it is before digging it out.

My reason for answering this editorial is that I strongly object to the method suggested of covering the pipe with concrete as per the sketch on p. 147 of your issue of July 16, without at the same time calking the joint with jute and filling with cement which should be tied up tightly with a strip of muslin. The sewers under discussion would in general be from six to ten feet below ground and especially after a rain of any duration would be under from two to five feet of ground-water head and the covering of concrete could not possibly keep out the water. It is generally agreed that it is easy to keep water in concrete but a problem to keep it out.

It would seem, however, that the combination of all the methods suggested to date would make a good general working method of laying sewer pipes and insuring the maximum efficiency of the joints; namely, according to the size of the city, have one man definitely charged with the responsibility of having water-tight joints in his section, lay all pipes according to the very clear specifications suggested by Mr. Begg and finally to incase all mains and laterals up to perhaps 15 in. in concrete for protection from seepage and from tree roots.

A Warning to Railway Construction Engineers in Pennsylvania

Sir—Referring to the letter of M. E. R. in the July 9, 1914, issue of Engineering News, relative to a warning to railway construction engineers working for English companies, which concludes with "It would be wise for men who have employment contracts under English law to insist on having their salaries paid at the end of the month," M. E. R. does not have to go to England for this kind of law. Certain employees of insolvent companies will find that the State of Pennsylvania has a similar law.

Some years ago, the undersigned was chief engineer of a Pennsylvania state railroad which failed and went into the hands of the sheriff for adjudication. Upon trying to collect his claim he found that the only preferred creditors were clerks, miners, mechanics and laborers; so although he had "labored" hard during his engagement, he had to be satisfied with a very small percentage of his claim. Under this law there is even a distinction between a clerk and a bookkeeper.

So long as engineering societies are nothing but literary clubs, no redress need to be looked for.

Civil Engineer.

Buffalo, N. Y., July 10, 1914.

Portland Cement Manufacture in the Philippines is one of the possibilities of the future. The "Philippine Journal of Science" for February contains an article by Augustus T. West and Alvin J. Cox describing tests of raw materials available in the Philippines for portland-cement manufacture which showed excellent results. All the cement now used in the Philippines is imported. The consumption in the fiscal year 1913 was just short of 400,000 bbl. Cement from the United States is imported into the Philippines free of duty but the transportation cost is so great that American cements do not compete in the Philippine market. The selling price of cement in the Philippines on large contracts is stated to have varied from \$2.18 in 1907 to \$3.34 in 1912.

Sewer Explosions and their Prevention*

By Leonard Metcalf and Harrison P. Eddy†

SYNOPSIS—This article, composed of extracts from a forthcoming book on "Modern Sewerage Practice," gives in detail the precautions to be observed by sewer workers to avoid the danger of explosions. The nature of sewer explosions is gone into and the Washington City ordinance for preventing explosive mixtures in sewers are quoted. Dangers of asphyxiation are also described and precautionary measures outlined.

When a sewer is to be entered, or a lighted lamp or candle is to be lowered into it, great care should be exercised to avoid danger of explosion. Men accustomed to this work will quickly perceive the presence of illuminating gas or gasoline vapor, by the odor. This is the safest method of testing the air, but the observer should be careful to note whether the air is entering or emerging from the manhole, otherwise he is likely to mistake the absence of odor for the absence of gas in the sewer. If it is necessary to enter the manhole to determine the presence of gas, this should be done without a light, unless it be an electric lamp, and the man entering should wear a life belt with a line leading to his helpers at the top of the manhole. Although seldom done, it is always wise to open several manholes in the sewer to be entered some little time before the entrance is to be made, in order to provide a change of air within the sewer.

An inspection in, or very close to a manhole, should never be attempted by one man alone; the inspector should have at least one helper both for his protection and that of the public, and usually more than one. The helper should remain standing at the top of the manhole to warn approaching persons of the opening. Where the inspector is to go from manhole to manhole through the sewer a second helper should precede him to the manhole below that at which he enters. When the inspector has reached the second manhole, the second helper signals the first one at the first manhole, who replaces the lid and passes on to the third manhole, awaiting the arrival of the inspector at that point. Three men constitute the minimum safe size of gang for such inspection, and preferably two men should go together through the sewer.

Danger of Explosions

Many explosions have occurred in sewers due to explosive mixtures of illuminating gas, gasoline vapor and possibly other gases. Illuminating gas leaking from a defective gas main may find its way through the ground and into a sewer in sufficient quantity to cause an explosive mixture. Most superintendents of sewers have had experiences of this kind, although relatively few instances have resulted in explosions. It is not always easy to find the source of such gas, as it may travel a considerable distance from the point where it enters the sewer to the place where it is detected.

During recent years, trouble has frequently resulted from the discharge of gasoline into sewers, largely from automobile garages. Gasoline vapor is considerably heavier than air and therefore is not always readily distinguished by its odor when the observation is made from the top of the manhole. This new source of danger has necessitated ordinances preventing the discharge of gasoline into sewers and approving lighting appliances for the use of inspectors and laborers while working within the sewers.

An explosive mixture may result from the decomposition of the organic matter in the deposits. By such decomposition, marsh gas, or methane, may be produced in considerable quantities, and if there is not an adequate circulation of air to provide ventilation, it is conceivable that the proportion of this gas to the oxygen in the air in the sewer may be sufficient to provide an explosive mixture.

On Nov. 25, 1913, what was probably the most disastrous sewer explosion on record up to that time occurred in Pittsburgh, Penn. A detailed account of this accident was printed in Engineering News, Jan. 1, 1914. A series of spectacular explosions occurred in sewers in New York City, on Oct. 7, 1909, which was described by A. A. Breneman in Engineering News, Dec. 2, 1909, p. 608. The conclusion seemed to be that these explosions were due to gasoline vapor.

H. J. Kellogg, Assistant City Engineer, New Haven, Conn., carried on investigations for about a year to determine causes of, and to find means for preventing, explosions in sewers. He reported some of the results of these investigations in a paper read before the Connecticut Society of Civil Engineers, Feb. 10, 1914, from which the following notes and comments are taken:

> In 1886 there was an explosion in a New Haven sewer 60 in. in diameter. The arch was thrown completely off for about 100 ft. No one knows what combustible wrought the destruction, nor how it was ignited. No one was injured. . . . About 1891 a 3-ft. circular brick sewer was being flushed by four men when an explosion occurred. The men escaped with difficulty, two of them being disabled for six months or more. The cause of the explosion appears to have been illuminating gas ignited by candles which the men carried. . . . In 1913 a 12-ft. egg-shaped New Haven brick sewer was being cleaned when an explosion occurred, burning the men about their hands and faces. The cause of this explosion does not appear to have been definitely determined, although a slight odor of gasoline was noticed before the men entered the sewer. If gasoline was the cause of the explosion, it probably came from a manufacturing plant, the drain from which entered the sewer close to the point at which the explosion occurred. Very small quantities of gasoline are used at this plant.

At Philadelphia, an explosion in which several men were injured was attributed to gasoline vapor. Mr. Kellogg quoted from a letter from George S. Webster, Chief Engineer, Bureau of Surveys, as follows:

> A disastrous result was noticed upon opening a sewer manhole, and a blazing paper thrown in resulted in a column of flame about 40 ft. in height, due to gasoline from a nearby factory.

*Abstracted by the kind permission of the authors and publishers from a forthcoming book on "Modern Sewerage Practice," by Leonard Metcalf and Harrison P. Eddy. McGraw-Hill Book Co., publishers. The extract is from Chapter IX, "Operation and Maintenance of Sewerage Systems."

†Consulting Engineers, Boston, Mass.

Two men were killed in a Philadelphia sewer explosion about 1912. The cause is said to have been illuminating gas from a leaky main which ran parallel to the sewer. At a later date a man was burned by an explosion resulting from gasoline discharged from a dry-cleaning shop.

Explosions in sewers were reported from Providence, R. I., Buffalo, N. Y., Washington, D. C., Fall River, Mass., Detroit, Mich., Brooklyn, N. Y., Cleveland Ohio, Worcester, Mass., St. Paul, Minn., Kansas City, Mo., Duluth, Minn., Los Angeles, Calif., Savannah, Ga., Baltimore, Md., Hartford, Conn., New Haven, Conn., Pittsburgh, Penn., San Francisco, Calif., Louisville, Ky., and Charlestown, S. C. The cause of explosion in a majority of these places was reported as illuminating gas.

George H. Norton, Deputy Engineer Commissioner, Buffalo, N. Y., described a new gas found in sewers as follows:

It may be interesting to know that for three years past, at periods following thawing weather, after frost and heavy snow, we have had serious complaint from gas odor in some of our sewers. This has been traced and found to be due to the use by the railroads of what is called a hydro-carbon oil, which is used by them to prevent freezing of their switches and interlocking plants in their passenger station yards, and at other congested points. An examination was made by the city chemist, and he reported that at low temperatures this oil will crystallize, that such crystals are soluble in water, and for this reason he thinks that the odor or gases have passed the ordinary vent sewer trap. The gases arising from this oil are apparently highly explosive and would readily be the cause of a serious explosion. This oil is a byproduct from the Pintsch gas used for car lighting.

Roscoe M. Clark, City Engineer of Hartford, Conn., gave the following information:

I have no recollection of any explosions in the sewers previous to 1913. In 1913 we had two serious explosions in the Park River intercepter. The first, occurring in January, lifted one manhole head and threw several covers in the air, and also shattered windows in adjoining houses. The second occurred in May, when the East Side Pumping Station and its connection with the Park River intercepting sewer were in the process of construction. The most damage was done to the station and adjoining houses. Both of the explosions took place in the vicinity of the works of the Hartford City Gas Light Co. Suits brought by property owners and the contractor for the pumping station are now pending in court.

Robert Adamson, Fire Commissioner of the Borough of Manhattan, New York City, reported that there were eleven sewer explosions between June 5, 1912, and the date of Mr. Kellogg's inquiry, probably about a year later. He stated that the probable causes of explosions in New York are gasoline, illuminating gas, and calcium carbide. He stated further that prior to the regulation requiring the installation of oil separators in garages, the majority of sewer explosions was limited to what is known as the "garage zone." Since their installation, the number of explosions has been greatly reduced. The following quotation is from Mr. Adamson's letter:

The illuminating gas enters the sewer from ruptured, corroded or broken gas mains, or from leaky joints, and when mixed in the proper proportions with air forms an explosive mixture. Calcium carbide, which is used in garages for generating lights, may be thrown into the sewer, and when in contact with water generates acetylene gas, which is an intense explosive and is further auto-combustible, so that in many instances it may be lighted by its own heat generated in evolving the acetylene.

The vapors of gasoline and illuminating gas require an open flame to ignite them, but whether this occurs in sewers it is impossible to tell. In vaults and in conduits the igniting spark is furnished in a number of cases by electrical apparatus, such as switchboards, sump pumps, short-circuiting, etc.

Some relation exists between sewer explosions and flooding of the sewers, and further, when the sewers become tide-bound these explosions are more frequent, such as following an unusual shower of heavy rain or a fall of snow or thawing of ice. This causes a condensation of the gases within the sewer.

There are no causualties on record resulting from these explosions, but considerable damage to property often occurs.

In relation to places where oil is stored, the oil separator is the only method at present under the regulations of preventing volatile inflammable oil from discharging into the sewer.

Mr. Kellogg stated:

That one volume of gasoline oil produces 141 equal volumes of gas or vapor, as figured by the city's chemist, who gave as the computed best mixture for complete combustion: 1 part of gas to 62½ parts of air. In gas engines, especially in automobile driving, an excess of air is said to give better practical results. The following figures lead up to a knowledge of the amount of gas likely to be in a sewer from a given amount of oil: 1 gal. gasoline gives 141 gal. of gas; 141 gal. gas equals about 18.8 cu.ft. of gas; 18.8 cu.ft. of gas with 1175 cu.ft. of air gives the best explosive mixture.

There is a broad variation in the proportions of this gas and air that will form combustible mixtures. Now, allowing 8 cu.ft. as the available space for 1 lin.ft. of a 42-in. sewer, in New Haven, 1 gal. of gasoline could have furnished a prime mixture for about 150 lin. ft. of that sewer. A leaner but still dangerous mixture might more than double the danger zone. Although the rate of flow in the sewer, the time it would take to vaporize the oil, the draft in the sewer and perhaps other factors complicate the problem, the above figures show that a comparatively small quantity of gasoline is capable of making trouble.

Mr. Kellogg also stated that about one part of illuminating gas to about seven parts of air is computed to be the best mixture for complete explosive combustion.

The following ordinance from Washington, D. C., appears to provide as ample protection as is possible by law:

Sec. 18. No persons shall make or maintain any connection with any public sewer or appurtenance thereof whereby there may be conveyed into the same any hot, suffocating, corrosive, inflammable or explosive liquid, gas, vapor, substance or material of any kind; and no persons shall cause to enter or flow into any public sewer or appurtenance thereof any hot, corrosive, suffocating, inflammable or explosive liquid, gas, vapor, substance or material of any kind; provided, that the provision of this paragraph shall not apply to water from ordinary hot-water boilers of residences.

On Jan. 3, 1912, the Municipal Explosives Commission of New York adopted a code of regulations, some of which bear directly upon the admission of inflammable oils to the public sewers.*

The "Paragon" gasoline and oil separator is an apparatus which has been put upon the market by the Ansonia Manufacturing Co., of New York, to meet the regulations of the New York City ordinances. In it, by taking advantage of the difference in specific gravity, the oil and gasoline are allowed to overflow into an oil chamber while the water passes through the trap and out into the sewer. From time to time, as oil and gasoline accumulate in the chamber, they are drawn off or pumped out.

The occasional presence of illuminating gas in sewers has been a matter of common knowledge for a great many years. It does not seem that there is at present any tendency toward an increase of this sort of trouble, and so far as the authors know, there is no means of preventing its occasional occurrence. It is usually discovered and reported before an explosion occurs. When reported, every effort should be made to immediately ventilate the sewer in which it is found and to locate the leaks in the main which is permitting the gas to escape.

* Printed in "Engineering News," July 2, 1914, p. 12.

The trouble arising from gasoline vapor in sewers appears to have increased greatly in the last few years with the increased number of gasoline engines and automobiles in use. Something toward decreasing the danger can be accomplished by means of oil-separating traps thoroughly well ventilated to prevent the escape of gasoline into sewers. This does not seem to have met with general application, however, and great care should be exercised by those entering sewers to avoid danger of explosions. One of the best means of accomplishing this is to prevent open flames in sewers by using the electric lantern.

An instructive discussion by D. B. Rushmore, of safety lamps and a new electric light for miners, appears in ENGINEERING NEWS, Aug. 15, 1912. The electric lamp, made by the General Electric Co., is a combination of the hand lantern and headlight, consisting of a miniature tungsten-lamp unit operated from a light storage-battery. The battery has a capacity of 5 amp.-hr., and is of sufficient size to operate a lamp from 12 to 14 hr.

When used as a headlight, the lamp is fastened to the miner's cap and connected by a flexible chord to the battery, which is flat, $6\frac{1}{2}$x$1\frac{5}{8}$x$1\frac{1}{8}$ in., weighing 3 lb. and is carried on a belt. When used as a hand lantern, the lamp socket is removed from the cap receptacle and inserted into the receptacle on the side of the battery, simply taking the place of the cable attaching plug.

OTHER SEWER DANGERS

Even though the danger of explosion is avoided, in exceptional cases gases may be present in sufficient quantities and of the proper kind to endanger the lives of the men working in the sewer. Illuminating gas, while most common, may usually be detected by its odor. If, however, there are some gas-works wastes in the sewage which impart odor to the air and yet are not dangerous, the men may gradually come upon a quantity of illuminating gas without noticing the difference in odor, and be overcome.

There is also danger from marsh gas formed in decomposing deposits and liberated in large quantities when these deposits are disturbed, as by being shoveled or walked upon. Hydrogen sulphide may also be formed under similar conditions, especially where the sewage contains sulphates, as from very hard water or sea water. An illustration of such conditions is furnished at the end of the Los Angeles, Calif., outfall.

Another illustration is afforded by the death of three experienced sewer workmen at New Bedford, Mass., on Apr. 10, 1914. A section of an intercepting sewer had been closed by a bulkhead in order that the portion below the bulkhead might be put in use while that above was being completed. The men entered the sewer at a manhole 400 ft. above the bulkhead. They adopted none of the precautions advised in this chapter. About 8 hr. later, their bodies were found by a searching party under conditions which indicated that they had probably worked their way well down toward the bulkhead, when they discovered the presence of gas. One of them escaped to within 100 ft. of the manhole and then fell over with his face in a little trickle of water on the invert, in which he was probably drowned. The others did not get nearer than 300 ft. to the manhole; their bodies were found against the wall of the sewer, the arm of one through that of the other in a way indicating that he was helping the latter when both collapsed.

The only practicable way in which to avoid danger of being overcome by such gases as may be found in sewers under exceptional circumstances appears to be to provide liberal ventilation before entering and while working in them. Care should also be exercised to provide young and vigorous men for such work, to see that there are sufficient men in the party to provide necessary assistance in case of need, and to require that life belts be used, when the men are in particular danger. For emergencies, the breathing apparatus used in mine-rescue work and for entering burning buildings may prove useful. Such apparatus is described in Miners' Circular 4, U. S. Bureau of Mines.

Effect of High-Pressure Steam Mains under Streets

Damage to streets, sewers and paving by the presence of high-pressure steam mains in the street having been proved by an extensive investigation, the Public Service Commission for the First District, New York, on July 23, ordered the New York Steam Co. to remove and replace its 58,986 ft. of steam mains of the brick-trench type with mains of the modern tile construction shown on the accompanying drawing, or by some other type equally good, to be approved by the Commission, within five years, at the rate of not less than 12,000 ft. per year, beginning Sept. 1, 1914.

The New York Steam Co. was formed back in 1880. It is said to be the only concern of its kind operating high-pressure steam lines for heating and power. Three steam-boiler plants are operated. One, known as station B, built about 1885, in the lower part of the city, has a rated boiler capacity of 15,800 hp. The second, station A, built in 1897, with a rated capacity of 11,700 hp., is at the foot of 59th., East River. The third is at about the same location and is called station J Addition. It was built in 1908 and has a rated capacity of 1800 hp.

Station B supplies steam at 95 lb. boiler pressure with 30 lb. pressure at the extreme end of the mains. The steam from this plant is used about equally for heat and power. The other two plants serve the uptown district with steam at 55 lb. boiler pressure with 10-lb. pressure at the end of the mains. The steam is used almost exclusively for heating. The temperature of the steam in the mains is over 300° F. In addition to these stations, the company owns three ice plants with a combined daily capacity of 195 tons. The total value of the property of the company is estimated at $7,168,000.

The chief engineer of the company stated that the cost of relaying a 10-in. (the average size) main was about $18 per foot, and that this cost was greater than that of laying new mains because of the necessity of maintaining service and of removing the old pipe. In the uptown district there were 685 customers, 173 of which were supplied through meters, the others were served at flat rates. In the downtown district, there were 456 customers, all supplied through steam meters. It was stated that the maximum price charged for steam is $2 per thousand pounds. The minimum rate is 45c.

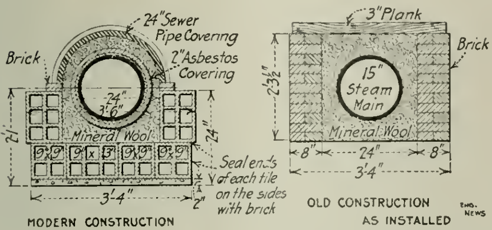
CONDITION AND EFFECT OF STEAM MAINS

The investigation revealed that it was a common occurrence to find the earth, for some feet outside the brick

walls of the steam mains, filled with steam which escaped when the earth was disturbed, and that the temperature of this earth ranged from 85 to 193° F. even in winter. One effect of these mains was to burn the leather washers in the water hydrants, and water discharged from some high-pressure hydrants was hot enough to give off steam. The unsatisfactory condition of the wood-block pavement in certain streets and their excessive cost of maintenance, can be attributed largely to the effect of the steam mains.

At street intersections, the waterproofing of the subway on lower Broadway was damaged by heat from the mains; the asphalt had practically disappeared, and the fabric was dried up and cracked. This effect is most important, because much of the new subway now under construction on lower Broadway is below high-water level, and waterproofing will, therefore, be necessary. This new line will encounter many steam mains between Chambers St. and Park Place, and elsewhere.

As for the effect of the steam mains on pavements, it was observed that on damp days such pavements were



PRESENT MAIN CONSTRUCTION OF N. Y. STEAM CO. AND NEW TYPE WHICH WILL REPLACE IT

dry, and the manholes in the street emitted steam, and that a light fall of snow would melt quickly.

In a certain sewer manhole back of Trinity Church, the temperature was 132° F., and in the sewer nearby was 180°. This temperature prevented men from working in the manholes. Another effect of this high temperature in sewer manholes was bad odors which issued from them. It was stated to be the consensus of opinion in the Department of Public Works, New York City, that the steam will loosen the cement in the joints of the sewer brickwall. In another manhole a 3-in. drip-pipe was discovered protruding through the wall and discharging into the sewer, steam at 210° F.

In the manholes of electric-cable subways, the temperature from the steam mains reached as high as 180° The effect of this temperature is not only to prohibit men from working in the manholes, but also to prevent the cables from working to full capacity.

It was stated that 60% of the steam pipes had screw flanges, which frequently leaked at the threaded connections. The chief engineer of the company said that welded flanges came in use on the system in 1901; and that about half of the mains in both districts had welded flanges and were laid in drained trenches. The number of feet of mains of modern tile construction in the downtown district is 3796, and in the uptown district 10,751, a total of 14,517 out of 73,553 ft., or less than 20%. The chief engineer of the company claimed that no leakage troubles were experienced where the trenches were drained and welded flanges used. His explanation of certain steam leaks which were proved to exist was that the trenches were not drained there, and that, although the pipes had welded flanges, they were the first of that kind so fitted, and that the flanges were made of wrought iron and had "porosity in them." The steam company claimed that much of the damage caused by leaks and radiation was because other subsurface structures have been located too close to the steam mains.

The report goes on to say that:

subsurface structures in many streets of New York are numerous, and space is limited. Each must be so constructed as not to injure the others, and that the record shows that no injury would have been caused had the steam mains been properly constructed. The steam company also says that much of the trouble is caused by leaks from water mains and house service piping, which is notoriously bad. But water pipes cannot be dispensed with, and the business of the steam company must adjust itself to conditions as they exist.

Mr. Goodrich [Consulting Engineer to the President of the Borough of Manhattan] testified that at Detroit, Mich., steam mains are placed in a tunnel which is from 15 to 35 ft. below the surface of the street, and that it would be feasible to construct such tunnels in New York.

The recent inquiry has been limited to the question of improvement in the distribution system of the steam company. No investigation has yet been made of the generating plants, or of other methods employed by the company in the conduct of its business.

New Locomotives for the Pennsylvania R.R. have been designed specially for use on the main line between Pittsburgh and Altoona, the purpose of the freight engines being to reduce double-heading to a minimum and to avoid breaking up trains at these points owing to the severe grades on this division. The clearance limits are restricted, and the weight per driving axle is limited to 65,000 lb. (with a 5% margin for scale variation), and the dynamic effect of the unbalanced reciprocating parts at 70 m.p.h. is limited to 30% of the weight on drivers. It was necessary to increase the power without exceeding the present clearances and to make the moving parts as light as possible while maintaining ample strength.

The running gear has been lightened by the use of heat-treated steel for driving axles, crankpins, piston rods, and connecting side rods, while the axle, pins and piston rods are hollow. The engines have the Walschaerts valve-gear, Schmidt superheaters, firebrick arches and screw reversing gear. The cabs are of steel, and much shorter than the ordinary design, this being made practicable by the use of the power reversing gear. The boilers and tenders are the same for both classes, and the boilers have the Belpaire firebox, 80x126 in.

The freight engines are of the 2: 8: 2 class, superseding a 2: 8: 0 class having cylinders 25x28 in. and a driving-wheel load of 220,000 lb., as against 27x30 in. and 262,000 lb. in the new engines. The tractive power is 57,850 lb., and 46,290 lb for the new and old engines respectively. The passenger engines are of the 4: 6: 2 class, taking the place of a 4: 4: 2 class having cylinders 23½x26 in. and a driving wheel load of 133,100 lb., as against 27x28 in. and 200,000 lb. for the new engines. The tractive power is 41,845 lb. for the new and 29,427 lb. for the old engines. The leading dimensions of the new engines are as follows

	Freight	Passenger
Class	2: 8: 2	4: 6: 2
Weight, total	330,000 lb.	305,000 lb
Weight on driver	262,000 lb.	200,000 lb
Wheelbase, driving	17 ft. ½ in	13 ft. 10 in
Wheelbase, engine	36 ft. 4½ in.	36 ft. 2 in.
Wheelbase, engine and tender	72 ft. 3 in	71 ft. 10 in
Cylinders (2)	27x30 in.	27x28 in.
Driving wheels	5 ft. 2 in.	6 ft. 8 in.
Boiler diameter	6 ft. 6¼ in.	6 ft. 6¼ in
Working pressure	205 lb	205 lb
Tubes length	19 ft	19 ft
Heating surface tubes	3747 sq.ft	3747 sq ft
Heating surface, total	4036 sq.ft	4036 sq ft
Superheating surface	1151 sq ft	1151 sq ft
Grate area	70 sq ft	70 sq ft
Rail to center of boiler	9 ft. 9 in.	10 ft. 1 in.
Water in tender	7000 gal	7000 gal
Coal in tender	25,000 lb	26,000 lb.

The Ohio River Bridge at Metropolis; Record-Breaking Simple-Truss Span

One of the most important of the many large bridges now projected and under construction is the new Ohio River bridge at Metropolis, Ill., the work for which has just been commenced and which will form part of a new railway route from northern and central points to the Gulf. The bridge will be a double-track structure, designed for unusually heavy loading and having a truss channel span 722 ft. 11 in. long between centers of piers. This span, being some 50 ft. longer than the main truss spans of the Municipal Bridge at St. Louis, will be by a large margin the longest simple span ever built.

The Metropolis Bridge will be built and owned jointly by the Chicago, Burlington & Quincy R.R. and the Nashville, Chattanooga & St. Louis R.R., and will form part of a new line between Metropolis, Ill., and Paducah, Ky., a distance of 15 miles. It is the development of a project initiated about 2½ years ago to establish a new and direct railway route between Chicago and Gulf ports (Engineering News, March 21 and May 2, 1912). This project was for a double-track bridge near Paducah to be built jointly by four roads (the Chicago, Burlington & Quincy, the Chicago & Eastern Illinois, the Illinois Central and the Louisville & Nashville). The bridge with its railway connections was to form the main part of a line between lines north of the Ohio and the New Orleans, Mobile & Chicago Ry., a new line owned by the 'Frisco and Louisville & Nashville railways. Financial and other troubles broke up the original project, but it is now to be carried out on practically identical lines.

The bridge proper will have a channel span of 723 ft., four truss spans of about 550 ft., with a 300-ft. shore span at the north end and a 250-ft. shore span at the south. This last is a deck span, while all the others are through spans with pin-connected trusses of the Petit type. The trusses of the through spans are spaced 37, 35 and 32 ft. c. to c. for the 720-ft., 551 ft. and 300-ft. spans respectively, while the maximum truss depths are respectively 110 ft., 82 ft. and 58 ft.

The north approach is a steel viaduct about 1600 ft. long, having 30-ft. tower spans and 75- to 90-ft. intermediate spans; at one point (where the line crosses a railway) the spans are carried by masonry piers instead of the steel towers. The south approach is similar, with alternating 30-ft. and 75-ft. spans, but having a length of only 600 ft. These approaches will have a concrete deck for ballasted track. The total length of bridge and approaches is about 5700 ft. The bridge is practically level, with ascending approach grades of 0.2% at the north and 0.3% at the south. The clear headway above high-water level is 53 ft., or 112 ft. at low water.

The foundations for the seven river piers will be sunk through a firm sand and gravel formation, pneumatic caissons being used; the maximum depth below low-water level is about 78 ft. The pedestals of the viaduct approaches will be supported on pile foundations, which will be built by the railway company.

A special feature of the bridge is the very heavy live-load assumed in the design, this being (for each track) two engines of Cooper's E-90 loading followed by a train load of 7500 lb. per lin.ft. This was adopted in view of the increasing weight of locomotives and trains, and to maintain uniform unit-stresses under these future heavy loads.

THE OHIO RIVER BRIDGE AT METROPOLIS.
(C. H. Cartlidge, Chief Engineer; Ralph

The bridge will be built by the Paducah & Illinois R.R. Co., a subsidiary of the Chicago, Burlington & Quincy R.R., and the Nashville, Chattanooga & St. Louis R.R. The Chief Engineer is C. H. Cartlidge (Bridge Engineer of the C., B. & Q. R.R.), and Ralph Modjeski is Consulting Engineer. The total cost will be about $3,500,000 for the bridge and approaches. The contract for the seven river piers was awarded in June to the Union Bridge & Construction Co., of Kansas City, Mo. Bids for the superstructure (the seven truss spans only) were received July 20, and the contract probably will be awarded in a few weeks. The bridge is to be completed in 1916.

Graphite Treatment for Boiler Scale

By L. W. Brooks*

Much has been heard in the last two years of the use of graphite in removing scale and sediment from steam boilers, and the writer has felt that this treatment should be of great interest to readers of Engineering News, comprising as they do a large number of water works engineers and general contractors.

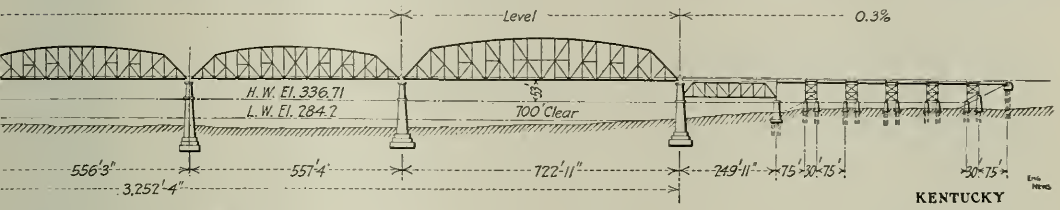
Many believe the scheme to be a new one but really it dates back 25 years. Active interest in preventing boiler scale continues for two reasons: (1) reduction of efficiency—a deposit of scale 1/16 in. thick increases the fuel burned by 5 to 15%; (2) decrease in safety of operation—for scale is so poor a conductor that the boiler metal may be overheated.

In most plants the firemen have their own favorite methods of attacking the scale problem. Some are partly

*461 York St., Jersey City, N. J.

successful and others are useless if not actually harmful. In any case their success or failure is largely a matter of chance. A hit-or-miss attack is fairly certain to miss. Of the ordinary preventives, preheating the feed water, filtration, use of kerosene, introduction of zinc into the boilers, and chemical treatment of the water either inside or outside the boiler are the most common. Most such remedies are only a partial success for they do not remove all the scale, while some of the inside chemical treatments really do more harm than good.

The writer would not intimate that a chemical compound cannot be satisfactory. For instance if a water, known to contain a reasonably constant proportion of sulphate of lime, were treated with the proper amount



Ill.; Paducah & Illinois R.R.
Modjeski, Consulting Engineer.)

of carbonate of soda, no hard scale would be produced. Grains of carbonate of lime would fall down but would adhere to the plates and could, therefore, be blown out or gathered into sediment collectors. Chemicals would be in better repute if they were used more intelligently but unfortunately they are seldom compounded with reference to all the local conditions. The damage done to boilers by unsuitable compounds is enormous.

In contrast to such doubtful remedies the graphite treatment is conspicuous. The principle upon which it works is rather unique. It does not prevent the formation and precipitation of solid matter but it coats the interior of the boiler below the water line with a slippery veneer to which the scale cannot adhere firmly. Particles of graphite also settle on the bits of scale as they form and make the deposit soft or crumbly. As a result boilers can be cleaned with remarkable ease. Men who have cleaned boilers with hammer and chisel, or turbine cleaner, appreciate the difference. The writer has in mind one case where formerly five men required three days to clean the 580 caps of certain water-tube boilers. Since using graphite three men clean them in one day. Instances of this kind are common.

Graphite has no chemical action whatever. One would hardly believe it possible that graphite can remove old scale that the so called compounds have failed to loosen. The theory of its action is interesting. From the inside of the boiler, scale is seen to be full of fine checks or cracks, appearing somewhat like alligator skin. Contractions and expansions of the shell and tubes loosen the small sections at the edges. Graphite being swirled around in the water finds its way into the cracks and gradually gets under the edges of the sections of scale, thereby preventing the edges from sticking to the metal again. Continual expansion and contraction, with graphite filling the cracks, loosen the sections still more; graphite creeps in farther until eventually whole sections of scale are separated from the metal and they fall to the bottom of the shell (in return tubular boilers) or may be easily rapped loose. The writer knows where scale has been thus removed from water-tube boilers in which it had accumulated so thick that there was only a small hole left through the center of the tubes. To be sure, it took considerable time. The particular plant in which this was done is one of the thousands in which compounds have been used for years but have failed to prevent scale.

Graphite will not cause pitting or corrosion, is an excellent conductor of heat, prolongs the life of gaskets, packings and valve seats at least ten times their usual life, and in no way affects the quality of the steam. This latter virtue is welcome in plants that require clean steam—such as canneries, laundries, ice plants, and sugar refineries.

In beginning a graphite treatment it should not be expected to bring down the scale overnight or even in a week. It is reasonable to wait from three to ten weeks, according to the thickness and hardness of the scale, before appreciable results may be expected. Boilers operated continuously yield to the treatment more slowly than those in which the fires are banked overnight because of great dependence upon repeated expansion and contraction of the metal to crack the scale. Ordinarily the new scale deposits as sludge or in small lumps that may be removed each day by blowing-off. A really clean boiler is almost unknown unless graphite is used. In certain exceptional cases where the water contains unusually large amounts of solids it may be advisable to use a carefully selected chemical in conjunction with graphite so as to be doubly sure of getting rid of the deposit.

The method of introducing the graphite into the boilers is essentially the same as in feeding compounds. It is introduced into the feed-water line, preferably on the suction side of the feed pump, whence the water carries it to the boilers. The advantage of placing the graphite in the suction line is that it then lubricates the pump valves and packing. The graphite is equally efficacious in lubricating any hot-water meters and in loosening the scale in feed-water heaters, though such benefits are incidental. Anyone can rig up a home-made device for feeding graphite into the pump suction. The apparatus can be made to inject a whole day's supply at one time or may be regulated to give down its charge of graphite slowly throughout the day. The latter method is the best for obvious reasons. If boilers are in a battery, care should be taken that each boiler receives its share of graphite.

The amount of graphite required depends upon the character of the water. Ordinarily from a pint to a quart per day of twelve hours is sufficient for a boiler of

up to 250-hp. capacity. Larger boilers need proportionately more. The daily amount may be decreased as soon as the old scale has been brought down. In certain boilers the feed water first enters a mud pan or drum, the purpose of which is to separate from the water as much of the suspended solids as is possible. Naturally the mud drum will collect much of the graphite and prevent it from entering the boiler. As a result the regular prescribed dose of graphite will not be sufficient where the above condition exists, because only part of the graphite is really utilized in the boiler proper. It therefore becomes necessary to feed the graphite slowly throughout the day and to use more than is ordinarily required; otherwise the effect of the graphite on the scale will be of little value.

In comparison with "compounds," boiler graphite costs no more and usually costs less. The expense is overshadowed by the savings from improved steaming conditions. It is rare that graphite will not increase the steaming capacity of boilers at least 25%.

Careful consideration should be given to the grade of graphite best adapted to boiler use. Graphite as found the world over is divided into two general classes: (1) flake or crystalline, and (2) amorphous or powdered. Amorphous graphite is valuable for certain purposes, such as foundry facings or stove polish, where its properties of balling up or sticking together are not objectionable. It is a fact, however, that this form due to the physical characteristics of the particles, to a certain extent forms a mud in the boiler and settles on the plates and tubes. On the other hand, experience has shown that the finely pulverized, thin flake variety will be distributed evenly on the surfaces of the shells and tubes and become more permanently attached to the metal than the amorphous. Both amorphous and flake graphite are employed, but investigation shows that those who manufacture and sell both grades, recommend the finely pulverized flake material in preference to the amorphous, although the margin of profit is approximately the same on both.

A Test Case on the New York Labor Law

The constitutionality of the New York labor law, enacted eight years ago, is to be tested by carrying a case to the Court of Appeals.

The law provides that any public contract shall be void and the contractor shall not be entitled to receive any money thereon, if he [illegible] or permits a laborer, mechanic or workman, in his employ to work more than 8 hours in any one calendar day, except in case of "extraordinary emergency caused by fire, flood or danger to life or property"; if he pays less than the prevailing rate of wages for such trade or occupation in the "locality" where the public work is being performed or erected; or if he employs persons who are not citizens of the United States, native or naturalized. The law vests no discretion in public officers and is mandatory in its penalty of forfeiture of contract for violation of its provisions [illegible].

These drastic provisions of the law have prevented [illegible] financial obligations [illegible]. The General Contractors' Association has therefore arranged to have test suits brought on three small contracts in Bronx Borough, New York City, where deliberate violations of the law were made to furnish groundwork for the suits.

Mr. Charles R. Crane, Secretary of the General Contractors' Association, has submitted the following statement respecting the evils growing out of the law, as it now stands:

The courts and public officials have adopted a very liberal policy in construing the law in such cases of alleged violation as have come before them. In the eight years that the law has been in operation but one contract has been forfeited for violation of the labor law, and in that instance the contractor's claim for damages was settled out of court by the municipality affected by payment of a substantial sum.

Repeated efforts on the part of the State Labor Department to secure convictions, after finding what appeared to be substantial evidence of violations of the law, have failed. The contractor has always been able either to prove that an "extraordinary emergency" existed, or by a "preponderance of evidence" to establish that the complainants were mistaken.

These complaints have been mostly on overtime charges, and many peculiar situations arise which emphasize the defect in the law with regard to the eight-hour provision. It forbids the employer, under heavy penalty, to permit or require an employee to work overtime, but an employee may violate the provision with impunity. It is no uncommon occurrence on large contracts for workmen to make extra time by working in two shifts without the knowledge of the employer. These men are identified by numbers, or brass checks, and it is a simple matter for a laborer to leave his gang a few minutes before quitting time and apply for work at another gang starting on the next shift at a point some distance from his first place of work. With another timekeeper and foreman, it is almost impossible to prevent this, and the explanation of the two checks at the pay window is that one is for a "friend who couldn't come."

Needless to say, no contractor wants a laborer to work sixteen hours at a stretch; he wouldn't permit it, and he certainly wouldn't require it. The laborer wants the money, and he knows he is violating the law, but the only punishment that can be inflicted on him is discharge. In such instances the contractor would not be held responsible and would be in no danger of losing his contract, but the operation of the law is such that he could be put to great inconvenience if the discharged workman filed a complaint that he had worked overtime.

This complaint would serve to stop all payments on the contract until an investigation of the charge had been completed. The contractor would have to employ counsel to conduct his defence, and as the minimum time in which these proceedings can be concluded is about six weeks, in many cases he would have to borrow money to continue his work to replace his withheld payments. His only redress, on being absolved of the charge, is recovery of interest on his payments for the period of their retention.

The provision that no money shall be paid out on a contract pending the investigation of a complaint is a most serious menace to contractors. It is cheaper to buy [illegible] to submit to blackmail even when innocent of violations than to stand the expense and delay of the investigation. The opportunity to embarrass a contractor is too easy to be overlooked by one having a grudge. Unprincipled competitors have been known to file [illegible] complaints which are just as effective in tying up payments as bona fide affidavits. Affidavits have been filed by discharged workmen, to be withdrawn later if their demands are granted. The special Supreme Court grand jury in New York County which investigated the contract situation on the Catskill Aqueduct and other [illegible] admitted as one of its [illegible]:

"That the provisions of the Labor Law, as now administered with respect to public work, are used [illegible] themselves to a use by the [illegible] for the purpose of [illegible] from contractors [illegible] such public works."

[illegible] that section of the Labor Law [illegible] requiring that the prevailing rate of wages shall be paid in the "locality" where the work is done. Not only is it difficult at times to determine what the prevailing rate is, but the determination of "locality" is open to argument. The [illegible] of the state [illegible] a [illegible] "locality" [illegible] of a city. [illegible] in New York City, the rate [illegible] by labor unions is not

uniform throughout for the same class of work. The highest rates prevail on Manhattan Island.

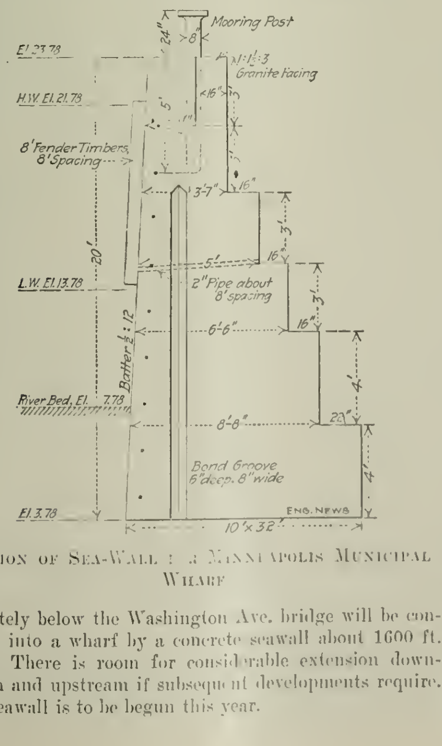
There is rarely a week that one or more complaints alleging that contractors are not paying the prevailing rate are not filed in the Finance Department, and only those persons who are familiar with the construction work now going on in this city can have any idea of the number of cases that are compromised under threat of complaint.

The test case involving the employment of alien laborers is highly important. It is true that this part of the law is honored more in the breach than in the observance, but it offers an opportunity as a "trouble maker" and has been brought up usually during ante-election campaigns to embarrass public officials who are candidates for office. While this law has been declared unconstitutional on two different occasions in this state, these opinions were rendered in trial courts and resulted in the acquittal of the contractor, thus rendering an appeal by the state impossible. The question therefore has not been passed upon by the highest courts, and the law remains on the statute books, fully operative whenever anyone sees fit to call it in use.

The officers of the General Contractors Association are: Franklin Remington, president of the Foundation Co., president; Edward S. Skillin, of Snare & Triest Co., first vice-president; Daniel A. Garber, president of the North Eastern Construction Co., second vice-president; William P. Schmuck, secretary of Degnon Contracting Co., treasurer; C. A. Crane, secretary.

Municipal Harbor Construction in Minneapolis

Improvement of the Mississippi River by a high-lift lock and dam half way between St. Paul and Minneapolis by the Federal government will shortly bring a navigation depth of 7 ft. up to Minneapolis where there has heretofore been only 2 ft. of depth. To develop all the navigation possibilities of this improvement the city of Minneapolis has designed and will shortly start building a municipal wharf. The right bank of the Mississippi im-



Section of Sea-Wall for Minneapolis Municipal Wharf

mediately below the Washington Ave. bridge will be converted into a wharf by a concrete seawall about 1600 ft. long. There is room for considerable extension downstream and upstream if subsequent developments require. The seawall is to be begun this year.

The river-gorge bluff is fairly close to the bank of the river along most of the length of the seawall, swinging back somewhat at the upper end in the vicinity of the bridge. Along the shore line, however, rock lies close below river bottom. The river bottom as it will be improved by dredging is at Elev. 7.78; rock is struck near this level all along the site of the wall, as test-pits have shown. A height of wall of 20 ft. from foundation to top is counted on as being adequate for all parts of the length. At one point a small run has cut a groove in the rock about 10 ft. below its general level, and this may require slightly deeper foundations.

The wall designed for this work, as shown in the drawing herewith, is a solid concrete gravity wall, with 10-ft. base for the 20-ft. height. It is to be constructed in lengths of 32 ft., separated by contraction joints. The wall will be backfilled level with its top.

The alignment of the wharfage involves a slight angle, about 1000 ft. from the upper end, the lower 600-ft. section swinging outward so as to form a hollow angle with the upper end. This is not likely to have any bearing on the use of the wharf however.

The city engineer plans to erect back of the seawall a warehouse 150 ft. wide, set back from the dock front sufficiently to give room for crane tracks and loading platform. No specific design for this part of the enterprise has been made.

The use of the wharf will require a certain amount of dredging in the river channel abreast of the dock. It is expected that the United States government will do this dredging outside of a line 10 ft. from the face of the seawall, to form a turning basin at the head of navigation.

The plans for the harbor development were worked out by the city engineer's department of the city of Minneapolis, F. W. Cappelen, City Engineer. An appropriation of $75,000 has been made by the city council, and work will start shortly. As in practically all other city work in Minneapolis this year, the day-labor plan of doing the work under direct charge of the city engineer's office will be followed.

NEWS NOTES

A 15-Ft. Sewer Trench Caved In when its shoring failed, in Montreal, Que., on July 20, killing one man and injuring another.

A Lifeboat Fell from Its Davits during a boat drill on the White Star steamship "Baltic," at Liverpool, on July 25, killing one man and injuring nine others. The boat fell 40 ft.

The Sunken "Empress of Ireland" has changed her position under the action of strong current, so that her masts are only about 35 ft. below the surface of the St. Lawrence River. Orders were given on July 24 to remove the masts with dynamite.

Burned Ties Wrecked the St. Louis, Iron Mountain & Southern R.R. mail train, one mile south of Diehlstadt, Mo., on July 21. Section men had been burning rubbish on the right of way and the fire had spread to the ties. Six ties were burned from under the rails at the point of the wreck, and a broken rail resulted when the train hit this point. More than 20 persons were injured.

A Broken Railway-Car Truck caused the wreck of a freight train on the East Penn R.R., at Macungie, Penn., on July 22, according to press dispatches. Twenty cars were involved in the derailment of the train, which consisted of 20 steel gondolas. The crippled car was the eleventh back of the locomotive, which went on with the front of the train. None of the train crew was hurt. A runaround was constructed.

A Broken Gas Main filled a manhole connected to a sewer, with [illegible] gas and caused the death of one person, recently, in Toronto, Ont. A main was broken by settling of the earth when the [illegible] was filled in. The gas passed from the manhole into the sewer. An engineer in the employ of the city was asphyxiated in the new sewer on Argyle St. from this cause. The contractor doing the work stated that the men knew of the presence of the gas four days before the death, and that the gas company had repaired the break a week before the death. Examination of the [illegible] indicated that death resulted from poisoning by carbon monoxide gas, which gas was present in the sewer in the proportion of eight parts in 1000.

Falling Structural Steel, which was being hoisted by a [illegible] to the 18th story of a new building being erected in Philadelphia by the F[illegible] Co. of Pennsylvania, blocked traffic for a half-hour by breaking a number of electric wires. The four steel members, weighing about a ton each and about [illegible] ft. in length, were suspended above the street when the [illegible] slipped. The beams struck the street, end on, ramming [illegible] a foot deep in the wood-block pavement. They rebounded in the air, falling against the trolley wires, which they bore down with them upon the track. Press reports state that [illegible] fastenings caused the accident. Just as the workmen were about to guide the four pieces into place one got loose, the others shot after it through the gap left in the [illegible].

High Wind Blew Down a 150-Ton Gantry Crane at the Marion power station of the Public Service Electric Co. of New Jersey on July 23. The crane which was parallel to the station, was blown along its track for a distance of about [illegible] ft., falling over on a yard locomotive. The span of the crane was 150 ft. and the length of the wheelbase 25 ft. Eight wheels on one side were locked by brakes. When the storm broke, the crane was standing at the western end of the [illegible] on a [illegible] dock on the Hackensack River. The wind started the crane, which acquired a high rate of speed along the level track, falling at the opposite end of the track. The tracks upon which the locomotive was standing were pushed about two feet into the ground. The damage is estimated at $50,000.

The crane had been in service 10 years. It handled coal from barges to storage piles and from the piles to the hoppers in the buildings.

Nearly a Half-Million Pounds of Dynamite Exploded—The [illegible] Powder & Dynamite Magazine maintained under the direction of the Depot Quartermaster at Mt. Hope, near the Gatun-Colon wagon road, about five miles from Colon, C. Z., was destroyed by an explosion at 9.[illegible] a.m. [illegible]. According to the "Canal Record," the magazine contained [illegible] lb. of dynamite and 15,3[illegible] lb. of Trojan powder. The [illegible] watchman was found dead about 72 paces from the magazine. The family of the night watchman, consisting of himself, wife and seven children, who lived in a small house about [illegible] yd. south of the magazine, escaped with slight injuries. The wall of the [illegible] house, about 180 ft. distant, was [illegible], allowing part of the roof to collapse. The shock from the explosion was felt in Mt. Hope, Colon and [illegible] and caused some damage in the way of broken glass, [illegible] life within a radius of several hundred yards of the explosion was destroyed.

The greater part of the powder and dynamite in the magazine was received [illegible] on May [illegible] since which time it has been inspected at required intervals and [illegible] The explosion is thought to have been due to spontaneous combustion.

The magazine was built into a hillside [illegible] at the back and sides it was surrounded by earth. The walls were constructed of hollow concrete blocks [illegible] ft. thick [illegible] the roof was of concrete reinforced with [illegible]. The building was [illegible] ft. [illegible] and [illegible] ft. high [illegible].

Two Steamers and One Large Sailing Vessel Went Ashore [illegible]

Other dispatches received at Halifax stated that the Austrian steamer "Irene" was ashore at Woody point, Pauline, and that the American schooner "Clarence C. Venner" crashed on the southwest ledges off Cape Sable. The crew was saved. The "Clarence C. Venner" was bound for Halifax from New York with 1300 tons of anthracite.

On July 19 the Italian bark "King Malcolm," bound from Portland, Me., to Richibucto, N. B., in ballast, was lost about seven miles from Yarmouth, N. S.

On July 18, the 3-masted schooner "Jennie A. Pickles," of Annapolis Royal, N. S., went ashore in a thick fog at Chance Harbor, in the Bay of Fundy. She was on her way from Bermuda to St. Johns, N. B., with a cargo of molasses.

June Floods Destroy Hundreds of Iowa Highway Bridges—May and June floods cost Iowa, it is estimated, $200,000 or more in damaged and destroyed bridges. What they cost in washed out grades and minor damage to highways, there is no possible way at the present time to even approximately guess. The estimate on bridge damage and loss is made by the field engineers of the State Highway Commission, who have been called to many counties by reason of the emergency work. The failures were due chiefly to two reasons, foundations insufficient and not properly placed reinforcing. In some cases of failure, the concrete material was of the best, but lack both of sufficient and properly placed reinforcing developed weaknesses that under ordinary circumstances would never have been detected. The washing out of creek and ditch bottoms, in some cases 9 or 10 ft. deep, disclosed many cases of the most woeful disregard of all engineering practices in the building of foundations. Concrete bridges were disclosed that had been resting on a thin film of black muck overlying quicksand. Many bridges went out for the simple reason that the wing walls were not securely tied by reinforcing to the abutment. This, with lack of depth in the foundation, allowed the flood water to sweep away the foundation of the wing wall, the lack of reinforcing allowed the wing to break from the abutment and topple, and with the fill melted away, the wrecking of the bridge was easy. Every concrete bridge wrecked had been built by bridge contractors on their own plans without other than their own inspection or by day labor by the counties themselves, sometimes on no plans at all. There is no record so far of a properly designed and constructed concrete bridge being destroyed.—[July "Service Bulletin" of the Iowa Highway Commission.]

Explorations for Two Dam Sites are being carried on by the Aluminum Company of America on the Little Tennessee River, near the Tennessee-North Carolina boundary. One of the proposed sites is just above [illegible], Tenn., and the other is nine miles above at the mouth of the Cheowah River, in North Carolina. The river runs through a deep gorge in both places. It is planned to develop [illegible] hp. to be transmitted to a reduction plant at Maryville.

Highway Work in Pennsylvania has begun in earnest. The release of the funds derived from the taxation and registration of automobiles, as noted in these columns of July 2, p. 52, amounts to about $1,[illegible], which can now be drawn upon by the State Highway Commissioner. According to newspaper reports no attempt will be made at new construction until repair and maintenance work has been accomplished. It is said between [illegible] and [illegible] men are already at work on the roads of the state.

Mesquite Wood Blocks have become so scarce that the city of San Antonio, Tex., has abandoned the plan of paving [illegible] sq. yd. of streets with this wood. The contract was let in April for over [illegible] sq. yd. of mesquite block paving, but the contractor has been unable to furnish the blocks. Mesquite is a very hard, tough, dense wood, almost indestructible, and has been used for the sills of adobe houses in the southwest for very many years. In many respects it makes an ideal material for paving.

Repetition of the Pittsburgh Sewer Explosion of Nov. [illegible], 1913 (see our [illegible], Jan. [illegible], 1914, p. [illegible]) occurred on Tuesday morning, July [illegible], 1914. It was a very small explosion compared with the [illegible] violent and extensive [illegible] of last November. The [illegible] St. [illegible] sewer near its outfall end was the seat of the explosion. The Lower [illegible] Mill of the Carnegie Steel Co. was slightly damaged. Repair and reconstruction work on the sewer has been going on [illegible] for the past seven months, the explosion of last November having destroyed a length of one mile of the sewer. This reconstruction is practically completed, some [illegible] had just left the sewer at the point of the accident when the explosion occurred.

A New Railway Bridge Over the Ohio at Scioteville is to be built by the Chesapeake & [illegible] Northern Ry. Co., a subsidiary company of the Chesapeake & Ohio Ry. The former company has asked permission of the War Department to erect a

bridge across the Ohio River a few hundred feet above the mouth of the Little Scioto River, at Sciotoville, Scioto County, Ohio. The bridge is to consist of two 750-ft. cantilever spans, with a south approach of 14 and a north approach of 11 deck plate-girder spans of 80 ft. each. Bids on the bridge have been called for.

The Road Congress at San Francisco—A general road congress, to be held at San Francisco during 1915, conducted jointly by the American Highway Association and the American Road Builders Association is being planned for. The plan was approved at a special meeting of the directors of the American Road Builders Association on July 17. The management of the joint meeting would be in the hands of a committee of five made up of two members from each association and a fifth member to be selected by these four. The meeting will probably be held immediately following the International Engineering Congress.

Six Large Contracts on the New York Rapid Transit system's extensions have recently been executed by the Public Service Commission. The aggregate amount of the six contracts is over $21,000,000. Two of these contracts were for the construction of the two East River tunnels, contract for which has been let to the Flinn-O'Rourke Co., an organization made up of the firms of Booth & Flinn, and the O'Rourke Engineering & Construction Co. A part of the Eastern Parkway subway in Brooklyn was awarded to the Cranford Co., the Canal St. subway in Manhattan to the Underpinning & Foundation Co., part of the Lexington Ave. subway in Manhattan to the Rapid Transit Subway Construction Co., and the Broadway subway from 26th to 38th St., to the United States Realty & Improvement Co.

The Record for Placing Concrete Masonry in Kensico Dam in the month of May, 1914, noted in "Engineering News," June 4, 1914, p. 1276, was surpassed in the month of June. The record is as follows:

Number of working days (8 hr.)	26½ days
Total masonry placed in dam, all kinds	76,970 cu.yd.
Average amount of masonry per day	2,905 "
Best day's work	3,314 "

Three gravity mixers, each taking 8-bag batches (nominal 2-yd mixers), were used for making the concrete. The average daily output per mixer, with no deductions for delays, was 669.7 cu.yd., or 83.7 cu.yd. per hour measured in place. Three-quarters of all concrete was mixed by two mixers located on the downstream side of the dam. The average daily output of each of these two mixers, with no deductions for delays, was 783.3 cu.yd., or 97.9 cu.yd. per hour, measured in place. The best day's output of one mixer was 1142.8 cu. yd., or 142.8 cu.yd. per hour, measured in place.

A Deep Water Diving Suit was tested in Long Island Sound off Stamford, Conn., on July 26, in a depth of 212 ft., which is probably a record for deep sea diving. The suit is in effect a metal casing, looking curiously like a suit of Chinese armor and jointed at the elbow, knee, hip and shoulder to allow movement of the diver. One arm is provided with a searchlight and the other with a grappling hook. The casing completely envelopes the diver and is of sufficient strength to resist pressures at least as great as that experienced in the test. According to the owner's reports, "no attempt is made to make the suit airtight, so that all of the water that works in through the joints is kept out by an automatic pump." Air for the diver is supplied through a pipe to the helmet, which pipe also contains a telephone wire.

The diver making the record was Arthur Gentsch, a well known deep-sea diver. The demonstration was under the direction of the Submarine Diving and Recovering Co.

An Electricity Rate of 18c. per kw.-hr. was recently protested to the Massachusetts Board of Gas and Electric Light Commissioners by the city of Northampton. An order of the Board governing the rates of the company in question, the Northampton Electric Light Co., has just been published. The company charged 18c. per kw.-hr. gross, for commercial supply, with a discount of 4c. for prompt payment, for the first 15 kw.-hr. For all in excess of 15 kw.-hr., the price was 11c. with 1c. discount for prompt payment. Net prices for power ranged from 6.7 to 3.0 per kw.-hr.; there were various special-service rates also. The prices for street lighting were $90 per year for all-night arcs, and $70 for midnight arcs with $5.56 extra per lamp for early morning operation. Several hundred 50-watt tungsten street lamps were used at $28 and $19 (all night and midnight). By special arrangement 12 street arches, carrying 208 50-watt tungstens were charged at $1200.

The company made a general reduction to 12c. maximum net commercial rate, $85 and $71 for arcs, and $21 and $18 for the 50-watt tungstens. The city asked for a general rate of 7c. per kw.-hr. for lighting, 5c. for street lighting and 2c. for power.

The Board reported that since 1888 (when the company began to report to the Board) the concern had failed to pay dividends in but two years. In only seven of the remaining had less than 6% been paid. In 1902, it began paying 8%, and in 1906, 10%. The annual dividends in the last five years had averaged over 20% and a surplus above interest, expenses and dividends of over $19,000 per year had been secured. The book value of plant and assets was $294,295, against which there were $206,878 in stocks, bonds and debts.

The Board fixed a rate of 9c. per kw.-hr. maximum net general rate; for arc lamps, $82 and $68; for tungsten street lamps, $17 and $13.50. The Board refused to touch other rates, holding that they were made from motives of expediency to obtain competitive business which could not otherwise be secured.

PERSONALS

Mr. F. L. Beal has been appointed Valuation Engineer of the Louisiana & Arkansas Ry., with offices at Stamps, Ark., under the direction of the General Manager.

Mr. W. A. Ebbert, formerly with the Pekin Wagon Co., Pekin, Ill., is now in charge of the dump wagon department of the Kentucky Wagon Manufacturing Co., Louisville, Ky.

Mr. Fitz J. Lewis, M. Am. Soc. M. E., Supervisor of the Pacific locks, Panama Canal, resigned, effective July 14, and sailed for New York July 16. He entered the Canal Service on Apr. 11, 1906, as a machinist in the shops of the Mechanical Division at Empire.

Mr. S. N. Mills, former Chief Clerk of the Block Signal and Train Control Board, Interstate Commerce Commission, has been appointed Inspector, and has been assigned to the work of investigating and testing signal and train control systems and other safety devices.

Mr. John L. Mohun, formerly with the mechanical department of the Pennsylvania R.R., is now Assistant to the Consulting Engineer of the Union Pacific R.R., the Oregon Short Line R.R. and the Oregon-Washington R.R. & Navigation Co., with headquarters at New York City.

Col. Henry G. Prout, M. Am. Soc. C. E., has resigned as President of the Union Switch & Signal Co., of Pittsburgh, Penn., to which office he was elected in April, 1914. A sketch of Col. Prout's career as a soldier, engineer, editor and business man appeared in these columns of Apr. 2.

Mr. E. L. Powers, Editor and owner of "Good Roads," New York City, and Secretary of the American Road Builders Association, was quite seriously injured in an automobile accident near Jamestown, N. Y., July 23. It is stated that he is now recovering and is resting comfortably in a Buffalo, N. Y., hospital.

Maj. G. A. Young, Corps of Engineers, U. S. A., has been appointed Professor of practical military engineering at the United States Military Academy at West Point, according to act of Congress, Apr. 15, 1914, which makes the head of that department at the Academy, hitherto known as Instructor, a Professor with the rank of Lieutenant-Colonel, U. S. A.

Mr. Charles D. Pollock, M. Am. Soc. C. E., has resigned as Chief Engineer of Highways, San Antonio, Tex., and has opened an office at 21 Park Row, New York City, as Consulting Engineer, specializing in paving. Before going to San Antonio, Mr. Pollock was Chief Engineer of Paving of Havana, Cuba. Previous to that he was with the Bureau of Highways of the Borough of Manhattan, New York City.

Mr. Henry R. Towne, Past-President, Am. Soc. M. E., President of the Yale & Towne Manufacturing Co., New York City, has been elected a Class B Director of the Federal Reserve Bank of New York, as a representative of commercial interests. The Class A Directors must be bankers. Mr. Towne has long been active in the affairs of the New York Merchants' Association and was President of that organization from 1908 until June, 1913.

Mr. Harold A. Petterson, Assoc. M. Am. Soc., C. E., Civil and Hydraulic Engineer, San Francisco, Calif., formerly Field Superintendent for the Union Oil Co. of California, left San Francisco, Calif., July 11, for China, where he has been appointed Professor of structural and hydraulic engineering at the University of Pei Yang at Tien Tsin. Mr. Petterson is a graduate of the University of California and was connected with the engineering staff of the Los Angeles aqueduct.

Mr. J. B. Lippincott, M. Am. Soc. C. E., of Los Angeles, Calif., has been selected by the Public Utilities Commission, of Denver, Colo., as its Consulting Engineer in connection with the proposed plan of constructing a new water-supply system for the city and county of Denver. Mr. Lippincott

[illegible] Chief Assistant Engineer throughout the construction of the Los Angeles [illegible]. The problem of providing a complete [illegible] system for Denver is very similar to the Los Angeles problem. Mr. Lippincott will undertake the preliminary [illegible] at [illegible].

[illegible] Cram, F. Am. Inst. Arch., of Boston, Mass., has been appointed Senior Professor of architecture at the Massachusetts Institute of Technology, succeeding Mr. [illegible] Knox Taylor, F. Am. Inst. Arch., resigned. Mr. Cram will continue in active practice and will devote only a part of his time to the Institute. Prof. William H. Lawrence, a graduate of the Institute and for many years Professor of [illegible], has been appointed Chairman of the Department of [illegible] and will be responsible for the administrative routine.

Mr. Max W. [illegible], formerly a Reclamation Service Engineer, of Hanford, Calif., has been appointed as one of the Assessors to determine the values of land along the Sacramento and San Joaquin Rivers, California, which will be taxable under the new "Flood Control" Bill. About 2,000,000 acres of river land, located in 14 counties, fall within the scope of the contemplated assessment. The project has already been approved by California, and the rivers and harbors bill, now pending in the national congress, if passed, will donate [illegible] to this undertaking.

The permanent staff for the operation and maintenance of the Panama Canal, which is soon to be opened for commercial traffic, is as follows:

Col. H. F. Hodges, M. Am. Soc. C. E., Corps of Engineers, U. S. A., is Engineer of Maintenance; A. H. Nichols, Office Engineer; Capt. W. H. Rose, Assoc. M. Am. Soc. C. E., Corps of Engineers, U. S. A., Electrical Engineer, Electrical Division, Balboa; [illegible] M. Wells, M. Am. Soc. C. E., Resident Engineer, Division of Municipal Engineering, Gatun; H. H. [illegible], M. Am. Soc. C. E., Civil Engineer, U. S. N., is Engineer of Terminal Construction, Culebra; F. H. Cooke, Assoc. M. Am. Soc. C. E., Civil Engineer, U. S. N., Designing Engineer; T. [illegible], M. Am. Soc. C. E., Engineer of Docks, [illegible]; J. A. Walker, Superintendent, Balboa; W. G. [illegible], Superintendent, [illegible]; [illegible] is Resident Engineer, Division of Dredging, Balboa; D. C. Nutting, Jr., Constructor, U. S. N., is Superintendent, Mechanical Division, Balboa; Capt. Hugh [illegible], U. S. N., is Superintendent of Transportation, Division of Canal Transportation; [illegible] D. E. Dismukes, U. S. N., [illegible] of the Port, [illegible]; Lieut.-Com. H. V. [illegible], U. S. N., Captain of the Port, Balboa; W. F. [illegible], Assistant Engineer, Lighthouse Construction, [illegible]; First-Lieut. A. H. Acher, U. S. A., is Assistant Engineer, Division of Fortifications, Culebra.

Mr. [illegible], M. Am. Soc. C. E., has resigned as Electrical and Mechanical Engineer, Panama Canal, and has returned with his family to the United States. He entered the Canal Service as Electrical and Mechanical Engineer on [illegible] 1906. During his period of service, he has been [illegible] with the [illegible] under the direction of Col. H. F. Hodges, formerly Assistant Chief Engineer, and since Apr. 1, Engineer of Maintenance, of the machinery and electrical equipment for the operation of the canal locks, spillways, and power plants, including the [illegible] station at Gatun, the substations at [illegible], Miraflores, and Balboa, and [illegible] transmission line. [illegible]

[illegible]

City. He was given a farewell reception by the Tivoli Club on Saturday evening, July 11, and by the University Club, on Wednesday evening, July 15. [From the "Canal Record," July 1[illegible].]

OBITUARY

William Yearlen, a young civil and mining engineer of Boulder, Colo., was drowned while swimming in a reservoir near Boulder, on July 10. He was formerly in mining work in Mexico. He was 26 years old.

W. S. Hecker, former Assistant to the President of the Norfolk & Western Ry., and for many years General Superintendent of the Western division of the railway, died July 19 at his home in Bluefield, S. C.

Marc Spencer, a young civil engineering graduate of the University of North Carolina, was killed July 21, by a fall while employed on construction work for the Southern Aluminum Co., at Salisbury, N. C. He was [illegible] years old.

Horace Crosby, M. Am. Soc. C. E., of New Rochelle, N. Y., died July 21. He was one of the founders of the city's public library and was at one time President of the Board of Education. He was one of the oldest members of the American Society of Civil Engineers, having been elected in 18[illegible].

David O. Fowler, President of the Uvalde Asphalt Paving Co., New York City, died at his summer home in Lawrence, Long Island, N. Y., July 2[illegible], aged [illegible] years. He was a great grandson of Admiral Comte de Grasse, the French naval ally of Washington in the Yorktown campaign which ended the Revolutionary War.

Horace H. Moses, an old-time civil engineer and in the early 80's Superintendent of Sewers of Boston, Mass., died at his home in Roxbury, Mass., July 21. He was born at Exeter, N. H., in 1831. In 18[illegible] he went to Boston and entered the office of a civil engineer. During his later life he devoted much time to landscape architecture.

William Perry, a [illegible] engineer whose experience dated back to the earliest days of American railroading, died July 23, at his home in Rochester, N. Y. He was born in Wales in 1821 and emigrated to America with his parents in 1828, when he was 7 years old. The family settled in [illegible], N. Y., where young Perry attended school until he was [illegible] years old, when he went to Rochester and entered the employ of the Auburn & Rochester R.R., [illegible] the New York Central & Hudson River R.R. He continued in active service from 18[illegible] until 18[illegible].

VOLUME 72 AUGUST 6, 1914 NUMBER 6

The Savannah River Levee, Augusta, Ga.

By Nisbet Wingfield*

SYNOPSIS—An eleven-mile earth levee, with reinforced-concrete bulk-head gates and retaining wall is being built by the city of Augusta from a point just above the city to and for three miles through the city and to a point eight miles below the city where it meets a bluff. Before describing the levee the causes which demand its construction are given.

※

The Savannah River heads in the Blue Ridge Mountains between Tennessee and North Carolina and flows southeasterly to the Atlantic Ocean. Located 202 miles from Savannah, or 220 miles from the mouth of the river, is the city of Augusta. From the head waters to Augusta, the river and its tributaries flow through a mountainous country, the highest point being 1600 ft. above sea level and the elevation at Augusta being 105 ft. Augusta is at the foot of the hills or "fall line" and from this point to the ocean the river flows through the coastal plane.

The total drainage area above Augusta is 7295 sq.mi., the rainfall from which quickly finds its way to the main stream. The extreme low flow of the river, at Augusta, during a record of 10 years, is 2300 cu.ft. per sec.; the ordinary low flow is 5000 sec.-ft. In times of greatest flood the river has a volume at Augusta of 300,000 sec.-ft. When these floods come, the water is kept within or near the river bank, on account of the high hills on each side, until it reaches the city of Augusta, which is located at the foot of the hills on the plane on the Georgia side of the river. On the South Carolina side, the foothills continue for some miles below the city, but on the Georgia side they stop abruptly at the upper limits of the city and there is no high ground until a point eleven miles further down is reached. This makes a gap through which the flood waters pour after the river reaches the stage of 34 ft., and the flow is directly through the business and manufacturing section; the flow passing to the low ground south of the city. On these occasions the entire business district and many miles of residence streets are under water, the depth of the overflow varying from 3 to 15 ft., according to locality. The loss of life and property at times have been tremendous. As the water flows in along the entire river front of the city, which is three miles, and also backs in from below the city, the only feasible method of protection was by a levee to be started at the high ground just above Augusta and continue down the river a distance of 11 mi. to a natural bluff on the river bank.

The city owns a water-power development which fur-

FIG. 2. REINFORCED-CONCRETE BULKHEAD, WATER-CONTROL

FIG. 3. LOCATION OF LEVEE FOR THE PROTECTION OF AUGUSTA, GA.

nishes all mills in the city with water power. This development was made 35 yr. ago before the hydro-electric method was thought of. There is a diverting dam (see map, Fig. 3) across the river seven miles above the city and a canal 150 ft. wide leads from this into and through the corporate limits of the city. The levee starts at the bank of this canal just above the city. At this point, emergency gates (Fig. 2) will be put in the canal to cut off the flood water from that direction if the river should back into the canal, as it has done during periods of high water. From this point the levee will go downstream, following closely the river bank, going between the mills and various other industries along the river bank and the river proper.

The ground on which the levee is being built was occupied by the railroad terminals, numerous mills and factories and a number of residences, all of which were bought by the city and moved to new locations.

As already stated, the maximum flood passing Augusta has been 350,000 sec.-ft. We have had four floods almost identical as to volume, but the record of rainfall over the watershed indicates that each of the several floods came from heavy precipitation on only a portion of the watershed and in no instance from the same area.

In determining the height of the levee, we provided for heavy rainfall over the entire watershed, which would bring the discharge at Augusta up to 400,000 sec.-ft. and the entire structure is designed to safely withstand this amount of flood.

The general construction of the levee is an earth fill sloped 3 to 1 on the river side and 2 to 1 on the land side, except at certain points where there was not sufficient space between the mills and the river. At these points reinforced-concrete retaining walls have been built

GATES AND LOCK IN AUGUSTA POWER CANAL AT HEAD OF LEVEE

on the land side and regular earth slopes carried out on the river side. The height of the embankment varies from a maximum of 46 ft. to a minimum of 10 ft. After passing through the city limits the levee will run eight miles downstream. The location is through hay farms, cotton fields and swamps.

At points where streams are crossed there have been constructed reinforced-concrete bulkheads with steel gates

FIG. 1. SIBLEY MILL BULKHEAD AND GATES

(Of reinforced concrete, 59 ft. high above foundations. The openings are 8x20 ft in the clear. View taken from river side.)

[illegible] views, Figs. [illegible] and [illegible]). All bulkhead foundations were [illegible] to solid [illegible].

At the [illegible] bridges crossing the Savannah River, additional spans have been constructed on the Georgia side of the river [illegible] on top of the levee. Proper approaches have been constructed by raising the roadway. At the point where the Southern Railroad is crossed, a gate will be put in with an elevation 6 ft. above the track. The C. & W. C. R.R., two miles below the city, will be raised to meet the level of levee.

The fill through the city will require [illegible] cu.yd. of earth, all of which is being hauled in by train from a borrow pit outside the city limits. From the eastern city limits to Butler's Creek, the fill will be made of earth borrowed along the line of the fill and the construction will be with scrapers. The slope along the city front is being paved with stone. That portion of the levee outside the city limits will be planted in Bermuda grass.

The pavement which is now being constructed is 18 in. thick, there being placed first a layer of crushed granite 6 in. thick, on top of which are laid stone slabs 12 in. thick, making a total of 18 in. This pavement was started at the bottom of the river at the toe of the natural bank, where a trench running parallel to the bank has been dredged 10 ft. wide to rock bottom. In this has been dumped heavy stone weighing from [illegible] to [illegible] lb., the same being brought up to an elevation that will intersect with the bank slope. From the shore side of this trench rock, the pavement is started and carried on over the entire bank and berm, without a break, to the crown of the levee.

The concrete retaining-wall at the Riverside Mills, [illegible] ft. in height, is carried on piles. Beneath this wall, sheet piling has been driven 27 ft., or practically to a level with the bottom of the river, in order to cut off a strata of running sand. This covers a space [illegible] ft. in length.

The sanitary and drainage systems of Augusta have heretofore all entered the river at various points along the [illegible] river front. We have 12 of these outfalls. To take care of the drainage during periods of high water without the necessity of constructing gates, it was determined to construct a new outlet emptying into the river eight miles below the city, at which point the flood level is not sufficient to back the water into the city. To accomplish this a drainage ditch 30 ft. wide and of varying depth has been constructed from the city to the river eight miles below. A large intercepting sewer is being constructed which will take all of the water passing out of the 12 outfalls and deliver it to this drainage ditch beyond the southern limits of the city. This will eliminate all openings through the levee, except at the large bulkheads at Sibley Mill, King Mill, Hawks Gully and the Southern Railroad. This sewer is being constructed of reinforced concrete, because at times there will be back pressure.

The total cost of the work, including right-of-way and paving the bank on the river side, will be approximately $2,500,000. The work has been divided into different contracts, varying in amounts from $50,000 to $[illegible],000, so that firms of moderate means can bid. In this way we are saving at least 10% of the estimated cost. Five contractors have completed jobs aggregating $[illegible], and other contracts are being let from time to time. A considerable part of the contract work was done by A. J. Twiggs & Son, of Augusta. Everything is going with a rush and we hope to have the city protected from all but highest floods by Jan. 1, 1915, and fully protected from all floods by Jan. 1, 1916.

Approximately $1,000,000 has been spent on the levee so far and recently the city voted $750,000 additional. The work is being done under a special board, called the River and Canal Commission. The writer is Chief Engineer and J. F. Parker is Principal Assistant Engineer of the work. The plans for the bulkhead were made by Charles A. Maxwell, of Augusta.

Fig. 5. Reinforced-Concrete Retaining Wall at Riverside Mills
(The wall is [illegible] ft. high and is supported on pile foundations.)

A Vibration Measuring Instrument, known as the [illegible] Vibrometer, was described in the London "Engineer" of [illegible]. The purpose of the instrument is to measure vibrations in rapidly moving machinery such as turbines or electric generators. The principle of the instrument is the tuning of a metallic reed until its response to the vibration which is to be measured. This does away with the necessity of obtaining some fixed stationary point [illegible] the machine to be measured.

Water-Level of the Great Salt Lake

By J. Cecil Alter*

The maximum stage of the Great Salt Lake, Utah, was reached June 10 to 15, 1914. It exceeded the crest stage of 1913 by 6 in. Last year the highest stage occurred during the latter part of May, and in 1912, during the last week in June, which is the average time for the high water to occur. The lake is averaging higher now than at any time since the middle eighties, long before the Saltair Beach bathing pavilion, near Salt Lake City, was built, and which stands now about 1200 ft. out in the lake in five or six feet of water.

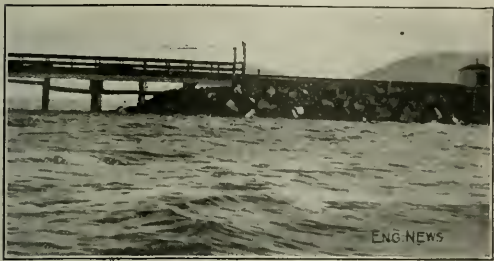

Fig. 1. East End of 11-Mi. Trestle of Southern Pacific Ry.

The oscillation of the lake, annually, amounts to about 1½ ft., though yearly oscillations have been as great as 3.6 ft.—from November, 1906, to July, 1907—and oscillations as small as one foot have been noted within the 11-yr. period of careful observations.

Beginning in June, the stream flow into the lake is being more and more utilized for irrigation purposes, and the stream supply from mountain snow is being more and more depleted, so that the amount of water flowing into the lake diminishes very greatly, besides this being the period of least rainfall over the Great Basin region. The loss of water from the lake by evaporation is greatest beginning in June, because of the increased heat, the greater number of hours of sunshine per day, and the increased velocities of the wind blowing over the lake.

These influences cause the lake to fall until the early half of January, each year, at which time the average wind velocities have lessened greatly, and other evaporation factors have become greatly lessened. This period of falling water usually covers about seven months. The rise takes place usually in a little more than five months. The greatest amount of precipitation over the Great Salt Lake watershed occurs in the spring; and with the melting snows and consequent rising streams, of March, April and May, the lake makes rapid rise to its crest stage.

The Engineering Department of the Oregon Short Line R.R. has kept a record of the semimonthly gage readings of the lake at Midlake station on the Southern Pacific Co.'s trestle, and at Saltair Beach, and of the rainfall over the contributory watersheds, together with the stream discharges into the lake, and the amount of snow accumulating and remaining in the mountains, as determined from Weather Bureau reports and bulletins.

The railway companies crossing the lake, both in the middle and at the southern extremity, are very much interested in the lake fluctuations because of the millions of dollars' worth of grade, trestle, track and improvements in the lake, for, not only do they wish to know where the water line will be on the grades and trestles, but stormy weather is much more to be feared when the lake is high than when low, as the wave action is much more serious, and wind tides are more disastrous.

About 16 mi. of the Great Salt Lake cutoff of the Southern Pacific Ry., between Lucin and Ogden, Utah, is over dry lake bed; 11 mi. is wood trestle across Great Salt Lake (Figs. 1 and 2). The first piles for the construction reached the lake in July, 1902. The rate of progress reached as high as 1140 ft. of trestle per day. Work was carried on from both ends and the juncture was effected Nov. 13, 1903. The construction of the Great Salt Lake cutoff is described in full in Engineering News, Feb. 27, 1902, p. 175 and Nov. 27, 1902, p. 442.

The resort companies in times past have found it necessary to rebuild or remove many expensive bathing houses and piers because of the changes in level.

The salt harvesters are also interested because their dirt dikes along the shore, inclosing the evaporating ponds, are sometimes endangered in high-water times, when strong wind tides are produced in wind storms of long duration.

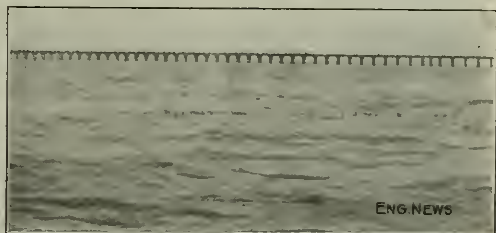

Fig. 2. Portion of the 11-Mi. Trestle

They are also interested in the probable depth of the water because the density of the brine has varied from about 25% to 20% solids, during the past 11 yr. The salt contents of the lake remains about the same, though it is diluted in time of high water, requiring the pumping of more water into the ponds, and longer waiting for it to evaporate, to obtain the same amount of salt.

*United States Weather Bureau, 1103 Boston Building, Salt Lake City, Utah.

Ohio Highway Facts—Ohio has (approximately) 83,700 miles of public roads outside of municipalities; 28,413 miles are improved. Of 11,000 miles of streets within the limits of the various municipalities, 6360 miles are improved. Some 573 miles of road improvement have been contracted for from the organization of the State Highway Department, in 1905, to November, 1913; 373 miles were contracted for during the last three years—up to and including Nov. 15, 1913; 103.7 miles of additional improvement have been contracted for from Nov. 13, 1913, up to the present time. Petitions had been filed for 7047 miles of improvement up to Jan. 1, 1914. The State Highway Department expects to improve approximately 500 miles of roads before the close of 1914. More than 55,260 miles remain unimproved. Ohio ranks third among the states in the percentage of public roads improved. Concrete roads have been built in 29 of the 88 counties of Ohio. Brick roads have been built in 39 counties. Cuyahoga County has the greatest mileage of brick roads (172.9). Huron County has the greatest mileage of concrete roads (16.0).—[From the June "Ohio State Highway Department Monthly."]

Washington Street-Cleaning Field Methods

By J. W. Paxton*

SYNOPSIS—This article is a continuation of the preceding one by Mr. Paxton in Engineering News *of July 9, 1914, p. 58, which described the cost-keeping methods. The following article describes in detail the field methods—the hand patrol; the machine-broom work; squeegee washing; flushing; suburban street cleaning and alley cleaning. Snow removal is briefly described. The stables and supply and repair divisions are included.*

The territory taken care of by the Washington Street Cleaning Division includes all of the streets in the city, certain suburban sections with gravel, macadam or unpaved streets and an extensive alley system.

The city is divided into two sections with approximately the same amount of cleaning in each. Almost in the center of one of these sections is a stable, the main storeroom, and repair shop; a second stable, auxiliary storeroom, and repair shop, are nearly in the center of the other section.

To meet the different conditions and requirements, cleaning is of several classes, such as Hand Patrol, Machine-Broom Cleaning, Alley Cleaning, Suburban Cleaning, Flushing, Squeegeeing, Oiling and Snow and Ice Work.

Hand Patrol

The hand-patrol area consists, at the present time, of approximately 3,[illegible] sq.yd., or about [illegible]% of the total paved area of the city. It includes practically the entire business section and considerable residential territory adjacent thereto.

Sections—This area is divided into five sections of from approximately [illegible] sq.yd. to [illegible] sq.yd. Each section is under a foreman with a force ranging from 32 men and 2 wagons to 57 men and 3 wagons, the total force employed being 221 men and 13 wagons. The average area per man is about 13,000 sq.yd., which is somewhat larger than reported for other cities, probably due to the frequent washing given the streets, to the fact that Washington has very little commercial traffic, and that men are employed strictly on merit. Each gang may cover its territory several times during the day, but the area is only credited once for a full day's work; one-half for one-half day's work, etc. At the end of the month, the total area credited is divided into the total cost charged, for each gang, giving the unit cost.

Subsections—Each foreman divides his large section into subsections to be worked by one, two, or five men. The area per man is dependent on the amount and character of traffic, the presence of car tracks, the sanding of car tracks, kind and condition of pavements, grade, surrounding population, [illegible] of unpaved streets, and the force available.

The one-man section is generally located in the suburbs where little dirt accumulates, and a large territory may be covered; the man sweeps, pans and sacks the dirt as he goes along. The two-man section is standard; the more active man uses a pan-scraper, broom or hand machine and deposits the dirt in the gutters; his partner with a bag carrier, collects the material so deposited, and sweeps the gutters clean.

The five-man section is used on broad, heavily traveled streets, where the area is large in proportion to the gutter length. The method here employed is similar to that on the two-man section, two men with bag carriers collecting the dirt deposited in the gutters by the other three.

Section Maps—The original development of the subsection is left to the foremen. The limits of each subsection and the number of men employed are reported to the office where the areas of each subsection and the areas per man are computed. This information, together with

Fig. 1. Hand Patrol Gang at Work, Showing the Pan Scraper, Hand Machine, and Bag Carrier Used in Washington; the Wagon Is Collecting the Filled Sacks

*Superintendent of Street Cleaning, Washington, D. C.

the amount of dirt collected per man, is plotted on a map, which is studied and rearranged in the effort to obtain a uniform task for each man.

RELATION BETWEEN AREA AND DIRT COLLECTED—The relation between area and dirt collected is theoretically an inverse ratio; other things being equal, that subsection showing the greatest area per man should accumulate the least dirt per 1000 sq.yd., while the minimum area per man should show a maximum of dirt collected per 1000 sq.yd. Frequent conferences between the office force and foremen are held to make and receive suggestions as to the best size of subsections.

The area of the subsections established, ranges from 6000 sq.yd. in the market section to 52,000 sq.yd. in the lightly traveled residential sections. The amount of dirt removed per day per bag carrier runs as high as 200 sacks during leaf season, and again as low as 8 or 9. The average per bag carrier per day lies between 10 and 20, each sack holding about 2 cu.ft.

HAND PATROL VS. MACHINE WORK—Experiments have been made as to the relative cost of machine work and hand patrol. It was found, in most cases, that the streets were kept in better condition, when the same amount was expended on hand patrol as on cleaning by machine brooms every other day.

In hand-patrol work, where the traffic conditions are variable, the distribution of the men can be increased or diminished accordingly. The greatest attention is given to the portions of the streets which need it the most, and the attention is continuous, the streets being just as clean at one time as at another.

With machine-broom sweeping, however, the entire section and every portion of each street must receive the same amount of sweeping. The streets present a good appearance immediately after the passing of the brooms, but become more unsightly than in hand-patrol work before the next cleaning, as the interval is much longer.

The machine broom raises so much dust that heavy sprinkling is required; the fine dust mixes with the water into mud, which is smeared on the street by the broom, and on drying, turns back to dust. The brooms only sweep the coarser particles and many of these are thrown over the broom by centrifugal force, back to the pavement again.

The policy of the division has therefore been to curtail the machine-broom area, whenever possible, in favor of the white wing work, supplemented, as funds are available, by washing in the more important and heavily traveled portions of the city.

SMALL POWER-OPERATED BROOMS—In hand-patrol work, a large proportion of the energy and time is consumed in traveling from one dirty portion of a street to another, particularly after the streets have been cleaned in the morning, or on streets where the traffic is light.

In an effort to increase the efficiency of this work, experiments have been tried with a light motor-driven tricycle, operated by one man. The broom is rotated by the engine, when lowered to the pavement, so as to brush the dirt into a pan receptacle; but it is disconnected, when raised, for traveling. A scraper in front of the broom loosens dirt which is stuck to the pavement.

This machine deposits the dirt in the gutters, and white wings equipped with bag carriers collect it as well as clean the gutters. The machine is still in the experimental stage, but the results obtained have been very encouraging. It may be possible eventually, by the use of a conveyor, to lift the dirt into bags or cans carried on the machine, doing away with hand-patrol work entirely.

SUPERVISION OF HAND-PATROL WORK—Motorcycles have been used to reduce the overhead expense of the hand-patrol work; three of the foremen supplied with these machines, take the places of four using bicycles, and they supervise a somewhat larger area. It is expected that another rearrangement of the white-wing area will shortly be made and the supervisory force reduced to four men, each equipped with a motorcycle, where six men with bicycles were formerly required. The foremen are very well satisfied with the machines, each making an average of from 50 to 80 miles per day.

HAND-PATROL EQUIPMENT—The equipment used on hand-patrol work consists of bag carriers, hand machines, pan scrapers, bamboo push brooms, sacks, shovels, sprinkling cans, etc. The dirt collected is placed in sacks which are collected in wagons manufactured by the Department. The question of building underground pits to hold the accumulation of street sweepings is being considered, but the initial cost would be so large that money is not available at the present time for this purpose.

The hand machine consists of a revolving bass broom mounted on wheels between two metal boxes, its action being exactly similar to that of a carpet sweeper. It is especially useful for removing fine dust on smooth pavements, but pan scrapers are found to be more generally useful.

MACHINE-BROOM CLEANING

The machine-broom area consists of approximately 2,000,000 sq.yd. or 43% of the paved area of the city; this territory is almost entirely residential. Some of the streets with heavy traffic are cleaned daily, others with very light traffic are cleaned three times in two weeks, while the majority are cleaned every other day.

The force employed in this work consists of two gangs of one sprinkler, three machines and four carts, and one gang of two sprinklers, six machines and seven carts, sufficient broom men being provided to pile the dirt swept to the gutters by the machines, the number of broom men depending on the general conditions of the territory under attention.

SUPERVISION OF MACHINE WORK—The supervisory force maintained for this division of the work consists of four foremen; one with a buggy for each three-machine gang, and two—one with buggy and one with motorcycle—for the six-machine gang.

Previously, four gangs of three machines were used, but it was found that while the machines were being closely observed, the cart men were practically left to themselves, it being impossible to follow both the machines and carts and make the necessary trips to the dumps. Two of these gangs were, therefore, combined, the machines being put in charge of a foreman with a buggy, while the carts worked under the direction of a second foreman with a motorcycle. This arrangement has not materially increased the yardage cleaned, but the foreman with the motorcycle has been able to give such attention to the carts that his force has been reduced from eight to seven.

METHODS OF OPERATION—The ratio of one sprinkler with three machines was found by experiment with odometers in connection with the cost keeping to be the most

Fig. 2. Machine-Broom Street Cleaning Gang; Washington, D. C.

efficient for local conditions. Under the contract system the organization of the gangs varied from one sprinkler with three or four machines to two sprinklers with five machines. These different combinations were tried out and it was found that higher unit costs were obtained with the one-three than with the one-four combination; but in the latter case the distance traveled by the sprinkler horses, in order to keep up with the machine, was prohibitive. The one-three combination gave a uniform distance of about 25 miles per day, for both machines and sprinkler, while the two-five combination favored the sprinkler as to distance traveled and gave still higher unit costs.

The mode of operation followed is for the sprinkler to precede the machine some little distance, the valves being stopped so that only enough water escapes to lay the dust and at the same time not cause mud. The machines follow each other, overlapping slightly, each street being swept from the center toward the curb.

It takes about two full working days for each gang to sweep their section. Sweeping must be done continuously from the time of leaving the stable until the return and in order to do this one side of the running street is swept going out, leaving the other side to be swept coming in. After reaching the territory, the order of sweeping is arranged as seems best in the judgment of the foreman at the time. An effort is made, however, to reduce the amount of turning to a minimum and always to sweep toward the dumps.

Each machine averages about 85,000 sq.yd. per day, the records, however, show spurts as high as 100,000 sq.yd. It should be noted that this class of work is harder than any other on live stock, although the draft is light, possibly due to the fact that the animals have no breathing spells or variation in work.

In leaf season, no additional machine work is required. The carts, however, have a much greater bulk to handle although the additional weight is very little. To care for this, all machine carts are provided with side and end boards of light weight, which fit on the flareboards, increasing the capacity of the cart about 2½ cu.yd. After leaf season, these tops are removed and stored for the next year.

Squeegee Washing

The area covered by the squeegees comprises about 1,766,000 sq.yd. of the smoothly paved streets in the white-wing section, being about 61% of the total white-wing area. The force employed on this work consists of three gangs, each under a foreman, and composed of one

Fig. 3. Squeegee Street-Cleaning Gang; Washington, D. C.

sprinkler and three machines, the territory being covered about twice per week. During the winter months, this force is decreased to two gangs of one sprinkler and three machines each, the interval between washings being correspondingly increased.

METHOD OF USING SQUEEGEES—The ratio of the number of machines to a sprinkler has been worked out in a manner analogous to that described under machine-broom cleaning, this combination proving the most economical. When filled, each squeegee carries as much water as an ordinary sprinkler, the broom must be dragged along the pavement and also revolved in the opposite direction to this motion; so it has been found advantageous to use three horses with each squeegee in the battery which works in a hilly section of the city.

Squeegeeing about twice per week almost entirely eliminates a fine scum which becomes plastered to the pavements, particularly sheet asphalt, which is not apparent when the pavements are dry but rises up in a thin sheet of mud when moist, making the pavements very slippery. This and fine dust cannot be removed by the hand cleaners.

Washington having a comparatively high-pressure water system, the machines used are of the hydraulic compressed-air type, and on the streets which are dirtiest will clean approximately their own width. Each filling is sufficient for a swath of about 500 ft. in length.

METHODS OF OPERATING FLUSHING MACHINES—The flushing machines are operated like the squeegees, each machine taking up the wave from the one in front and forcing it 7 or 8 ft. further toward the curb. Operated in this way, they are very efficient, but the cost of cleaning is about three times as much as squeegee work, so flushers are only used on streets unsuitable for squeegees.

It has been observed, in some other cities, that streets are said to have been flushed if one trip through has been made with a single flusher, and from the low cost of flushing reported from other cities, it is assumed that this is the method there pursued. Experiments here, indicate that this amounts to little more than sprinkling, although the pressure developed from the hydrant is always at least 45 lb. per sq.in.

Flushing being resorted to only on other than good sheet-asphalt streets, the territory is necessarily scattered

FIG. 4. FLUSHING GANG; WASHINGTON, D. C., STREET CLEANING DEPARTMENT

The sprinkler with the valves wide open precedes the squeegees at some little distance, the object being to thoroughly saturate this scum and soften the dry material on the street for removal by the squeegees. The machines follow each other as closely as possible, each machine receiving the dirt mixed with the water from the machine in front, and carrying it the width of the broom toward the curb.

The dirt deposited in the gutters is collected by the white wings, the cost of the collection being charged to that class of work, squeegeeing being considered an adjunct to the hand-patrol system and the charge for removal made on the theory that, were no washing done, this accumulation would have to be removed by the hand-patrol force.

FLUSHING

The flushing area comprises all worn and block pavements in the white-wing section, the entire territory totaling approximately 300,000 sq.yd. or 11% of the total white-wing area, each street being flushed about twice weekly by a gang of one foreman and three machines, three horses being used in each.

and it is impossible to arrange running streets or eliminate dead travel as is the case with other machine apparatus. The daily task performed only amounts to about 30,000 sq.yd. per machine.

CLEANING AND OILING SUBURBAN STREETS

The suburban territory consists of approximately 1,500,000 sq.yd. of water-bound macadam or unpaved streets. The object of this work is to keep the gutters clean, remove all trash, ravelings and weeds. Two gangs, each having a foreman with bicycle, ten men and four carts are employed.

DUST LAYING—In the fall of 1911, experiments in dust laying were tried on certain suburban streets, with calcium chloride and emulsified oil, instead of sprinkling with water, resulting in the decision to use only emulsified oil in the future.

In the spring of 1912, practically all of the suburban streets were thoroughly cleaned and swept with a sweeping machine, without sprinkling, before an application of oil was made. From then on applications of a mixture of about 1 gal. of oil to 6 or 7 gal. of water, spread in the proportion of approximately $^1/_7$ gal. of the mix-

yard to 1 sq.yd., were made about once every ten days or two weeks, the streets being cleaned with hand brooms previous to each application.

By this method, the dust nuisance was almost entirely eliminated. Less money was spent for sprinkling and oiling than for sprinkling alone during the previous year. Less suburban street cleaning was necessary, on account of there being less dirt and dust to be removed, and the general appearance of the streets was very much improved.

By the oiling method only enough equipment is required to cover the entire territory about once every ten days or two weeks, while by the sprinkling method it was necessary to carry enough equipment in wet weather to cover the entire territory two or three times a day in dry weather.

Only applications of light or emulsified oil will probably be made in the future, as dust laying and not road maintenance is the object in view, and where heavy oil is used in the city, many complaints are received on account of its being tracked into the houses.

Alley Cleaning

The alley system of Washington comprises approximately 1000 alleys, the majority being wide and well paved, the area amounting to about 1,000,000 sq.yd. The cleaning is done by three gangs, each under a foreman with a bicycle; two consisting of a sprinkler, one-horse sweeping-machine broom, three carts and six laborers; the other being a small hand gang of one sprinkler, three carts and four laborers, cleaning mostly narrow and very dirty alleys.

One-Horse Machine Brooms—After the contract system was abolished (previous to which all alleys were cleaned by hand), it was found by experiment, that many alleys could be most economically cleaned by one-horse sweeping machines. A chart of the daily yardage cleaned by two of the gangs, for six months after taking over the contract work, was plotted and studied. The foremen were then called to the office and this chart explained and suggestions invited.

As a result of this conference, entirely new schedules were issued in which the alleys were arranged in an approximate circle. These schedules were put in operation and an immediate increase in area cleaned resulted. Later squares containing alleys were classified as follows: those in which the alleys were paved and could be swept entirely by machines, by machines with one hand shaft, by machines with two or more hand shafts, or by hand; and those in which the alleys were partly paved or unpaved.

Classification Map—On a map of the city, all squares corresponding to the first classification were colored in red, to the second, in green, and so on, using a different color for each classification. Two alley schedules to be cleaned by machines, were then traced out, containing, as far as possible, all the squares in the first three classifications, and another schedule to be cleaned by hand, containing the balance of the squares.

An attempt was made, in each case, to arrange the squares in such order as to minimize the distance from the outlet of the alley in one square to the entrance to the alley in the next. Of course, where hand alleys were isolated and surrounded by machine alleys, they were absorbed in the machine schedule, and machine alleys were, in many cases, included in the hand schedule. The lines on the map representing the movements of the alley gangs have the appearance of a maze but every line has received careful study.

Fig. 5. Suburban Street-Cleaning Gang; Washington, D. C.; for Cleaning Macadam and Unpaved Streets

Snow and Ice Work

While Washington is subject to frequent snow storms, very few of them are severe. The climate is such that during the greater part of the winter, the snow disappears within a few days. The streets are wide and the traffic is not often interfered with. No effort is, therefore, made to remove snow except from a few street and railway intersections, and the principal transfer points. The street

railway companies bear a large proportion of this expense.

In case of a snow fall of 2 in. or over, snow plows are sent out early in the morning to open up sidewalks throughout practically the entire white wing and machine-broom area. Later in the day, the gutters are all opened by gutter plows in practically the same territory. Crosswalks and gutters are kept clear, openings made from the crown of the streets to the gutters, and the snow is sometimes transferred to the sunny sides of the streets. The idea is to assist the snow as much as possible to melt, and run off immediately to the sewers, before the water has time to freeze.

Stables

The two stables are both new; they are fireproof even to the extent of having iron stall partitions, rolling steel doors at the larger openings, and sprinkler systems in the feed rooms. They are designed for plenty of light and air; nearly all the horses have windows above their heads. There are electric lights throughout. Both stables are plentifully supplied with washing arrangements, all equipment being washed every night.

Only a sufficient force is employed at each stable to clean the building, to feed, water, and shoe the horses, and to watch at night. The horses and harness are taken care of by the drivers.

Duties of Drivers—All drivers must be familiar with the city and trained to their work. Some must use considerable intelligence in routing their machines, and others must load their own carts and wagons. Practically, they must serve two masters, the foreman on the streets and the stable boss in the stables.

Theoretically, however, when the driver satisfies one and not the other, and the case comes to the superintendent, the driver is considered to be under the orders of the stable boss, the team and driver going to the foreman as if it were rented from the stable boss, the foreman returning the whole outfit to the stable and requesting another until satisfied. This is on the principle that the stable boss cannot be made responsible for the horses unless he controls the drivers.

Some diplomacy and good feeling on the part of both foremen and stable bosses is necessary, but very little trouble has been experienced so far, and it seems to be the only solution to a problem which promised to be difficult.

Repairs and Supplies

The foreman of repairs is responsible for the condition of all property, such as buildings, cleaning machines, wagons, carts, harness, etc. The foreman of repairs orders or manufactures all supplies and equipment; and he must correctly anticipate the needs of the division. His work is rarely stationary, for it requires inspection of scattered equipment, the supervision of odd jobs here and there, and experimenting with and perfecting apparatus.

The foreman of repairs is, therefore, furnished with an automobile or hurry-up wagon, arranged as a light motor truck, to carry tools and light supplies. He has under him a shop foreman, who has charge of and remains constantly at the repair shop, a material clerk who attends to the ordering of supplies, and a storekeeper who takes charge of the supplies when received, and distributes them.

Fig. 6. Alley Cleaning Gang; Washington, D. C., Has Approximately 1000 Alleys

Statistics of Steel Production in the United States during 1913 are summarized in Special Statistical Bulletin No. 5, issued by the American Iron & Steel Institute, which succeeds to the work so long carried on by the late James M. Swank. Steel production in the United States in 1913 exceeded all previous records, being 31,300,874 tons. The production was, however, only 50,000 tons greater than in the year 1912. Almost exactly half this steel was produced in Pennsylvania. Ohio came next with 6,700,000 tons; Indiana and Illinois combined produced nearly 5,00,000 tons. The open hearth process of steel production now far exceeds the bessemer in volume of output. Last year the bessemer steel produced amounted to 9,545,000 tons, while the open hearth steel amounted to 21,600,000. The maximum bessemer steel production was reached in 1906, when 12,275,000 tons were produced. This compares with 11,000,000 tons of open hearth steel in the same year. Since then open hearth production has been increasing at a rapid rate, while bessemer has fallen off. The production of crucible steel amounted to 121,000 tons, while 34,000 tons were made in the electric furnace. The alloy steels produced amounted to 714,000 tons. The business of steel founding has had a large development. Over 1,000,000 tons of steel castings were produced last year, which compares with 132,000 tons of steel castings in 1898. Nearly all the open hearth steel made is now made in basic furnaces. Only 1,255,000 tons of open hearth steel were made in acid furnaces. The total number of works manufacturing steel from raw materials is 304, located in 30 different states of the Union and in the District of Columbia and Panama.

A Concrete-Incased Steel Viaduct at Chicago

SYNOPSIS—This article describes the decorative treatment of a plate-girder bridge over a boulevard and park-way, in order to secure an attractive appearance. The exterior girders and columns are covered with concrete, with effective results.

※

The track-elevation work of the Baltimore & Ohio R. R., at the western section of Chicago, crosses Independence Boulevard, which is a broad thoroughfare connecting two parks and is under the jurisdiction of the West Chicago Park Commission. The boulevard is 250 ft. wide between street lines, and has two 32 ft. driveways separated by 151 ft. of parkway. The railway structure is a plate-girder viaduct, but the park commission required that it should be made of pleasing appearance, subject to its approval, and to meet this requirement the railway company adopted the plan of masking the outside girders and columns with concrete, giving the appearance of a masonry structure. The result has been very satisfactory, as may be seen from the view of the work in Fig. 1.

The park commission requires the railway to conform to the following conditions: (1) to maintain the concrete work in good condition; (2) to paint the exposed steelwork an approved light color, and repaint it when required; (3) to construct a tight floor which will prevent water, dirt and oil from dropping through.

The roadways are depressed 2 ft. at the viaduct, and the change from normal grade to the inclined approach at each end of the depression is made by a vertical curve connecting with the grades at points 80 ft. on either side of the center line. The paving is of asphalt on a 6-in. concrete base. The curbs are of granite, 6 in. thick and 2 ft. deep, except that where the cap is more than 1 ft. above the gutter the curb is 2½ ft. deep, 6 in. thick at the top and 12 in. at the bottom. The parkway beneath the bridge is covered with 6 in. of crushed limestone, bonded with screenings, and the sidewalks under the bridge extend to the curbs, the grass parking being omitted. The concrete sidewalks, curbing, paving, electric conduit and sewer work were done by the railway company in accordance with the specifications of the park commission.

The structural design was prepared under the direction of F. L. Stuart, Chief Engineer, and W. S. Bouton, Bridge Engineer, of the Baltimore & Ohio R.R. The design of the concrete covering was prepared by F. E. Lockwood, architect, of Chicago. The steel erection and concrete work were done by the railway company, being in charge of L. G. Curtis, District Engineer. The design and construction were under the general supervision of A. C. Schrader, Chief Engineer of the West Chicago Park Commission.

Steel Structure

The viaduct is a four-track structure with nine spans. There are two driveway spans 35 ft. c. to c. of columns, separated by five spans of about 25 ft. 7 in., while the two end spans are 30 ft. at the west end and 21 ft. at the east end. The headway is 13 ft. at the roadways (which are depressed 2 ft. at the crossing), 8½ ft. at the center to 11 ft. at the sides of the central parkway, and 10 to 11 ft. at the sidewalks (there being a slope of 1 ft. from the abutment to the curb.)

Fig. 1. Concrete-Incased Plate Girder Viaduct across Independence Boulevard, Chicago, Baltimore & Ohio R.R.

Each of the eight bents has five columns, connected at their upper ends by latticed struts, as shown in Fig. 2. In six of the bents each column is composed of a pair of 15-in. channels (with the flanges outward) and a 12-in. web-plate attached to the backs of the channels by four angles 4×3½ in. The third bent from each end, however, carries an expansion point, the structure being thus divided into three sections. In these two bents, each column is composed of two parallel 15-in. web-plates, with four flanges 1/2 in. on each side, and with diagonal lacing bars over the outer angles.

The bents carry five lines of 41½-in. plate girders, the girder depth being the same throughout and extra strength in the longer spans being secured by heavier

webs and flange angles. The webs of the outer girders have holes for short rods to bond with the concrete covering. The floor system consists of transverse 15-in. I-beams 21 in. c. to c., these being placed just above the bottom chords and secured to the girder webs by angle connection-plates. At the middle and end of each span are triangular brackets or gusset plates riveted to the girders and to the top of the floor-beams.

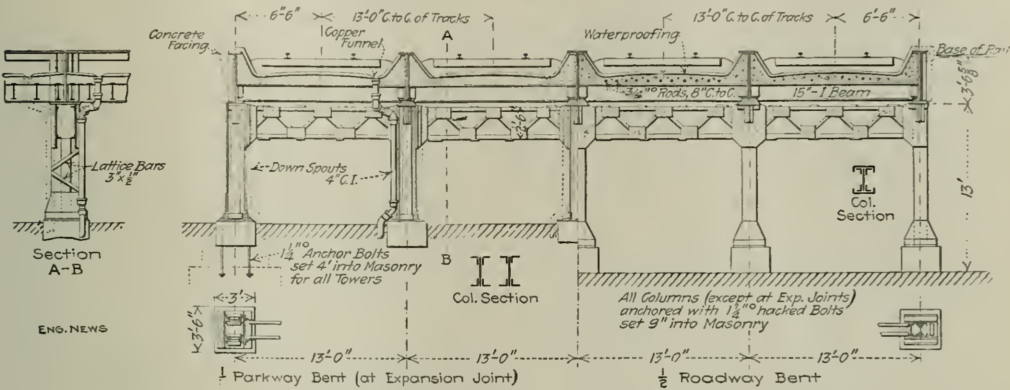

FIG. 2. CROSS-SECTION OF FOUR-TRACK VIADUCT AT CHICAGO; BALTIMORE & OHIO R.R.

CONCRETE DECK—Upon the steel floor framing is a reinforced-concrete deck or slab, the concrete being carried up against the girders so as to form a trough for each track. This deck is of 1 : 2 : 4 concrete, reinforced with 3/4-in. transverse bars spaced 8 in. c. to c. It is 8 in. thick at the middle and 7 in. at the sides, and drains longitudinally to 4-in. downspouts at the third bent from each end. On the concrete is a waterproofing course consisting of three layers of burlap mopped with hot asphalt, and this is protected by a 3-in. layer of concrete composed of cement and limestone screenings (1 : 2½). A bed of stone ballast is laid, with ordinary track construction, the ballast being about 6 in. deep under the ties, so that the base of rail is about 12 in. below the top of the concrete facing on the girders.

ABUTMENTS—The abutments are made with vertical instead of battered faces and without the usual coping at the bridge-seat, in order to conform to the architectural treatment of the concrete facing of the bridge. They are of 1 : 3 : 5 concrete, except that a 1 : 2 : 4 mixture is employed for the bridge seats.

CONCRETE FACING

In the architectural design, the columns and girders on each side of the structure are incased or masked with concrete as noted above. The two roadway spans are made distinctive by heavy columns or piers, by arched lines for the span, and by a simple decorative treatment at the piers and center of span. The bottom of the arch has a fillet of 2-ft. radius at each end, and its center has a rise of 15 in. above the fillets. The top of the arch has a deep coping with a central medallion, these parts projecting about 4 in. from the face, so as to produce an effective appearance due to light and shadow. The concrete columns or piers of these spans project about 16 in. beyond the face of the arch, with sloping buttresses projecting about 3 ft. beyond the main portion. These buttressed columns are carried up higher than the top of the arch, and are finished with concrete medallions projecting 3 in. from the face.

The main portions of the columns are reinforced with 3/4-in. vertical round rods at the corners, wrapped with wire netting. The buttresses are reinforced with 3/4-in rods at the corners, parallel with the slope of the face, and tied into the column with 3/8-in. stirrups. The steel girders are wrapped with wire netting of No. 23 gage, triangular mesh, to hold the concrete and prevent expansion and contraction cracks. Parts of this work are shown in Fig. 3.

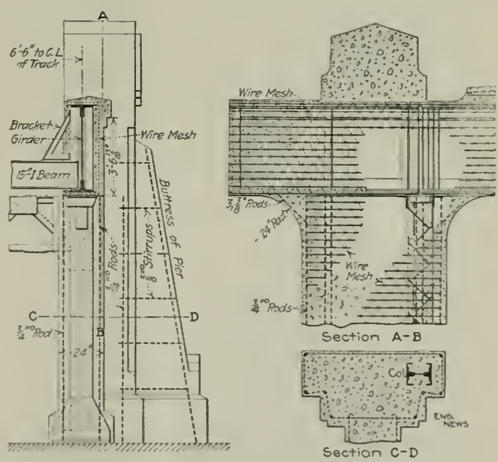

FIG. 3. CONCRETE CASING FOR GIRDERS AND COLUMNS OF THE 32-FT. ROADWAY SPANS OF THE VIADUCT OVER INDEPENDENCE BOULEVARD, CHICAGO

The shorter spans have 2-ft. fillets at the junction with columns and a very small rise (about 3 in.) above this. The coping for these spans is the same as for the longer spans, but is carried level across the bridge. The concrete casing of the steel columns is 2 ft. square and unornamented. At the corners are vertical 3/4-in. rods, with

[illegible] wrapped around them, and the fillets are also reinforced with bars placed at 45°. The corners and edges of all parts of the concrete work have a $\frac{3}{4}$-in. bevel.

The concrete used in the columns and arches was a 1:2 mixture of cement and crushed limestone (from $\frac{1}{2}$ in. to dust), no sand being used. Special care was taken to see that all concrete was of the same proportions and consistency, so as to maintain a uniform color throughout. The forms were of dressed lumber. The forms for the concrete covering of the girders were partly hung from the steelwork of the bridge and partly supported from the ground by struts and braces.

The concrete for all columns was placed before any concreting was done on the arches. The larger columns were poured to the top in one operation, a ledge being left at the junction with the arch fillet. The smaller columns were poured to the bottom of the fillets of the [illegible] arches or girders. The roadway arches were poured separately, as were the sidewalk spans and the [illegible] spans next to the roadway. The intermediate section of three spans was poured at one time, with an expansion joint at each end, where the expansion joints in the steelwork occur. The concrete was spouted directly into the forms from a mixer mounted on a flat car on the railway. No special facing was used in placing the concrete, a good surface being obtained by thoroughly spading the concrete next to the forms. The use of a small size of aggregate gave a fine texture for the surface, very little difficulty being experienced with pockets or hollows in face.

After the forms were removed and the concrete had seasoned and dried out for a few days, the lips and ridges due to the forms were chipped or filed off with a chisel, coarse file or rasp. The surface was then wetted and rubbed with a coarse carborundum brick until the surface was fairly smooth, a very thin wash of cement and sand being then applied and left to dry. The final rubbing was done with a fine carborundum brick until all the cement wash had disappeared and the surface was smooth and even. All concrete was treated in this manner, including the faces of the abutments. This treatment gives a [illegible] white surface of very light color.

The decorative treatment in this case is based upon [illegible] parts in bold relief, to give a pleasing appearance due to the light and shadow effect. With this is combined [illegible] of the surfaces. In another [illegible] bridge in Chicago with somewhat similar concrete [illegible] the surface is [illegible] [illegible] but the results were not very satisfactory. We pointed out at the time (ENGINEERING NEWS, Sept. [illegible], [illegible]) that better results might be expected by relieving the flat surfaces by outline and shadow rather than by the use of color, and this view is supported by the appearance of the bridge described above.

[illegible] The same [illegible] work of the Baltimore & Ohio R.R. [illegible] and the bridges are [illegible] with concrete in the way described above, but with less elaborate design. The girders [illegible] concrete girders with [illegible] on the faces and a [illegible] coping. The columns are not [illegible]. These bridges have [illegible] of the columns and, with transverse [illegible] the columns carrying longitudinal I-beams which support the [illegible] deck.

Spheroidal Gas-Holder Tanks

By PAUL SEUROT*

[Author's Note—This article refers to an illustrated note "Spheroidal-Tank Gas-Holders, a Modern German Type," published in ENGINEERING NEWS, of June 25, 1914, p. 1418. The remarks on design given by the author are based on notes compiled some years ago from the reports of "La Societe Technique du Gaz en France," 37 Congres, June 1910.]

The usual formula giving the thickness e of the plating of a gas-holder tank is:

$$e = \frac{HD}{2KS}$$

in which H is the height of the tank, D its diameter, K the ratio of the strength of a riveted section to the strength of the solid section, S the unit-stress.

The intention of the designers of the spheroidal tank, the Maschinenfabrik Augsburg-Nurnberg, is to replace the straight vertical wall of the tank, subject to unequal stresses and necessarily very thick, by a curved and flexible wall stressed equally at all points. This curve follows exactly the natural curvature of a drop of water or of a thin rubber-silk bag filled with water, suspended by a string and resting on a flat unyielding base (see Fig. 1 and Fig. 2); this bag and its contents then take such a shape or position of equilibrium that there is no shear in the shell at any point, the stress being purely tensile.

As pointed out in the article in ENGINEERING NEWS, above referred to, the tank cannot be a closed figure and the meridian tension must be counteracted by vertical struts. This is shown in Fig. 3. The

FIG 1

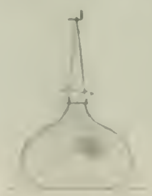

FIG 2

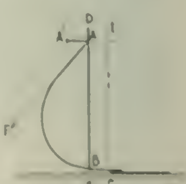

FIG 3

resultant force at A is tangential and acts along line AF. This force is resisted by a [illegible] horizontal built beam AA', and by the vertical struts DAB, which are connected together by X-braces.

The vertical struts are carried on foundation blocks K through the tank plating. The cylindrical volume of water within surface H is supported directly by the bottom plating and foundation. The volume comprised between H' and the shell produces a downward pressure which is carried through K onto the foundations.

To draw the curve of the shell, let us assume the problem solved and let AB, Fig. 3, represent the curve which is supposed to resist equal tensile stresses at all points; let us take a [illegible] metal [illegible] on the circumference of the spheroid, and let us divide the curve into a certain number of equal parts; in the present example, there are 15 divisions, 1.10 m. long each. At the center of gravity of each of these divisions, and normally, let us draw the water pressure, calculated for each point by multiplying the area of the section (its width by its length) by the

*[illegible] Engineer, Jacobs & Davies, Inc., Montreal, Que.

height of its center of gravity below the top surface. Drawing these forces one after the other, parallel to their direction and proportionately to their value, we get a polygon of forces, Fig. 4, whose closing line RR' is parallel to, and (measured by scale) equal to, the resultant RR' of the several pressures. The lines RO and $R'O$ parallel to the two reactions at the end of the curve give the value of the tensile stresses on the base-plating and at point A.

If we join the intersection of these reactions, in Fig. 4, to the several points of the polygon, we obtain the value and direction of the resultants of all the tensile stresses at each point in the shell. All these resultants must be equal, since the curve is supposed to be such that all the tensile stresses are alike. Therefore, *these lines must be the radii of a circle whose center is the intersection of the reactions,* and passing through the several points of the polygon. In other words, we should be able to inscribe the force polygon within this circle.

If now we draw the equilibrium polygon by laying, at each point of the curve, lines parallel to the rays of the force diagram, the sides of the equilibrium polygon will be tangent to the curve of the shell, and if we started at the lowest point the last side should pass at the top through point A.

In practice, the lower and higher points being given, it is customary to draw a trial curve, applying the hydrostatic pressures at each division. The force diagram corresponding to these pressures being drawn, it should be possible to inscribe it in a circumference if the original curve was correct. A few trials may be necessary to obtain the proper curve.

The weight of a tank designed along these lines will be about two-thirds of the weight of a vertical-side tank for the same unit-stress.

For instance, for a tank 13m. high and 65m. in diameter, with a unit-stress of 10 kg. per sq.mm., the thickness of the lower plating should be, in a cylindrical tank,

$$e = \frac{65 \times 13}{2 \times 10} = 12\ mm.$$

The thickness at the top would be from 6 to 7 mm. In a spheroidal tank, the thickness e would be constant and equal to:

$$e = \frac{62{,}100\ kg.}{950 \times 10} = 6.5\ mm.$$

In practice, a uniform thickness of 8 mm. would probably be adopted.

The above conditions obtain when the tank is full. When the tank is being filled, the tensile stresses induced in the wall are not equal. In order to avoid any deformation of the shell during the filling operation, the shell is connected to the vertical uprights by means of latticed girders (Fig. 6). The rivets connecting the latter to the shell cease to be under any stress when the tank is full, at which time the latticed girders could be left out altogether.

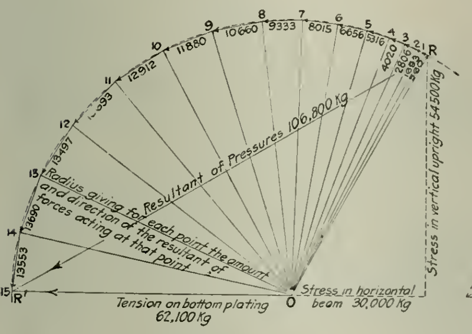

FIG. 4

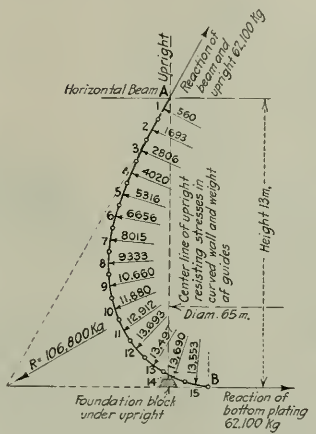

FIG. 5

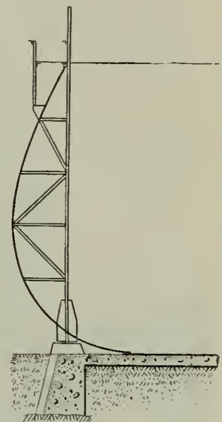

FIG. 6

In the case taken here as an example, the water pressures have been determined as follows:

No. of points	Development of skin, m.	Length of skin, m.	Area, sq.m.	Head, m.	Pressure, kg.
1	1.020	1.100	1.122	0.500	560
2	1.040	do	1.144	1.480	1,693
3	1.050	do	1.155	2.430	2,806
..	.....	.....	.....	.....	.....
..	.....	.....	.....	.....	.....
14	0.980	do	1.078	12.700	13,690
15	0.950	do	1.045	12.970	13,553

The Cable Lift Drawbridge of the Pennsylvania Lines over the south branch of the Chicago River is now nearly completed. It is a double-track bridge crossing the river on a skew of about 45° and having a through-truss lift span 272 ft. 10 in. long. The span weighs about 1500 tons, including machinery, etc., and this weight is carried by 64 steel cables 2¼ in. in diameter. There are 16 cables at each corner, pasing ove. 15-ft. sheaves at the top of the towers, and the 32 cables at each end are attached to a huge steel and concrete counterweight moving in guides on the rear side of the tower. The two towers are 195 ft. high to the centers of the cable sheaves, and are 53½x29½ ft. in plan. The towers were erected first, and then the span was erected in its upper portion on the cantilever system, with a fan-shaped falsework tower at each end, as in the Calumet River bridge for the same railway, described in our issue of Sept. 11, 1913.

When this bridge is completed, the old swing span adjacent to it will be removed, and a second lift bridge erected alongside the first one, thus giving the railway a four-track line into the city. The bridge was designed by Waddell & Harrington, of Kansas City, Mo., and built by the Pennsylvania Steel Co., of Steelton, Pa The design and construction were under the direction of J. C Bland, Engineer of Bridges, Pennsylvania Lines.

The Concrete Mixing Plant for Elephant Butte Dam

By L. J. Charles*

GENERAL FEATURES—The concrete mixing plant for the construction work of the Elephant Butte Dam on the Rio Grande Project of the Reclamation Service in New Mexico, is of interest, in addition to its size, because of the mechanical means developed to proportion the materials and with a minimum amount of labor.

This machinery is designed for this particular plant, of course, and would not be applicable where the output

Fig. 1. The Concrete Mixing Plant at Elephant Butte Dam

was to be small or the latter setting temporary. The conditions here, however, where the output will reach 600,000 cu.yd. or more from one fixed setting justified careful study of the design, in order to eliminate as much hand labor as possible, and this same point has been kept in mind also in the power house, sand-washing plant and other places.

Fig. 2 shows in plan the general arrangement with respect to cableways, railroad, sand-washing plant, etc. Fig. 3 shows the mixing plant and elevating facilities from the roadway. The position of the mixing plant in respect to the dam may be gathered by noting the axis of the dam in Fig. 2.

*Assistant Engineer, U. S. Reclamation Service, Elephant Butte, N. M.

The mixing-plant foundation is at Elev. 4376 and the crest of the dam will be at Elev. 4414. The "A" cableway is about over the center of the proposed roadway on top of the completed dam, which will strike the natural surface close to the sand hopper shown. The mixing plant, etc., are upstream from the dam.

In the mixing plant the three 80-ft. mixers are handled by two laborers and a plant foreman in general charge. This force can work the plant to capacity with a uniformly good output, the proportions of which are definitely known and which can be varied only by deliberate settings of the measures. The number of batches from each machine is automatically registered on tallying machines, and the combination of the number of batches and the known cubic contents of the measures gives all the data required for accurate determination of the quantity of materials used for cost-keeping purposes.

The laborer's duties consist of throwing a four-way cock through 90° to dump the mixer, and back through 90° to dump the batch and refill the measures. The plant foreman sees that materials are properly distributed, that concrete is delivered to the proper cableways, and looks after the operation of the plant in general.

PLANT DETAILS—Fig. 4 gives a general plan of the mixing-plant construction. The building is 54x40 ft. in plan, 74 ft. high, and arranged in five stories, the fifth

of which contains the screening machinery and head shafts of the various elevators.

The fourth story, comprising the bins, is 25 ft. high between floors, and is divided, the 40-ft. way, by two par-

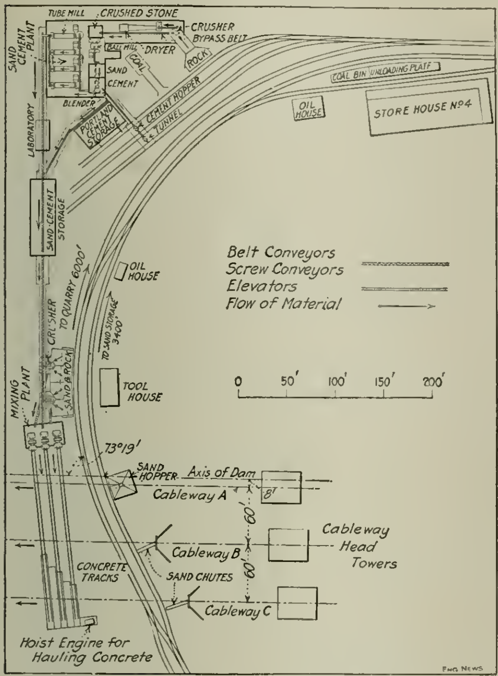

Fig. 2. Plan of Elephant Butte Mixing, Sand-Cement and Storage Plants

titions, making three compartments. The back compartment is 11½ ft. wide, with a capacity of 420 cu.yd. of rock over ½-in. diameter; the center, 7 ft. wide, holds 256 cu.yd. of sand ½-in. and smaller; and the front, 4 ft. wide, holds 103 cu.yd. of cement. The sand and rock bins are flat-bottomed. The cement bins are hopper bottomed, metal-lined, and deliver through 12x12-in. metal chutes through the vertical wall of the sand bin, and by a 15° elbow through the sand-bin floor to the cement measures.

The third floor of the building is the operating floor, containing the controlling devices for the gates, the measuring devices, which are suspended from the ceiling, the mixer-motor controllers, and the batch-tallying devices.

The second-floor houses, the three 80-cu.ft. mixers, which are arranged side by side, and dump into hoppers over the cement tracks on the ground floor. The cement tracks run approximately at right angles to the three cableways (which parallel the axis of the dam), and extend under each cableway so that material from any mixer may be delivered to any cableway independently.

Each mixer in the plant is an independent unit, having its own measuring hoppers, arranged in tandem for water, cement, sand and rock, and its individual cement bin, but draws rock and sand from a common bin through its own chutes. The mixing units are numbered from the main railroad track outward (see Fig. 2). Nos. 1 and 2 are arranged for 1 : 9 mix, and No. 3 for 1 : 6 mix. The proportions are determined by volumes.

The maximum practicable charge for one batch to an 80-cu.ft. mixer has been found to be 75 cu.ft. of loose, dry material, but for various reasons this has been reduced to a little over 66 cu.ft. The proportions for the 1 : 9 mix (adjusted by Fuller's method) are 1 : 2.9 : 6.1, requiring 7.5 cu.ft. of sand cement, 18.87 cu.ft. of sand, and 39.8 cu.ft. of rock. Weight of the batch is approximately 6600 lb.

The 1 : 6 mix is proportional as 1 : 1.8 : 4.2, and a batch consists of 10.7 cu.ft. of sand cement, 16.75 cu.ft. of sand, and 39.1 cu.ft. of rock. Both batches give a resultant of about 1.63 cu.yd. of mixed concrete. These proportions are adjusted from time to time as the material varies.

It is not planned to operate more than two mixing units at one time, but since each batch weighs over three tons, and each mixer can turn out 30 batches an hour easily, at least 180 tons of material must be handled per hour, and accurately measured as used.

Figs. 5 and 6 show the details of the sand and rock measures used on all three units. Measures similar to these have been used for sand and rock on the Pathfinder dam in Wyoming, and the Strawberry Valley project in Utah—although in both cases they were much smaller and were manually operated. These measures for the 1 : 9 mix can be adjusted by the telescoping attachment in the case of the rock between limits of 41.08 and 53.65 cu.ft. and in the case of the sand between 18.33 and 23.68 cu.ft. The No. 3 sand hopper is reduced by an internal bushing, and its capacity can be varied between 16.18 and 21.53 cu.ft.

Fig. 7 shows the design for the cement measures as originally installed. The knife edges of the segmental gates, upon which their tightness depends, were quickly

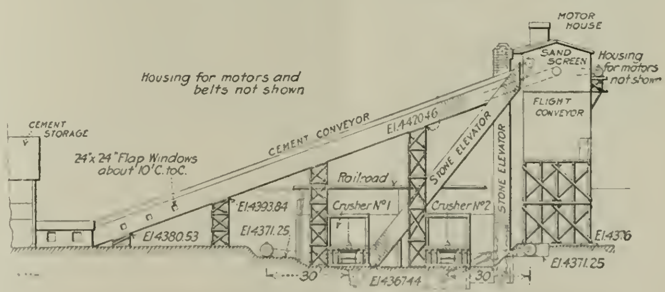

Fig. 3. General Elevation of Mixing, Crushing and Elevating Plants

ruined by catching fragments of hard material (broken pebbles, etc.) between the gate and the chute. Cement under the 28-ft. head acts in some respects like water, but has all the bad arching tendencies of sand when the flow is once arrested. Under the head mentioned a leak of knife-edge or pin-hole size will quickly waste a large

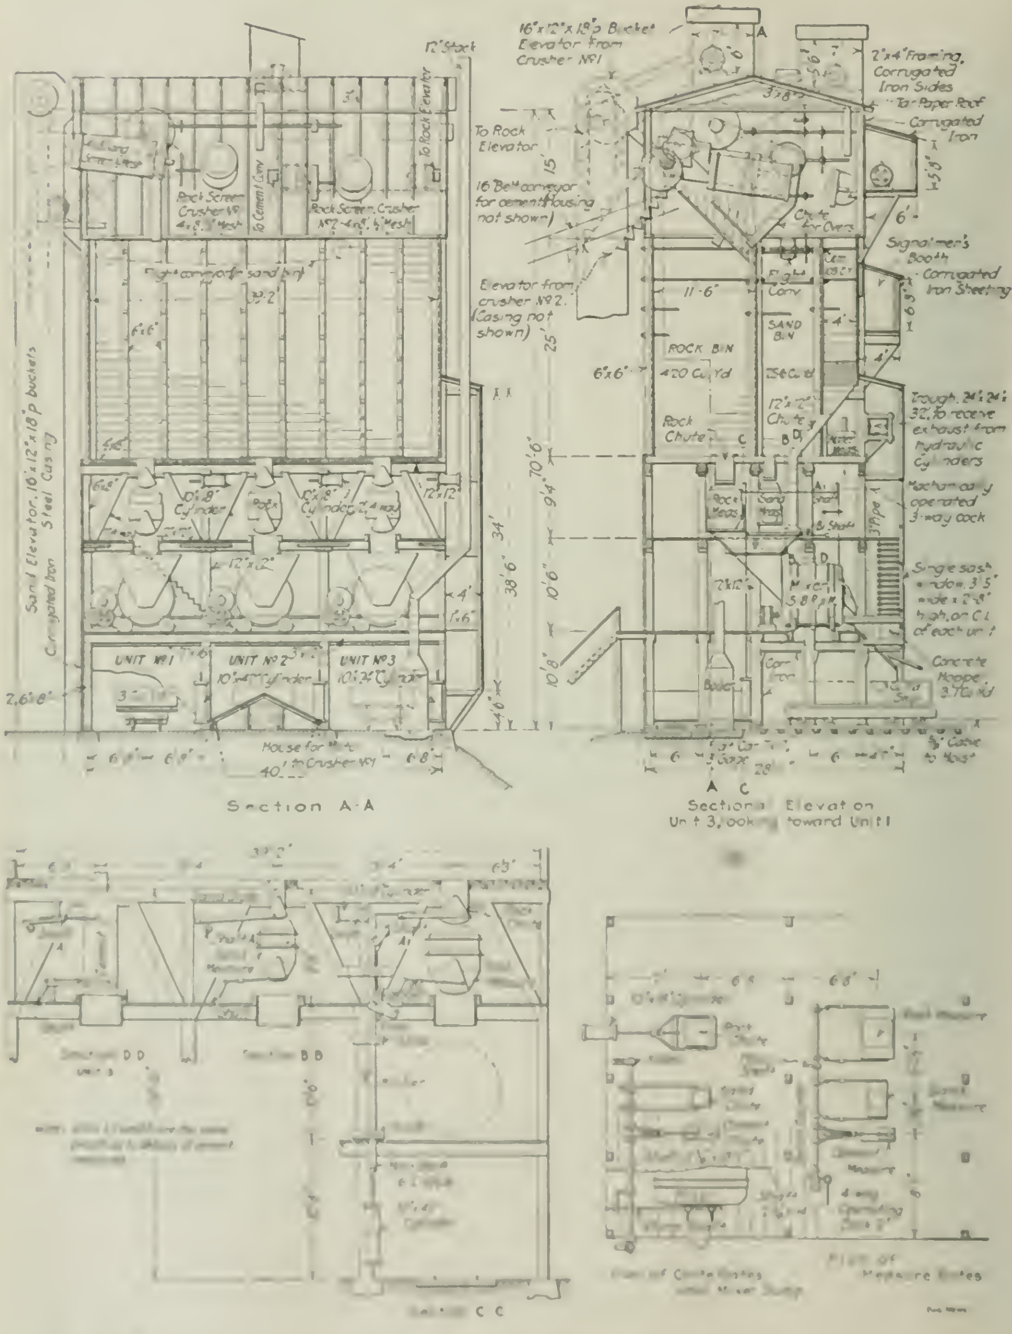

FIG. [illegible]. ARRANGEMENT OF MACHINERY IN MIXING PLANT, ELEPHANT BUTTE DAM

amount of material. The arching action has been overcome by introducing a jet of compressed air at the junction of the bin with the 12x12-in. chute (see Fig. 4). The introduction of air is controlled by a whistle valve, which is opened for an instant by the operator if an arch has formed.

Attempts were made to improve the segmental gates by hinging them eccentrically, and by replacing them with slide gates operating through the sides of the measures. It was found impracticable to pack the slide-gate slots so that they did not leak externally, without lifting them from their seats and causing internal leaks.

The original measures were finally discarded; Figs. 8 and 9 show the design of those now in use. The gates are slide gates operating over ports in the gate seats and sliding entirely within the measure. The inclined gate in Fig. 8 has been milled out ¼ in. deep, except for an inch lap around the seat, so that the gate becomes self-cleaning, and the gate guides have been removed as unnecessary. Before the gate was milled it showed a tendency to ride over the cement left on the seat, gradually developing leaks. Ample armholes have been introduced to aid in removing pebbles, etc., which are caught at the acute angle. The 2x4-in. openings covered by loose canvas diaphragms, are indicators to show when the measures are full. The 1¼-in. pipe is a vent for the relief of air compressed in the measures by the falling cement.

In the design of the operating mechanism there was the choice of water, compressed air, and electricity as motive power. Water was decided upon as the easiest controlled, slowest and steadiest in operation, while the exhaust could be used in the mix, thus getting work out of the water that would otherwise be wasted.

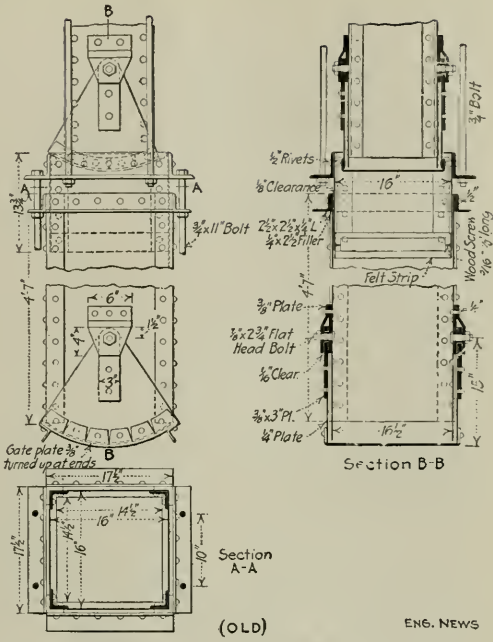

Fig. 7. Old Cement Measure

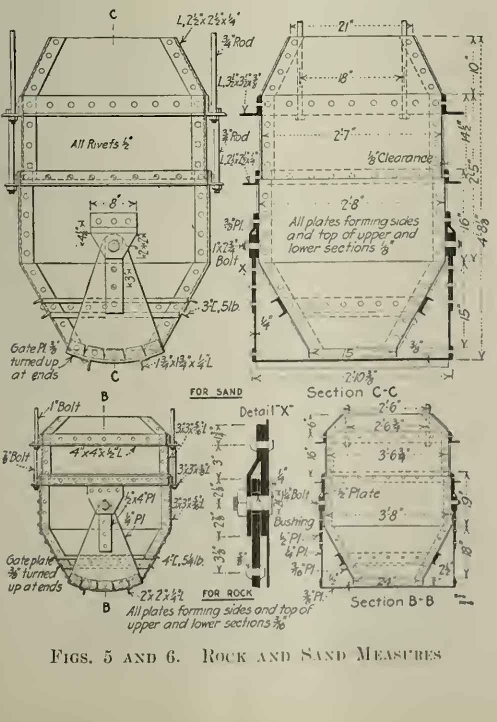


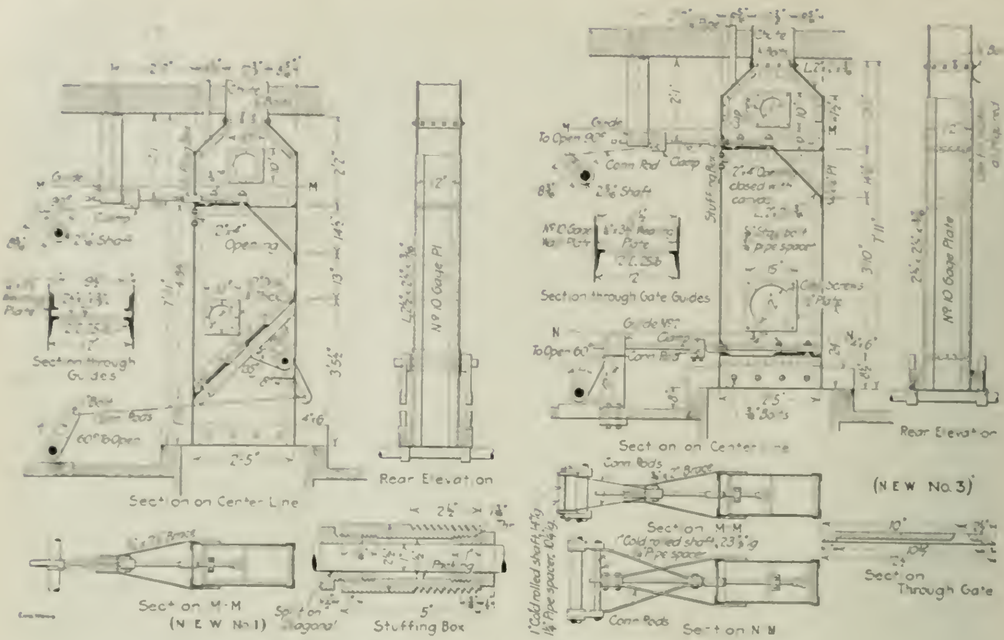
Figs. 5 and 6. Rock and Sand Measures

No data could be found upon which to base the cylinder sizes for the installation, and the following assumptions were made in the design: efficiency of the apparatus, 30%; power required to move a segmental gate, equal to the coefficient of friction of rock on steel times the weight of a column of rock 27 ft. high, and of a cross-sectional area equal to that of the opening to be cut off. The wedging of rock in the gate was allowed for by clearance of the gate below the chute. As the worst case would be that of the rock-chute gate, which if blocked would lock the entire mechanism, this was designed with a separate cylinder of its own, 10 in. in diameter, and 18-in. stroke. All the other chute and mixer gates, also the measured water dump and mixer dump, are operated by one cylinder of 42-in. stroke, 10 in. diameter. Separate cylinders for each set of gates were considered at one time, but the lack of data upon which to proportion their sizes and the difficulties of interlocking their movements led to the two-cylinder plan.

In the design of future plants, it would be advisable to make the diameter of the auxiliary cylinder larger than that of the main cylinder, as it is necessary that the rock-chute gate be closed before the main cylinder begins to open the measure gates to avoid bypassing. This difficulty occurs with this plant at times, but is obviated by throttling the flow of water to the main cylinder, so that the main piston rod moves slower than the auxiliary one. An increase in the size of the rock-chute cylinder, however, would be more logical and a better solution.

The static head of water available for power varies between 128 and 151 ft., according to the level of the water in the main-plant supply tank from which it is drawn. With heads greater than these, provision for the relief of water-hammer should be made.

Fig. 4 shows the operating-mechanism layout as in-



FIGS. 8 AND 9. NEW CEMENT MEASURES, ELEPHANT BUTTE PLANT

stalled. The piston rod of the 42-in. cylinder is extended through two floors by means of a channel extension which carries lugs to engage "kickers" on the various shafts to be operated, which are in turn connected to the various gates by crank arms and connecting-rods.

The "kickers" are built up of plates slotted out to engage the lugs on the plunger. Each kicker has an angle-iron wing upon which the plunger lug slides after the movement of the kicker is complete, thus introducing a time element between the closing of one set of gates and the opening of another.

Fig. 4 shows the mechanism at the mid-stroke point of the piston, with the A_1 kicker ready to engage on the up-stroke, and the B kicker half rotated. The B kicker operates all the measure gates, the [illegible] chute gates, the mixer [illegible], and the water measure three-way valve. The operation of the rock-chute gate cylinder is controlled by the G kicker, which rotates a three-way valve.

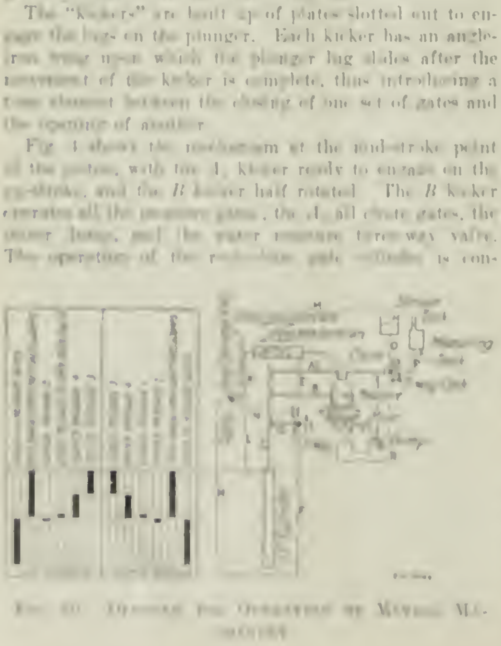


FIG. 10. DIAGRAM FOR OPERATION OF MIXING MACHINES

Fig. 10 shows diagrammatically the operation of the mechanism. Starting with the piston of the 42-in. cylinder at rest at the bottom of its stroke, and a charge in the mixer being mixed, the measure gates are open and the measures empty. The operator throws the handle of the four-way valve 90°, admitting water from the main supply through the pipe H to the bottom of the 42-in. cylinder, and through F as far as the three-way valve, which is closed. The plunger C begins to rise, the cylinder exhausting through L, the four-way valve and M to the storage tank. A plunger pin on C starts rotating the B shaft by means of its kicker, and closes the measure gates. This closure is completed just before the half stroke, and a second pin engages the G kicker, closes Passage 2, through which the forward end of the 18-in. cylinder exhausted during the cycle previous, and opens Passage 1, allowing water from the main supply to pass through F to the forward end of the 18-in. cylinder. This rotation of G is completed just over the half stroke, when a third pin engages the A_1 kicker and starts opening the sand and cement chute gates as the small cylinder opens the rock-chute gate. The small cylinder on this stroke exhausts through K, the four-way and M to the storage tank.

The A_1 shaft as it rotates dumps the mixer and rotates the three-way valve, closes Passage 4, through which the measuring tank had delivered its measured charge of water to the mixer through pipes P and R. The closure of this passage is completed at the three-quarters point of the upstroke, and the opening of Passage 3 begins, which admits water from the storage tank to fill the measuring tank through pipes O and P. The time required to [illegible] the latter is the longest period in the cycle, and

depends, of course, on the consistency of the batch. The water levels in both tanks equalize. The details of the adjustment device in the measuring tank, and also the piping layout, are shown by Fig. 11.

Referring again to Fig. 10, the upward travel of the plunger C having been completed, the piston of the 42-in. cylinder comes to rest against the cylinder head. The mixer is dumped, and the measures are all filling. As soon as this is completed, which takes only an instant, the operator throws the four-way back 90° to its original position. This admits water through L to the large cylinder, which exhausts through H and M to the storage, and through K to the short cylinder, which exhausts through E, F, H and M to the storage.

The falling plunger C begins to revolve the A_1 shaft, whose kicker is engaged closing the sand and cement-chute gates, also the mixer dump, and the piston of the 18-in. cylinder moves to the right to close the rock-chute gates. The rotation of A_1 closes Passage 3, which is completed on the half stroke, dumping the water charge to the mixer. Just before the half stroke G is engaged, closing Passage 1, opening Passage 2, and changing the path of the exhaust of the 18-in. cylinder from E, F, H, four-way, M, to E, N, M, direct to the storage tank. (This is done to close Passage 1 which controls the opening of the rock-chute gate on the upstroke.) The closure of the chute gates and mixer dump by the revolution of A_1 is completed on the half stroke down, and kicker B is engaged opening the measure gates and dumping the contents of the measures into the mixer, which operation is completed by the time the piston strikes the lower head of the cylinder.

It will be noted that the water charge starts to the mixer on the quarter stroke down, when the mixer dump is only half closed, but the slow opening of Passage 4 retards the flow, and no water reaches the mixer until the dump is well raised. The water is in the mixer about three revolutions of the mixer before the aggregate arrives, forming a cushion for the impact of the 3-ton charge, and saves wear and breakage of the mixer vanes. It also washes the mixer, removes the cement left by the previous charge, and prevents any gumming up of the mixer with partially moistened cement. The mechanism can be stopped at any point of the stroke, and locked there, by turning the four-way valve to the neutral point. The exhaust water all goes to the storage tank, and finally into the concrete. The storage is fitted with a float-valve supply and overflow, but as a general thing these do not come into use.

The plant was completed and concreting started on the dam in June, 1913, and has continued without delay. One cableway only has been available, and one mixing unit has been operated at about two-thirds capacity. On account of the excavation for foundations being carried on for a new section of the dam while concreting of the present block is in progress and because of the incomplete development of the quarries, it will be several months before the full capacity of the mixing plant can be realized. Judging from the work already done the output and efficiency of the plant will be fully up to expectations.

Personnel

Under the writer's supervision the preliminary plans, and many of the details of the operating machinery were prepared by Assistant Engineer Chas. A. Bissell, while Assistant Engineer Julian Hinds completed the detailing, and designed all the changes mentioned. The machine work and installation was done by Government forces, under W. C. Beatty, Master Mechanic. The Elephant Butte Dam is being constructed under the general supervision of L. C. Hill, Consulting Engineer, with E. H. Baldwin, Construction Engineer, in direct charge.

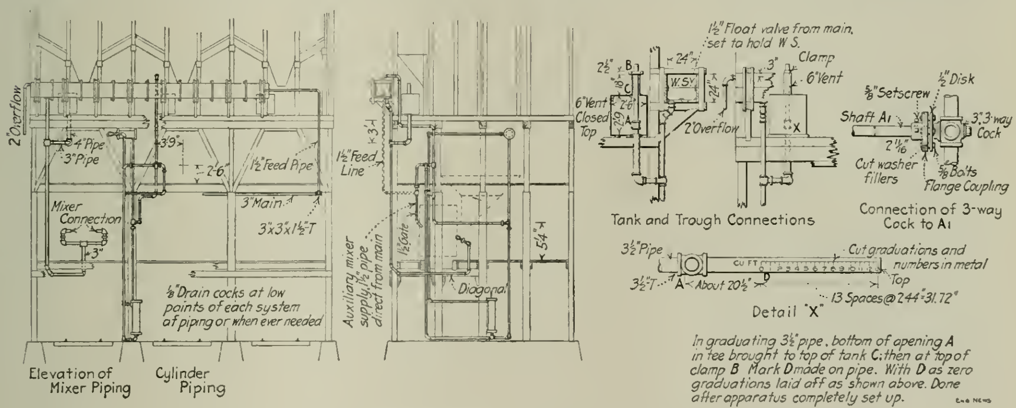

Fig. 11. Piping Arrangement, Elephant Butte Mixing Plant

Some Lessons from the Flood Failures of California Highway Bridges—The lesson taught by the failure of several long span steel bridges during the recent floods in some parts of California was a very valuable one to the counties. Many of the bridge failures were due to faulty pile foundations and consequent settling of piers; others were due to improperly designed abutments; but the principal and most important lesson taught was the urgent necessity for proper protection of the river banks to prevent continued erosion. On every river in Division No. 5 the erosion of the banks from the 1911 floods is the one big problem, and this problem should be solved before the acceptance of bridges menaced by this danger, for it may easily happen that a 700-ft. bridge accepted today may be an isolated structure tomorrow, and the expense of all the additional spans necessary to bridge this gap made by the flood waters would have to be borne by the state. [Walter C. Honer, Division Engineer, California Highway Commission, in [illegible] July "California Highway Bulletin."]

Lining Long and Deeply Overlaid Tunnels

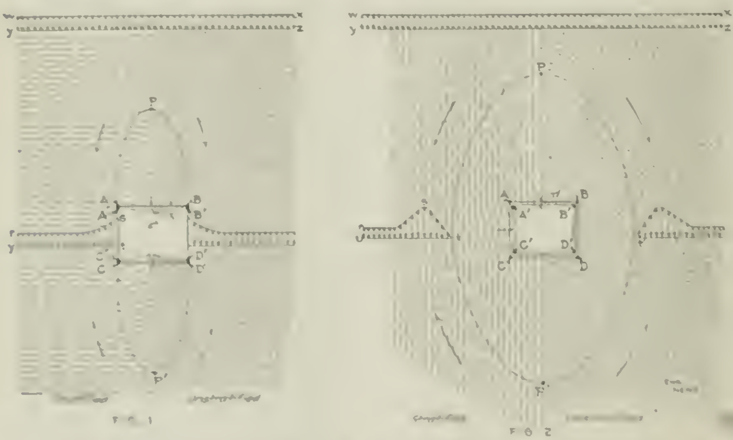
By Eugene Lauchli*

Only a few years ago, it was generally admitted that the form and thickness to give to tunnel linings was a mere matter of judgment; they were therefore proportioned according to the judgment of the engineer or designer, thus resulting very often in a waste of material, or in partial failures. The numerous observations made in tunnels, mines, shafts, bins, silos, together with laboratory experiments on the behavior of materials under compression, bending, etc., have resulted in throwing much light on this complex subject, and have shown that the designing of the lining of deeply overlaid tunnels, or of any tunnel, should be carefully considered.

Ground Pressure

It has been observed that in moderately overlaid tunnels, signs of pressure or deformation occurred first in the roof, in deeply overlaid tunnels in the sidewalls first, and then in the roof and floor. However, such phenomena have sometimes occurred in a reversed order, due to the peculiar stratification or formation of the ground, and also the crushing strength of the materials under consideration. In plastic soft materials deformation would appear under the form of crushing or bending of the tunnel roof, floor or sidewalls, while in hard and brittle materials flaking or shelling of the rock would take place.

It has also been observed that when a cave is produced in an earth or rock tunnel, or when a sand or salt bin, or a silo filled with grain would be emptied from the bottom, the void resulting from the caving, or from the material extracted, would take a vaulted shape, resembling that of a parabola. The height of the vaulted space was found independent of the depth or weight of the overlying material, but, on the other hand, was dependent on the width of the excavation and of the cohesion of the material under consideration.



Figs. 1 and 2. Diagrams Showing Pressure of Overlay in Deep Tunnels

(Fig. 1, In hard penetrating material. Fig. 2, In yielding material.)

The intensity and distribution of the ground pressure may be analyzed as follows: Let $ABCD$ (Fig. 1) represent the section of a deeply overlaid tunnel, and let $wxyz$ be the weight of the overlying mass, acting say at roof elevation of the bore. The material penetrated is assumed to be hard and solid, stratified horizontally to the left and unstratified to the right. It is evident that the load acting on the roof of the tunnel has to be transmitted to the floor, through the sidewalls AC and BD. If these are strong enough to resist the additional load, or reaction of the roof load, the stress thus borne can be illustrated by the diagram $stru$, the stress reaching its maximum value at the sidewalls, and decreasing in intensity at a distance away from same, down to a point where ru has a value equal to wy.

Under repeated blasting, and if the strength of the material penetrated is such as to allow a vertical movement of the roof and floor, the roof line AB will move down to $A'B'$, and as action and reaction are equal, the same process will be undergone by the floor line CD, to a less extent, however, as the pressure is somewhat counteracted by the weight of the material underlying the floor. A vertical movement having taken place, it is obvious that voids have been created between adjacent imaginary layers of rock above or below the roof and floor lines, and unless due provision is made to prevent further movement of the strata, the bore is liable to fill up, in the course of years, if not immediately. If, on the other hand, adequate timbering or lining is provided, further movements of the ground will be checked, and equilibrium will take place as the voids caused by the initial movement will fill up, due to successive settlements or swelling of the overlying material.

Under normal conditions, the disturbed zone will be confined within an area limited by a parabola, and the load carried by the roof of the tunnel will be that due to the weight of the materials confined within $A'PB'$.

Now let $ABCD$ (Fig. 2) represent the section of a tunnel driven through yielding material, stratified vertically to the left, and unstratified to the right. On account of the low crushing strength of the rock penetrated, and the inability of the sidewalls AC and BD to transmit to the floor the reaction of the roof load, vertical movements of the roof and floor, and horizontal movements of the sidewalls are bound to take place. The zone of disturbance will thus be spread over a large area surrounding the tunnel, and the stresses in the sidewall AC for instance, can be illustrated by the diagram [illegible]. It is evident that the load area of the parabola [illegible] has assumed different po-

*[illegible] Engineer, New York.

sitions, according to the inclination of the strata; but whatever position the axis may assume, the load to be carried by the tunnel lining, in deeply overlaid tunnels will always be a small fraction of the overlying depth.

The load acting on the roof and floor of a tunnel driven through hard and solid material will therefore be limited by the line $A'PB'$ and $C'P'D'$ (Fig. 1). The location of P above the tunnel roof will depend on the width of the bore as well as on the cohesion of the overlying material.

The load acting on the roof, floor and sidewalls of a tunnel driven through yielding materials will be limited by the line $tPt'P'$ (Fig. 2); the ground beyond these lines is supposed to have no action on the tunnel lining or timbering, provided unusual conditions such as geological faults, action of air or water on the rock, etc., will not cause large masses of ground to be set in motion, thereby causing unsymmetrical or excessive pressure.

According to the geological formation and stratification of a site considered, the following cases of loading are encountered most usually in deeply overlaid tunnels.

Case I (Fig. 3). The pressure acts vertically: there is no sign of pressure on the sidewalls. The lining should therefore be designed to carry the weight of the parabola

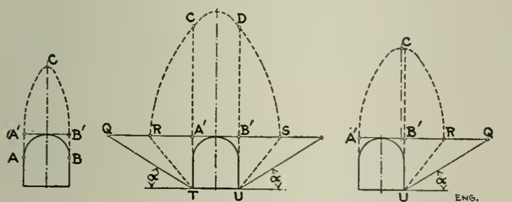


FIG. 3 FIG. 4 FIG. 5

FIGS. 3 TO 5. TYPES OF PRESSURE CONDITIONS ABOVE DEEP TUNNELS

ACB; for all practical purposes the points A and B are assumed to be in $A'$and B', located at crown arch elevation.

Case II (Fig. 4). The pressure acts vertically on the arch; signs of weakness are noticeable in the sidewalls. The arch is to be designed to carry the weight $A'CDB'$. If α represents the angle of repose of the material, it can be assumed for all practical purposes that the intersection of the line of rupture TK, with a horizontal line passing through the crown of the tunnel arch, is located at a point half-way between QA', or at R. Therefore, the sidewall $A'T$ is to resist the pressure due to the weight of the triangle $RA'T$, carrying the additional load RCA'.

Case III. (Fig. 5). The pressure is unsymmetrical to the center line of the tunnel, such a condition being caused either by the inclination of the strata or the yielding of the materials on the right-hand side of the tunnel. In this case, the arch should be designed to resist the stresses caused by the weight of $A'CB$; and the sidewalls are to resist the pressure caused by the weight of $B'RU$, supporting the additional load $B'CR$.

FORMULAS FOR GROUND PRESSURE—Several formulas that serve the purpose of determining the height of the parabola that represents the overlying weight acting on tunnel linings have been devised, but as it is beyond the scope of this paper to present and discuss all of these, the Kommerell formula only, together with a table giving results for different kinds and conditions of materials is

TABLE I. COEFFICIENTS IN FORMULA $H = \frac{100\,d}{C}$

Material	C
Pine sand, dry	1
Sand, gravel	1.5
Earth, loam, etc.	2 to 4
Marl	4 to 5
Shale	6 to 7
Harder rocks	8 to 15

TABLE II. VALUES OF H IN FORMULA $H = \frac{100\,d}{C}$

	Value of C.										
	1	1.5	2	4	5	6	7	8	10	12	15
d.	H	H	H	H	H	H	H	H	H	H	H
0.2	20	13	10	5	4	3.3	2.8	2.5	2	1.6	1.3
0.4	40	23	20	10	8	6.7	5.7	5	4	3.3	2.7
0.6	60	40	30	15	12	10	8 6	7.5	6	5	4
0.8	80	53	40	20	16	13	11	10	8	7	5
1.0	100	67	50	25	20	17	14	12	10	8	7
1 2	120	80	60	30	24	20	17	15	12	10	8
1.4	140	93	70	35	28	23	20	17	14	12	9
1.6	160	107	80	40	32	27	23	20	16	13	11
1 8	180	120	90	45	36	30	26	22	18	15	12
2.0	200	133	100	50	40	33	28	25	20	17	13
2.2	220	146	110	55	44	37	31	27	22	18	15
2 4	240	160	120	60	48	40	34	30	24	20	16
2.6	260	173	130	65	52	43	37	32	26	22	17
2 8	280	186	140	70	56	47	40	35	28	23	19
3.0	300	200	150	75	60	50	43	37	30	25	20

given here. The Kommerell formula is based on the deflection of the roof of a bore, or tunnel, and, as for the same kind of material, the deflection due to bending, increases with the width of the bore, the height of the parabola becomes a function of the tunnel width and of the kind and cohesion of the overlying material.

Let d (Figs. 1 and 2) represent the deflection observed in a tunnel roof; let C have the value given in Table I, and H be the height of an ellipse substituted with sufficient accuracy for all practical purposes to the parabola above the tunnel roof; then $H = \frac{100\,d}{C}$, the value of d and H being expressed in feet.

Table II indicates that, in a tunnel driven through sand, and with a roof deflection or settlement of 2 ft., H is equal to about 133 ft. If the material penetrated is shale, H will have an average value of 33 ft. In a deeply overlaid tunnel, C will have usually a value of 6 or more, for in such tunnels, rock only is usually encountered. However, judgment is to be exercised in selecting the proper value for C, as a roof deflection of say, 2 ft., may give H a value of 33 or 13 ft. ft. according to whether the rock penetrated is soft sandstone or limestone, or harder rocks such as granite, gneiss, etc.

TUNNEL SECTION

Having determined approximately the weight acting on a tunnel lining, the next step is to select the type of cross-section best suitable to resist the stresses borne by same. Theoretically, there is but one tunnel section that is most economical, corresponding to a given condition of loading; in actual practice, however, it would be unpractical to change the tunnel section very often; furthermore, certain clearance lines for the rolling stock and for other purposes have to be strictly observed; it is also desirable that the masonry forms and tunnel centers be made as uniform as possible. For the above reasons, it is usually the practice to design a few types of lining sections, the strength of which is determined *a priori*, adapting same, where found necessary, to conditions of loading.

In deep tunnels, and in tunnels subjected to ground pressure, it is desirable to make the roof of the bore as narrow as possible, thus making itself sustainable. In order to minimize the thickness of the arch, the thrust at the crown is reduced, by making the ratio of the arch

same in the span as small as conditions of clearance will permit. The type of arch answering best the above requirements is that nearing the parabola; but, for reasons of construction, the arch is usually made up of segments of circles. Straight lines are avoided altogether, and provision is made for future insertion of an invert, when deemed advisable.

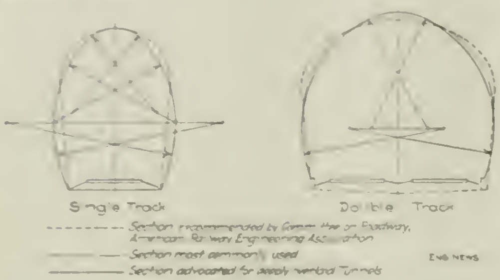

FIG. 6. TUNNEL SECTIONS FOR SINGLE AND DOUBLE TRACK

Fig. 6 shows the section recommended by the Committee on Roadway of the American Railway Engineering Association for single-track and double-track tunnels, together with that section mostly used and that section advocated by the writer for deeply overlaid tunnels. The area of the last named section is somewhat larger than the section recommended by the committee.

LINING MATERIALS

Opinions as to the kind and quality of materials best suitable to line deep tunnels, all aim toward the same results, i.e., toward material that will reach its maximum ultimate strength soon after being used, and that possesses high compressive strength, together with great resistance against action of water, heat, frost and gases from locomotives. The question of strength is obvious, for the thicker the lining, the wider the bore, and the greater the amount of excavation and masonry.

On account of the small compressive strength of brickwork, the use, in recent practice in deep tunnel work, of brick lining has been closely limited. In general, local conditions decide whether rubble or concrete masonry, or artificial masonry blocks are to be used. Rubble masonry, besides having a relatively low compressive strength, possesses the same disadvantages as concrete, i.e., the maximum strength is reached only long after being laid; and in wet sections, or in heavy pressure zones, both of these materials have proved to be rather unsatisfactory. In dry sections, and where the lining answers merely the purpose of preventing falls of rock, concrete can often be found cheaper than stone masonry.

Concrete and artificial masonry blocks are coming more and more into favor, and in general have given much satisfaction, both during and after construction. Such blocks possess the advantage of being manufactured at leisure and when used have already reached a high compressive strength. They can be placed more rapidly than dressed stone or brick masonry, and as the compressive strength of artificial or concrete blocks is more uniform than stone or brickwork, a smaller factor of safety can be used. Plain concrete blocks have been used in connection with the lining of several tunnels, and generally have given much satisfaction. Concrete blocks having an ultimate strength of 1200 to 2000 lb. per sq.in. were used extensively in lining the first bore of the Simplon tunnel. Similar blocks possessing an ultimate strength of 2500 lb. per sq.in. were used in lining the Loetschberg tunnel. The lining of the 26,683-ft. Hauenstein double-track tunnel and part of the second bore of the Simplon tunnel will consist of artificial masonry blocks possessing, when placed, 70% of a guaranteed ultimate compressive strength of 2844 lb. per sq.in. These same blocks when tested were found to have an ultimate strength of 4000 to 5000 lb. per sq.in.

Concrete blocks of the interlocking type are being used extensively in connection with the lining of the Mount Royal tunnel at Montreal and the method of erecting these blocks will undoubtedly make their use very popular in deep tunnels where a strong lining is often required soon after the excavation has been completed.

A New Portable Asphalt Mixing Plant; Catskill Water Supply Roads

A portable asphalt-mixing plant, shown in the accompanying illustration, Fig. 1, has been in use for the past two months on one of the roads built around the Ashokan reservoir by the Continental Public Works Co. for the Board of Water Supply of the City of New York. The apparatus was made by the F. D. Cummer & Son Co., Cleveland, Ohio, and consists of three units, which may be separated and loaded on flat cars in a few hours. According to W. B. Spencer, President of the Continental Public Works Co., the plant has averaged approximately 1060 sq.yd. of 2-in. bituminous top mixture per day, and has proved efficient and economical.

ASPHALT-MIXING PLANT

FIRST UNIT—The first unit consists of a drum sand dryer, having a rated capacity of 8 tons per hr., but with a tested capacity of 11 tons, with sand carrying 7% moisture and heated to 450° F., a two-shaft batch mixer of 5 cu.ft. capacity; a sand-bin of $5\frac{1}{2}$ tons capacity, with a rotary screen so arranged that sheet asphalt, asphalt binder, or asphaltic concrete may be mixed without changing the arrangement of the units; a sand measuring box on a beam scale, so arranged that each aggregate may be weighed separately or in combination, and an asphalt bucket on a double-beam scale. The whole unit is mounted on an all-steel truck (Fig. 2) with 30x12-in. front wheels and 36x12-in. rear wheels. Power is transmitted by one main shaft $2\frac{15}{16}$ in. in diameter and one main belt drive from the engine. The drum and mixer are directly connected to the main shaft.

SECOND UNIT—The second unit is the power unit, consisting of a 30-hp. locomotive type of portable boiler with a 25-hp. horizontal engine mounted on top, made by the Erie Engine Works, Erie, Penn.

THIRD UNIT—A 10-ton portable asphalt melting kettle constitutes a third unit. This unit is also mounted on an all-steel truck with steel wheels. Kettles are also made in 7-ton sizes.

The whole plant is modeled after the larger railway

FIG. 1. PORTABLE ASPHALT MIXING PLANT; ASHOKAN RESERVOIR ROADS, NEW YORK

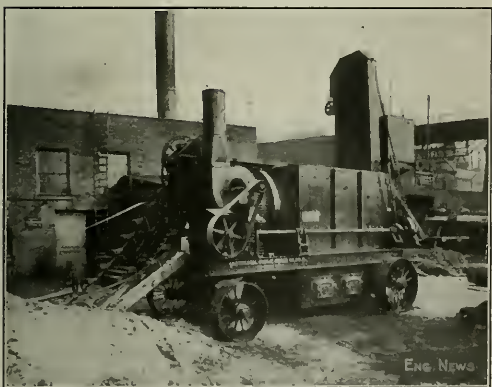

FIG. 2. MIXER UNIT, CUMMER PORTABLE ASPHALT MIXING PLANT

car mixing plant, which has been made by the same company for several years. The car plant has a capacity of 2000 sq.yd. of 2-in. bituminous top mixture per day, or about double the capacity of the portable plant.

The portable plant is designed to be hauled along the road as the work progresses. All the construction work that is necessary is to jack up the wheels of the mixer about 2 ft. to permit a wagon to be backed under it to receive the load. In Fig. 1 two standard kettle units are shown, one 10- and one 5-ton, but the trucks have been removed.

METHODS OF CONSTRUCTION; ASHOKAN ROADS

The Board of Water Supply specifications call for a pavement made of a 2-in. bituminous wearing course of 1½-in. stone with a seal coat of asphaltic cement and stone chips (stone passing ½-in. screen and retained on dust jackets), laid on a 6-in. bottom course of rolled crushed stone. The broken stone for the bituminous wearing course is heated to between 225° to 300° F.

The asphalt cement is required to be heated separately from 275° to 350° F. The mixture used contains 5 to 7½% bitumen by weight. The mixture is delivered on the road at a temperature of not less than 150° F. As soon as the wearing course is completed and rolled and the surface is clean and dry, the seal coat of hot asphalt cement is spread with squeegees or other suitable methods, at a temperature of not less than 275° F., or more than 350° F. The rate of application is between ½ and ¾ gal. per sq.yd. On this is immediately spread a uniform layer of dry stone chips, and the pavement is rerolled.

Steel Ties on Swiss Railways represent 65% of the mileage of the government railways. They are of rolled steel, of inverted trough section, with ends bent over and closed, and the ties are bent longitudinally so that the rail seats have an inclination of 1 in 20. The weight of the tie is about 160 lb. The rails are secured by clamps, and no tie-plates are used. At the rail joints, wide double-trough ties under the joint are now being used, instead of two closely spaced shoulder ties. these joint ties weigh about 276 lb. The above information is given in a recent consular report.

Rolling Asphalt Surfaces to Avoid Depressions—An English engineer, C. H. Cooper, Engineer and Surveyor of Wimbledon, has applied for a patent on a method of preventing depressions in rolling asphalt pavements, which he describes in a letter to the "Surveyor" of July 10, as follows:

In rolling asphalt it is necessary to bring the roller to a standstill for the purpose of reversing. In so doing the front rolls become stationary on the hottest, and certainly on that portion of the asphalt which can least resist their weight; the consequence is that depressions are formed in the asphalt, which should have a perfectly even surface so as to avoid the corrugations found in most pavements. In order to distribute the weight of the front rolls, and so avoid the formation of depressions, I place a sheet of iron on the asphalt—on this sheet the front rolls rest when the roller is brought to a standstill.

Field and Office

Moving Loaded Electric-Light Poles

By C. E. Drayer*

When a portion of St. Clair Ave., Cleveland, is repaved this year, both curbs will be moved back 2½ ft. between East 23rd St., and East 55th St., so that the width of pavement will be 60 ft. and uniform with that east of East 55th St. The plan to move the curbs required the Cleveland Electric Illuminating Co. to move back a line

Electric Truck in Cleveland Fitted for Moving Poles

of heavy poles a like amount. On the average, the poles are 70 ft. long, and carry four crossarms and about two dozen wires.

From East 23rd to East 40th St., the poles were moved back by hand by jacking them along cross timbers. But between East 40th and East 55th St., a 12-in. gas main, some 4 ft. in the ground, was against the poles in the [illegible]. To get the base to the new position, it was necessary to raise the poles vertically some 5 ft.

A 3½-ton electric truck, equipped with a 3-hp. motor and winch for pulling cables through underground conduits, was rigged up with derrick and backstays shown by accompanying figure. Four [illegible] channels with I-beams [illegible] along the center, were made fast to the tail of the truck at one end and bolted together at the top.

In operation, the truck backed up to the pole with the rear wheels as far from the face of the curb as the pole was to be moved back. A clamp to which the tackle was fastened was placed about the pole near the surface of the ground and a jack placed beneath the bed of the truck at the back end. When all was ready, the driver raised the pole by the motor and winch, and backed up the truck until the rear wheels struck the curb. The pole was steadied, against falling at right angles to the street, by a pike pole above and a piece of steel stuck into the pole below and fastened to the truck bed. The jack under the end of the truck was allowed to topple over during the backing movement.

*[illegible] East [illegible] St., Cleveland, Ohio.

Co-operation on Construction Work between Engineers and Contractors

By J. C. Lathrop*

During the construction of a new boiler house for the Consolidated Gas, Electric Light & Power Co., Baltimore, and after the steel frame was erected, a 3-ton jib crane so arranged that it would swing over the B. & O. siding adjacent to this plant and deliver material to the main boiler-room floor 20 ft. above this track was a decided help to all contractors, as well as to the company.

As the columns adjacent to this siding are designed to support a very large load in the future but are now carrying practically nothing, it was safe to attach the crane to one of these columns, in the manner shown on the accompanying photograph. A certain amount of the temporary covering for this side of the building was omitted until the completion of the building.

Jib Crane Put Up for a Company Job, and Later Used by Various Contractors to the Advantage of All Concerned

This crane was installed by the company for the use of the company's men while unloading parts of six Tucker stokers. There were but nine carloads of this material and it was not thought necessary to buy an elec-

*Consulting Engineer, Consolidated Gas, Electric Light & Power Co., Baltimore, Md.

FOUNDATION WORK IN THE LINCOLN MEMORIAL

tric-driven chain block for this work. A chain hoist was used for the heavier pieces and the light material was raised with a block and tackle. If the amount of work which this crane was called upon to perform had been anticipated in the beginning, it would have been a decidedly good investment to have purchased an electric chain hoist.

In addition to the stoker parts above mentioned, the contractor for the boilers used this crane in raising a large amount of minor material, the heavier parts of the boilers having been raised earlier by means of a derrick which the steel contractor had on the work. The contractor for the piping used the crane for raising all piping which went above the main boiler-room floor. The photograph shows this contractor raising a large section of 36-in. atmospheric exhaust pipe. As this work was done on the basis of cost plus a percentage, any saving was directly advantageous to the company.

The contractor for the boiler breeching unloaded all material and placed it upon the main boiler-room floor with the crane.

Numerous miscellaneous items which were to be erected in the boiler room above the main floor, such as coal chutes, minor beams, walkways, coal scales, etc., were unloaded from the cars and placed on the floor by the crane.

The above experience would indicate that better cooperation between the owners and the numerous contractors employed on a job of this magnitude would lead to better returns, for the following reasons:

First, if the owner or his engineer when asking for proposals would state what tools and facilities of that nature would be provided by the owner, it should lead to a considerable reduction in the prices quoted.

Second, the relation of the various contractors could be better controlled by the engineer in charge.

Third, a progress schedule prepared by the engineer could be held to much more closely than is usually the case, for it could be understood in the beginning that if the contractor or manufacturer was not ready to use the facilities provided by the owner at the time specified in the contract, he should forfeit the right to their use. He could then use them at night or at the discretion of the engineer. Doubtless, many unforeseen obstacles would prevent the exact working out of such a schedule and the control of these tools would necessarily be left more or less to the engineer in charge.

Sinking Cylinder Piers for the Lincoln Memorial

The accompanying view is from a recent photograph of the foundation work for the Lincoln Memorial on the banks of the Potomac River, at Washington, D. C. As described in our issue of May 7, 1914, p. 1010, this memorial to Abraham Lincoln is to be in the form of a Grecian temple and the superstructure is to be carried through the medium of a concrete substructure and a number of reinforced-concrete piers reaching down to bedrock some 40 to 50 ft. below the present surface. These piers are being sunk by the cylinder-pier method; that is, by excavating inside a weighted steel cylinder and adding upper sections to the cylinder as it sinks under the weight. After the cylinders reach rock they are filled with concrete reinforced with vertical twisted steel rods held in place by a spiral of steel.

In the view, a number of the footings may be noted. At the far left a reinforcing unit is just being dropped into an already sunk cylinder and just to the right of the spiral is shown the loading of another cylinder. In the foreground, the reinforced-concrete caps of the cylinders which have reached bottom are shown.

The work is being carried on by the Lincoln Memorial Commission with the engineering part under the direction of Col. W. W. Harts, U. S. Army. M. F. Comer & Co., Toledo, Ohio, are contractors for the substructure.

A Simple Instrument for Measuring the Deflection of Bridges and Structures, which has been quite extensively used in Europe, but until now has not been put on the American market, is called the deflectometer. This instrument consists merely of a revolving dial, about 5 in. in diameter, a pointer, a central pulley geared to the axis of the dial, and an idler pulley, which may or may not be used. There are two ways of using the instrument, either placing it on the structure, the deflections of which are to be measured, or on an adjacent rigid support. A steel tape or belt passes over one or both pulleys, and it is the movement of this tape which is magnified on the dial scale. When the instrument is placed on the structure one end of the tape is fastened rigidly below, to a buried weight or other anchor. The other end of the tape, after passing over the pulley, is attached to a weight, which is free to rise and fall. If the instrument is on a separate rigid support, the end of the tape is attached to the deflecting structure by a clamp, instead of being anchored. All movements of the tape are transmitted to a circular motion of the dial, a pin projection on which moves the pointer to ther scale reading. The pointer remains at the scale reading after the dial moves back, as it, of course, does when the load is taken off the structure. The instrument can measure the movement, vertical or horizontal, of any structure or part of a structure to 0.01 mm. The deflectometer is the invention of Wilhelm Fentzloff, Frankfort-on-Main, Germany, and is being introduced in this country by F. J. Bernard, 70 Murray St., New York City.

Rapid Rechaining for Railway Appraisal

A part of the work of valuing the railways of the United States now in progress under direction of the Interstate Commerce Commission consists in accurately measuring the length of all the railways in the United States. As the length of sidings and spur tracks as well as main tracks has to be measured, this means the measurement of lines over 350,000 miles in length.

The first tentative draft of the instructions for roadway and track field parties, issued by the Commission Apr. 23, specified that the measurement shall be done carefully and accurately with a steel tape measuring continuously along one of the nearest rails. This measurement is to be transferred to the base line, which on single-track road is central between the rails and on double-track roads is located midway between the two main tracks.

If measuring the length of the lines were all that was necessary for the valuation work, this length could be ascertained at a small fraction of the cost involved in the chaining by designing a simple odometer, merely an alloy wheel flanged to run on the rail and drawn along the track by a velocipede car or section motor car. With accurate calibration of the instrument and care in accelerating and stopping the machine, results of very high accuracy could doubtless be attained.

The survey parties, however, are required to mark all 100-ft. stations on the web or base of the rail, and the survey notes have to locate by stations and pluses all culverts, trestles, bridges, intersections of state, county, township and other lines, etc. The chaining is therefore necessary anyway. The odometer measurement, above suggested, however, might serve as a valuable check against errors of magnitude in the chaining.

A Temporary Sand-Bag Dam

In the improvement of the new Beargrass Creek channel (for an open storm-water channel) at Louisville, Ky., a sand-bag dam was built at the junction of the South Fork and Middle Fork for the purpose of diverting the flow of the creek to an intercepting sewer during construction work below this point.

The dam as first built is shown in Fig. 1, and was intended to be strong enough to stand during the lighter storms only, and to fail in storms severe enough to cause [illegible] endangering property above. During the construction work, the dam was washed out six times.

The width of the creek at the site of the dam was about 40 ft., but the dam was extended at the top to a length of about 60 ft. It had a height of about 6 ft. For the first construction, the dam had two rows of [illegible] piling driven against horizontal timbers into the bed of the creek to prevent underflow. The two rows of sheeting (which show in the view) were placed 5 ft. apart and the space between them was filled with sand bags. The sacks used for the dam were of about 2 cu.ft. capacity, but were filled [illegible], being sandy clay found near the work.

In order to obtain a dam of greater stability, some modifications were adopted upon its reconstruction. The most substantial type of dam was built of a trapezoidal section, and the sand-bags were protected by inclined timber aprons spiked to a heavy timber framework and secured at the bottom to sills set in the bed of the creek. The downstream face or apron was inclined at a slope of 1½ vertical to 1 horizontal; the upstream face was somewhat steeper. The completed dam as built in this way is shown in Fig. 2. For information we are indebted to J. H. Kimball, consulting engineer, Louisville Trust Bldg., Louisville, Ky.

Shoring Difficulties in St. Louis Sewer Construction

By [illegible]*

The Apr. 16 issue of Engineering News contained an article describing very fully the reconstructed Rocky Branch Sewer in St. Louis, Mo. Not the least of the difficulties in carrying on this work was in connection with the shoring of the trench by means of sheet piling. Both sides of the streets through which the sewer passes are built up with residences and stores, and in many places

*Consulting Engineer, [illegible], New York City.

the material excavated was of loose nature, such as wet and dry sand, as well as quicksand.

The work is near completion on the round, 14-ft. brick sewer. Steel sheet-piling is driven to a depth of 40 ft. or more by means of extension pieces; steam piledrivers on derricks having 50-ft. booms, are employed. Excavation is accomplished by a steam crane with bucket. As the earth is removed, the sheet-piling is strongly braced lengthwise and crosswise by heavy timbers.

After excavating nearly to quicksand, special precautions are necessary, not only to protect adjacent property but also to make further operations possible. Bulkheads of plank piling are built across the trench every 20 ft. or so. These are 24 ft. high and are driven about 9 ft. below subgrade. The bulkhead, 8 in. thick, is composed of bolted tongue-and-groove piles. The details of the shoring are well illustrated in Fig. 1. With such an arrangement, it is comparatively simple to keep the trench dry and proceed with the work of laying the sewer.

As the completed masonry nears one of these bulkheads, it is not feasible to pull the plank piling until the fill has been at least partly completed, as the heavy cross timbers are partly braced by the piling and must be left to support the steel piling at the sides. The expedient adopted as most practical was to cut off the bulkhead piling slightly below grade and also just below the lower wale, which allows sufficient clearance for the masonry work.

The first attempt was to cut off these piles with an ax, but this method was found to be extremely slow and difficult. Large wood chisels fitted to special pneumatic hammers were next tried but without satisfactory results. Circular saws were also considered, but were discarded as being unsafe. Then a 1¾-in. wood-boring auger, operated by a No. 13 size "Little David" compressed-air drill motor, was tried and found to be a very practical means for cutting these thick planks. This motor requires about 30 cu.ft. of free air per minute, which was furnished by a Westinghouse air-brake pump. About seven holes of this size are required to sever a pile and the time consumed in boring each of these 8-in. holes is from 20 to 25 sec. Two or three are required to cut across the pile, so that the entire time consumed in making both cuts across the trench figures ordinarily, between 1½ and 2 hr. The cutting is often in awkward locations and sometimes the tool has to be operated under water.

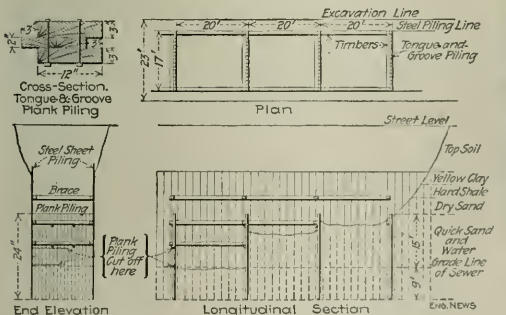

FIG. 1. SHORING AND BULKHEADS IN ST. LOUIS SEWER TRENCHES

Similar methods were employed on another part of the sewer which has been completed. There the sewer is rectangular in section to save headroom. On that section about 15 ft. of the lower part of the excavation was quicksand. Side piling, composed of 6x12-in. by 20-ft. planks, was driven down 6 ft. below subgrade and served not only as a bracing for the excavation, but also as the outside form for the concrete.

After the concrete had set, these piles had to be removed or cut off just below the street grade. As they were embedded quite deeply and were needed to prevent settlement of the adjacent ground, it was impractical to remove them, and the city permitted the contractor to leave them after cutting off the upper ends. There were about 1500 of these piles and a pneumatic wood auger was employed, as previously explained, for cutting off the piles about 10 in. below the pavement. It required from 16 to 20 sec. to bore each 6-in. hole, making the time for boring 7 holes, to cut one pile, 1¾ to 2½ min.

FIG. 2. CUTTING OFF THE TIMBER BULKHEAD PILING

(Shows the upper cut, just below the lower wale. The lower cut is hidden by the material on the floor. A small section of the sheet piling is shown at the extreme right.)

The above described work was done by the James Black Masonry & Contracting Co., of St. Louis. The writer is indebted to G. W. Winslow, of St. Louis, for most of the data contained herein, as well as the view.

A Reversible Section Liner—The "Sphinx" section liner, made by F. Weber & Co., Philadelphia, Penn., is now made in a reversible type, that is, the spacing apparatus made be made to operate either from right to left or from left to right. The 7-in. beveled arm may be set at any angle. The reversible section liner costs $1.75, or 25c. more than the single-action kind.

A Record of 65 Years' Progress in City Surveying: St. Paul, Minn.*

In 1849 when the village of St. Paul was incorporated, property ownership was based on claim lines. In 1853 the United States completed the subdivision of the territory now covered by the city, and since that time subdivision lines have been based on these township and section lines, excepting where claim lines existed.

Between the years 1885 and 1890, all of the section lines within the city limits were rerun with transit and steel tape, and all section and quarter-section corners were marked with granite monuments. At the same time all streets were resurveyed and monumented, so that a complete survey of the then existing, laid-out portion of the city's entire area was made and mapped on a scale of 100 ft. = 1 in.

All existing platting was shown on these maps with record distances, and also the resurveyed distances with monuments. These maps were called Standard maps and were made on mounted eggshell, each map covering one mile east and west and one-half mile north and south. There is a total of 118 of these maps. They were public records and were used continually by outside surveyors, real-estate men, etc., as well as by employees of the City Engineer's office.

FIG. 1. STANDARD GRANITE MONUMENT FOR STREET LINES, ST. PAUL, MINN.

As these maps became badly worn an attempt was made in 1902 and 1903 to trace them, but it was found impractical as so many of the lines had been obliterated by use and, furthermore, a great many errors had been made in the tracing and in the original platting. It was then decided to redraw them from the original notes on heavy, detail paper, trace these drawings and blueprint them; the blueprints were to be used by the public and the original drawings to be preserved.

MONUMENTS—Prior to 1901 all additions to the city were marked with wooden hubs, but since that date all block corners in new additions have been marked with iron pipe, in accordance with a state law. The additions have been laid out with reference to the section lines, and setting these pipes became the center lines of the previous street system, except where claim lines existed. As streets were improved these iron pipes were replaced by standard granite monuments (Fig. 1), either at the location of the iron or at the street intersection; now 90% of the streets are sufficiently well monumented to make the running out of a street line a simple matter. Fig. 2 shows method of locating and referencing monuments.

*From annual report of the [illegible] of Public Works [illegible], St. Paul, Minn.

As additions or rearrangements are platted and recorded in the Registry of Deeds office they are put on the Standard maps and after streets are improved they are monumented and the monuments are also shown on the Standard maps.

For a great many years a monument atlas was kept up, and it was necessary to refer to this atlas when monuments in any particular locality were required. Monuments were numbered and the number referred to the page of the monument record book on which were given the notes and ties required.

This monument record, for some reason, fell into disuse and it has also been found that the records on the Standard maps for the last few years are not complete. To remedy this a card-index monument record has been started with the intention of bringing up to date all records of monuments in the city. These cards are indexed under the street name. There are three or more intersections to each card and the cards are numbered and run consecutively on each street from the center of the city outward. These cards are also used for records of roadway widths.

The monuments themselves received no better care than the records. A great many of them were taken out or disturbed during construction work, such as grading streets, putting in sewers, and then not replaced. Some of the monuments were taken out by contractors under instructions from the street engineer because it could not be avoided, but the department was lax in not having them replaced as soon as the construction work was completed.

Specifications in all contracts for city work have the following clause:

> The contractor shall not disturb any monuments or stakes found on the line of the improvement until ordered by the engineer and shall reset any monument as directed by the engineer. A penalty of $25 may be imposed for each monument disturbed without orders and the amount deducted from the estimate.

ADDITION PLATS—All plats of additions or rearrangements of the existing platting must be submitted to the County Plat Commission for approval. This commission has jurisdiction over the arrangement of streets and alleys, their width, and their connection with existing streets and alleys, the placing of monuments, the corrections of the survey and the placing of all data on the plat necessary to retrace it in part or in whole on the ground.

FIG. 2. METHOD OF SETTING AND REFERENCING STREET MONUMENTS, ST. PAUL, MINN.

When surveys are necessary to check the accuracy of the work they are made by the City Engineer upon request of the Plat Commission when within the city limits

and by the County Surveyor when outside the city limits and within the county.

The Commission also sees to the compliance with the law regarding size of plats, quality of paper, character of drawing, form of affidavit, descriptions, dedications and acknowledgments. It is also the business of the Commission to see that a copy of the plat is made and filed in the City Engineer's office before the original is placed on record.

Hydrographic Surveying with a Four-Man Party

By B. L. Rees*

Some time ago, while the writer was in charge of some harbor work in the South for a private concern, it became necessary to take a series of off-shore soundings, where the method of locating soundings from two transit stations on shore was the only one applicable. The available party consisted of only one assistant engineer, a transitman, a laborer for a boatman, and the writer as the second transitman.

The results were very satisfactory, and the work was done rapidly. A party of four is believed to be the smallest possible for such work, and as some of the methods and equipment employed were unique but practical, a detailed description of both is here given.

Special Sounding Line—The usual cotton-cord sounding line was not used because of its variable length. A brass "jack" chain was substituted. The links of this chain are in the form of a figure 8 with one half of the link bent at right angles to the other. This type of chain does not kink readily and is easily handled, while it has the advantage of constant length, thus avoiding a variable correction.

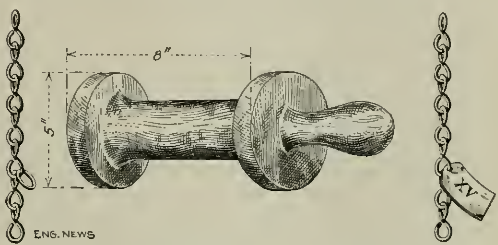
A good-sized chain for sounding purposes will run from 5 to 8 ft. to 1 lb. The foot marks were galvanized-iron rings about ½ in. in diameter, although brass is preferable when brass rings can be obtained. The 5-ft. marks were small strips of rawhide into which Roman numerals were burned with an iron. Circular brass tags about ⅝ in. diameter are preferable when obtainable. The chain was not used for casting, but the writer can see no objection to the use of such a sounding line when casting is necessary.

Tide Gage—The tidal range averaged about 8 ft. A tide gage was set where it could be readily observed by one of the instrumentmen while the soundings were being taken, although the work was generally done about slack low water.

Sounding Boat and Crew—An ordinary flat-bottom row boat, locally called a "bateau," with a single oarsman, was used. The leadsman did his own recording on manila cards 6x10 in., made fast by thumb tacks to the bottom of a shallow box which rested on the stern seat in front of him, while he was sounding. These cards were properly ruled and the lines numbered consecutively. As soon as the leadsman had completed his work, his records of soundings, necessarily wet and soiled, were immediately transferred to one of the transit books, checked, and the cards destroyed.

Whistle Signals—Next to the sounding chain, the most important item of the leadsman's equipment was a standard police whistle. With this whistle held in his mouth, he blew a signal whenever a sounding was taken. This "whistle method" replaced the usual method of timing soundings. The writer believes this whistle method has many obvious advantages over the time method, particularly since soundings can then be taken when possible—a very decided advantage in rough or flowing water. Where the leadsman is so far from the instruments that such a whistle is impractical, the body of water will necessarily be of a size requiring a power-boat and a flag or other flash signal will answer the same purpose. An extra or fifth man might be required in such a case.

Field Methods—The leadsman stood in the stern of the "bateau" facing back and had the box of record cards



Chain and Reel Used in Four-Man Sounding

before him on the seat. When ready to take a sounding, he suspended the lead-chain over the side of the boat toward the instrumentmen. Both instruments were then sighted to the chain at the water surface, and the alidades turned to follow the chain as the leadsman moved it slowly around and off the stern.

As the lead touched bottom, the leadsman blew the whistle and both instrument alidades were stopped at that position. He blew once for each sounding except the fifth, when two blasts were given; and in this manner the three men had a check, which was signaled back to the leadsman in the boat by the instrumentmen using the regular arm signals.

While the leadsman was recording his soundings and moving to another position, the instrumentmen read and recorded the horizontal angles and observed the tide gage.

The advantages of this method were: the leadsman gave the signal promptly and avoided the delay of telling a second man to signal; he took the soundings to the best advantage without regard to any time interval, working slower when required and making up for it when possible; an extra man in the boat as recorder and for signaling was eliminated and the instrumentmen did not have to read watches and record sounding time. There was no difficulty in taking soundings at the rate of two to the minute, at times; yet at other times, there were delays of several minutes.

Transit Stations—Two transits were used in the regular way at established stations. They were properly oriented and with the upper motion clamped only sufficiently to hold any set position, the instrumentman followed the suspended sounding chain until the leadsman by blowing his whistle gave notice of a sounding, when the alidades were stopped and the horizontal angles read and recorded.

*Assistant Engineer, Public Service Commission, 1138 Whitehall Bldg., New York City.

Each [illegible] had the regulation transit fieldbook, with lines numbered consecutively to check with the leadsman's signal at each fifth sounding. One of the [illegible] was ruled to show, in addition, the tide-gage reading, which was recorded for a change of a tenth. In addition to these columns, for horizontal angles and gage readings, columns were prepared for recording the soundings transferred from the leadsman's cards, and another for those soundings when reduced to mean low-water datum.

Illinois Road Cross-Sections

Standard cross-sections of Illinois state-aid roads are divided into two general types: those for the single-track roads, and those for double-track roads, with intermediate forms as noted below.

Where it is decided that the traffic will be accommodated by a single-track road, the paved portion is 10 ft. wide, if constructed of concrete or brick. This width is sufficient for a single line of vehicles and will also permit two vehicles to pass with only two wheels of one of the vehicles off the paved portion of the road, the other having all four wheels on the paved road. A modification of this section, offering a somewhat greater convenience than the single-track road alone, are the sections which provide in addition to the 10-ft. paved portion of concrete or brick, 4-ft. macadam shoulders on either side. It is anticipated, however, that this section in first construction will be used only on those roads where it may seem that double-track roads should be provided but, owing to the limited funds that may be at hand, together with a doubt that might exist as to the necessity for the double-track road, it is decided not to build an 18-ft. double-track road. Usually the macadam shoulders will not be provided in first construction, as they may be placed fully as cheaply after the road is built and when the traffic needs demonstrate the necessity for them.

As all the principal roads now carry a considerable proportion of motor traffic, and moreover as this proportion of motor traffic is fast increasing, it is necessary to take this fact into consideration in the proper design of the road. Experience has proved that to provide safely for two lines of mixed traffic, 18 ft. is the minimum width. It is apparent, therefore, that any width between 10 ft. and 18 ft. is uneconomical, because the traffic either requires the double-track road and therefore the road is too narrow for the traffic, or the traffic does not require a double-track road, in which case it is wider than is necessary.

The single-track roads for macadam construction, which will be used to some extent on the lower traveled roads in the south portion of the state, provide 12 ft. for a single-track road. The reason for a 12-ft. macadam rather than a 10-ft. is that the traffic on the 12-ft. road will tend to spread itself somewhat more evenly over the surface of the road and [illegible] and [illegible] the wear [illegible] as would be the case if a narrower road were built. With the paved brick or concrete surface, which will resist the wear, it is not so important that the traffic spread over the road as in the case of a macadam surface. [A. N. Johnson, formerly Chief Engineer, Illinois Highway Commission, in the [illegible] Bulletin of the Highway Department.]

Permanent Survey Monument for Southern Louisiana Reclamation Projects

A concrete survey monument, which has been used with success for marking important property corners in marshland in southern Louisiana, is illustrated in the accompanying sketch. It is built of cement mortar in a form made of common 5-in. iron stove-pipe. The sand and cement are mixed dry, two parts sand and one part portland cement, packed in cement sacks, each sack holding 0.75 cu.ft., and carried into the field. Two sacks are required to make one monument.

Concrete Monument Designed by Arthur M. Shaw, New Orleans, La.

Two lengths of stove-pipe are placed in the hole. The mortar is mixed moderately thick; in marshy ground a rammer is used to crowd out a small amount of mortar at the bottom to form a spread base. After the hole is backfilled with carefully tamped earth, the remaining mortar is deposited around the top of the monument as shown. A [illegible]-in. bronze bolt is pushed into the soft mortar flush with the top of the monument. The pipe is left in the ground.

The advantages of this type of survey marker are permanence, easy construction by ordinary laborers, easy transportation of materials, readiness with which the materials may be secured and their cheapness; the pipe forms are the cheapest grade of black iron stove-pipe, which comes "nested" in convenient shape.

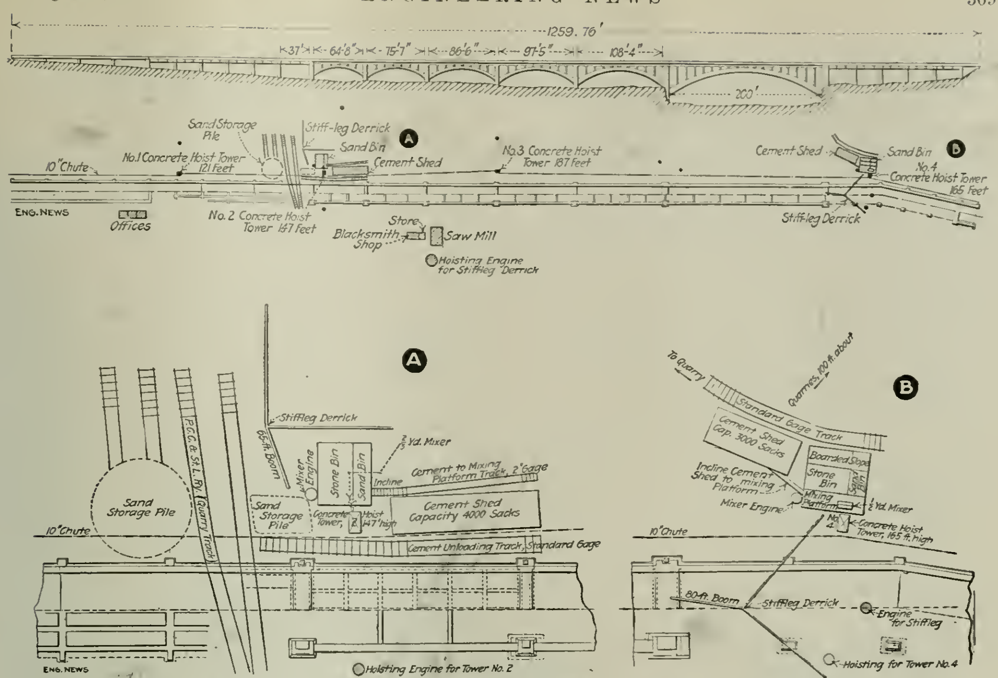
Iron pipes have been extensively used for markers of similar kind, but even galvanized iron rusts very rapidly, the destruction being most pronounced at the ground surface. Black iron pipe could not be depended upon in such locations to last more than two or three years. The monument shown was devised by Arthur M. Shaw, [illegible] Hennen Bldg., New Orleans, La.

Construction-Plant Layout for a 1200-Ft. Concrete Arch Bridge

By J. P. Kaufman*

A concrete bridge, known as the Williams Bridge, is now under construction over the Scioto River in Franklin County, Ohio. The bridge is located at Marble Cliff, several miles northwest of Columbus, and is to replace an old wooden structure carried out by the flood of March 1913. The new bridge has a total length of 1,[illegible] ft. 3 in. and is [illegible] ft. wide over all, with a [illegible]-ft. roadway and two

*Resident Engineer, [illegible], Columbus, Ohio.



Layout of Construction Plant, William's Bridge, Columbus, Ohio

2-ft. sidewalks. It has six arches of the ribbed type with varying spans, the main arch over the river having a clear span of 195 ft. At either end of the arch spans are several girder spans, and retaining-wall abutments. The concrete, exclusive of the railings, totals 4750 cu.yd.

At the present time most of the construction equipment has been installed. The east retaining-wall, east girder spans, and some of the arch piers, have been poured, and work is progressing westward. The drawing herewith shows the layout of the plant.

The main concrete-mixing plant is on the east side of the river near Pier 6. Here a stiff-leg derrick with 65-ft. boom is installed, commanding the quarry tracks, on which the materials are delivered. It operates a clamshell bucket with which the sand and stone are unloaded from cars and delivered to hopper-bottom storage bins, discharging by gravity to a measuring bin above a ¾-yd. Cube mixer. Incoming cement is unloaded from cars onto small push cars which deliver the cement to a shed, having a capacity of 4000 sacks. Cement from the shed is loaded into a car, pulled up an inclined track by means of a hoist on the mixer, and dumped onto the platform.

Concrete is elevated in Tower 2 (147 ft. high), and is delivered through chutes to a bucket in Tower 1 (121 ft. high), or to one in Tower 3 (187 ft. high), or direct to the bridge. At Towers 1 and 3, the concrete is again elevated and delivered through chutes to the various parts of the bridge.

This east-side mixing plant is to supply all the concrete required for that part of the bridge east of a point 20 ft. west of Pier 11.

There is an auxiliary concrete-mixing plant now being installed on the west side of the river. Here crushed limestone will be delivered in small side-dump cars directly from the quarries, which are in the immediate vicinity. The stone and sand will be dumped into bins discharging by gravity to a measuring hopper above a ½-yd. Ransome mixer. The cement will be unloaded into a shed having a capacity of 3000 sacks and, as needed, will be delivered by gravity to the mixing platform. The concrete is elevated in Tower 4 (165 ft. high) and chuted.

The chutes, hoppers, etc., are standard Insley equipment. Steel cables ⅞ in. in diameter are stretched over the tops of the towers to deadmen. From the cables, 10-in. chutes, inclined 30° with the horizontal, are hung on ¾-in. manila rope suspenders. Tower 3, which is a typical one, is 3½x6 ft. in plan and has four 6x6-in. posts braced with 2x10-in. transverse and 2x6-in. diagonal planks, all connections being bolted. Each tower has four sets of four guys.

Water is pumped from the river to a tank located on a large pile of quarry waste and is distributed by gravity.

The 225 tons of reinforcing steel are bent by hand on the job.

The arch piers are being constructed in open sheeted excavations which are carried to bedrock. The maximum depth of excavation is about 35 ft. The excavating for all the arch piers except 11 and 12 is being done by means of a stiff-leg derrick, with 40-ft. boom and ¾-yd. buckets. Derricks with 80-ft. booms are installed near Piers 11 and 12 and will be used to remove the sandstone abutments and pier of the old bridge, to excavate, and to drive the piling for the centering of the main arch.

The contractor for the bridge is D. W. McGrath; E. C. Miller is contractor's superintendent. John Peake is County Surveyor, Walter Braun is County Bridge Engineer, W. J. Watson & Co. are the consulting engineers, and the writer is Resident Engineer.

Load-Tests on Concrete Piles, North Side Point Bridge Approach, Pittsburgh

An acceptance load test of the concrete piles used for the foundation of the piers of the approaches to the North Side Point Bridge, Pittsburgh, Penn., was made on one pile in each of the eight pier bases. The tests were made under the specifications of the Director of Public Works of the city of Pittsburgh by the Raymond Concrete Pile Co., whose familiar cast-in-place concrete piles were used on the work.

The approach piers are founded in a sedimentary deposit of sand and loam, overlying a gravel bottom, into which it is quite difficult to drive or sink piles. Consequently the piles were short, the piles varying in length from 13 to 23 ft. and averaging about 17 ft. They were uniformly 8 in. in diameter at the point and increased in diameter toward the top at a rate of 0.4 in. per foot of length. The specifications under which these tests were made are as follows:

TIME OF TESTING.—[illegible]

[illegible]

base will be selected by the director for testing. In case any or all the piles tested fail to fulfill the requirements hereinafter specified the contractor shall, if ordered by the director, make tests of other piles in the groups in which the tests have failed without additional compensation. All piles for testing shall be selected by the director.

ADDITIONAL PILES.—In cases where the tests of a group shall fail to meet the hereinafter specified requirements, the entire group in which said test piles are located shall be considered the same as the test pile and their safe carrying capacity shall be considered one-half the load of said test pile when it gave a settlement of ¾ in. and the contractor shall drive such additional piles and at such locations and depths as ordered by the director.

Additional piles made necessary due to failure of test piles to sustain the specified test shall be driven where directed by the director and to penetration of surrounding piles at the expense of the contractor.

PREPARATION OF PILES FOR TEST.—The piles selected to be tested shall have placed in their top a suitable steel dowel or plug, securely grouted in place, with its top round, and the test loads shall be so placed that a level rod can be set on the plug at any or all times.

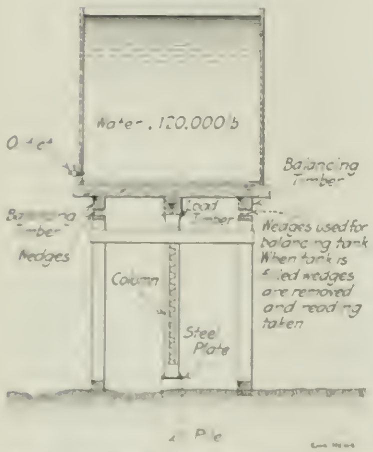


FIG. 1. METHOD OF SUPPORTING 60-TON LOAD ON TEST PILE

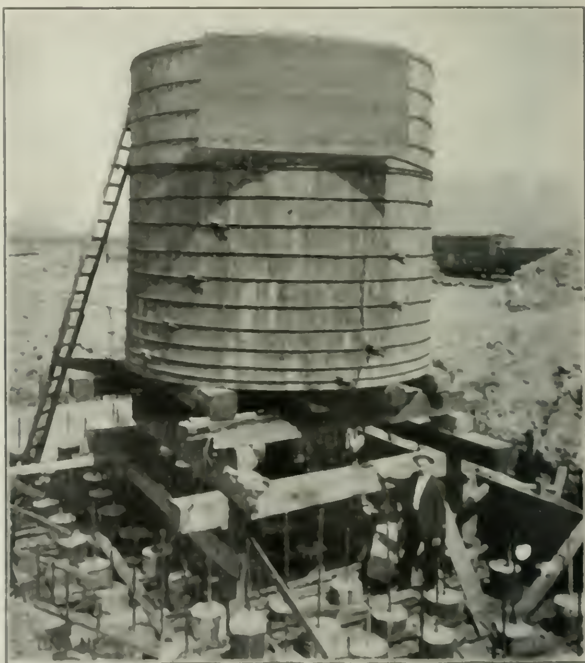

FIG. 2. ONE OF THE PILES UNDER TEST

Upon the pile shall be placed a suitable platform properly balanced so that the test load acts vertically on the pile.

LOADING.—Upon this platform there shall be placed a load of 60 tons, which shall remain undisturbed for 48 hours; the load shall then be increased to 90 tons and allowed to remain undisturbed for 48 hours. The load shall then be removed.

READINGS.—The following readings shall be taken: First, before any load or platform is placed upon the piles; second, immediately after the 60-ton load has been placed upon the pile; third, 48 hours after the 60-ton load was placed upon the pile; fourth, when the 90-ton load has been placed upon the pile; fifth, after the 90-ton load has been placed on the pile

[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]

sixth, immediately after the 60-ton load has been placed on the pile; seventh, 36 hours after the 60-ton load was placed on the pile; eighth, when the load on the pile has been reduced to 30 tons; and ninth, immediately after the entire load and platform have been removed from the pile.

ALLOWED SETTLEMENT—The pile, to be acceptable, must not show a settlement exceeding ¼ in. between the first and third readings, or a settlement exceeding ⅜ in. between the first and seventh readings, or a variation between the first and ninth readings exceeding $\frac{5}{16}$ in.

BEARING POWER—The bearing power of each group of piles will be determined by the director from all available data for each particular group and will be based on one-half the load which causes a settlement of ⅜ in.

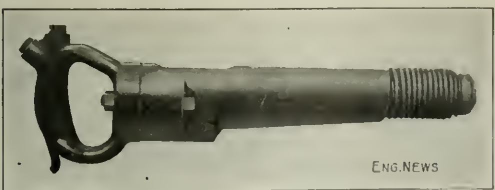
The accompanying diagram, Fig. 1, shows the testing rig. First, a circular steel plate was grouted on to the head of the pile under test and on this was placed a latticed steel column, 13 ft. long, which carried balanced on its top the loading timber on which rested the tank framework. As shown in the view, Fig. 2, side posts were also placed which carried the tank framework, through the medium of wedges, until a balance was attained. When the wedges were struck the tank, carrying the desired load of water, rested on the pile under test. Settlements were read upon a level rod set upon a reinforcing bar which protruded up from the pile through a hole in the plate cap provided for that purpose.

The results of the tests are given in the accompanying table.

The tests were under the direction of N. S. Sprague, Superintendent, Bureau of Engineering, City of Pittsburgh, and under supervision of W. F. Hall, District Manager of the Raymond Concrete Pile Co., for the Pittsburgh District.

NOTES

A Simple Riveting-Set Retainer for preventing accidents consequent to the ejection of the rivet set from the nozzle has been developed by the Ingersoll-Rand Co., 11 Broadway, New York City, for its line of "Little David" pneumatic riveting hammers. The retainer is a steel spiral spring, one end of which fits over a projection on the hammer nozzle; the other end is wound to a smaller diameter, so that the rivet set when for ⅞-in. rivets or smaller can be formed with a shoulder and slipped into the retainer. The larger sizes of riveting sets are formed with a coarse thread and screwed into place. It is claimed that the riveting sets cannot be driven out of the nozzle even when the hammer is run free under 90-lb. pressure per sq.in.



In the Graphical Determination of the Neutral Axis in a reinforced-concrete beam, discussed by Ernest McCullough, in "Engineering News," July 9, 1914, p. 88, a correspondent notes that the method fixes $\frac{k}{1-k} = \frac{n+1}{m+1}$ instead of $\frac{k}{1-k} = \frac{n}{m}$, which is the correct ratio according to the accepted theory. Mr. McCullough explains this discrepancy as follows:

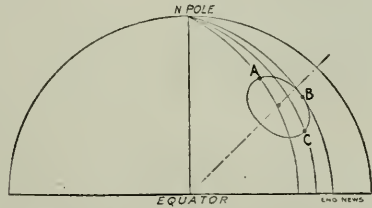
I have been teaching evening students for several years, draftsmen in the offices of architects, engineers and contractors whose mathematical attainments are very limited. With the great amount of free literature floating about it is useless to tell such men not to design, because they will attempt it anyhow. The thing to do is to give them instruction. I found it difficult by using the ordinary mathematical expressions to get into their heads the idea of how two differing ratios, the ratio of deformation and the ratio between stresses, fixed the location of the neutral axis. One evening I drew the two lines on the squared blackboard and the results were so nearly exact that I investigated the matter and found, naturally, that the relations were true. But in handling the students it was still difficult to make many understand where the ratio 1 : 15 and 1 : 24.66 came in without extending the ratio to the left of the line one division. With it in that shape their understanding of the matter seemed complete. The results were as close as ordinary accuracy in design requires, so I have held to this graphical representation in teaching and after the students grasped it showed them the relations actually existing and showed also that by omitting the division to the left of the line the mathematical expression and the graphical representation agreed.

A Problem in Astronomy—A correspondent in Philadelphia, Penn., proposes the following problem, which he has met with in his work, for any of our readers who wish to exercise their ingenuity in spherical trigonometry and astronomy, or solid analytical geometry:

Having given three points, all located in any one quadrant, upon the surface of a sphere, to find the center of the circle passing through the three points.

In the figure, Point A is Lat. 40°-00′ N.
Long. 82°-00′ W.
Point B is Lat. 38°-00′ N.
Long. 82°-00′ W.
Point C is Lat. 39°-00′ N.
Long. 80°-00′ W.

Required to find by a short formula, the latitude and longitude of the point x, the center of the circle, drawn on the surface of the globe, and passing through the points A, B and C.



A Hand Concrete Mixer was used in the construction of the new combined concrete and timber snowsheds of the Great Northern Ry., described in our issue of June 4. While ½-yd. power mixers were used for the heavy work of the retaining walls or back walls, the hand mixer was used extensively in making the concrete for the pedestals which support the timber posts for the roof. This arrangement worked out very conveniently, as the pedestals usually could not be built when the backwall was being built, while the amount of concrete in each was so small and the work so scattered that the concreting could be done in this way more economically than with a power mixer. The machine was built by the T. L. Smith Co., of Milwaukee, Wis., and had a 36-in. drum of about 2½ cu.ft. capacity, 32 in. long, on each end of which was an internal gear meshing with a pinion driven by a crank handle. The charging and dumping were done through openings extending across the drum, and the concrete was dumped directly into the forms, the machine being carried by a pair of 30-in. wheels so that it was easily shifted from place to place.

Designing Shallow Girders for Limited Deflection—R. C. Davis, Chicago, suggests a simple and convenient method for designing shallow girders under the rather common condition that the deflection of such a girder must not exceed the deflection of a girder of particular ratio of depth to span. Many railway specifications for steel bridges contain a clause such as the following:

Plate-girders and rolled beams used as girders shall preferably have a depth of one-twelfth of the span. If shallower girders or beams are used, the section shall be increased so that the maximum deflection will not be greater than if the above limiting ratio had not been exceeded.

In designing a shallow girder under this clause, it is customary to design first a girder having a depth of one-twelfth of the span, determine its moment of inertia, and then design the shallow girder for the same moment of inertia, which will make its deflection the same. Instead of making this double calculation, proceed as follows:

Having given the maximum allowable fiber stress, say 16,000 lb. per sq.in., design the shallow beam or girder in the usual manner, but with a fiber stress reduced in the same proportion as the depth of beam is less than the deeper girder whose deflection is taken as standard. For instance, in a span of 24 ft., if the normal limit is a depth of one-twelfth the span, or 24 in., but local conditions require a girder of 20-in. depth, then design the 20-in. beam for a fiber stress of $\frac{20}{24} \times 16{,}000$ or 13,300 lb. per sq.in. The 20-in. beam

[illegible] in this way will have the same deflection as the [illegible] beam designed for [illegible] lb. per sq.ft. Thus the value of $\frac{I}{c}$ will be $\frac{33}{24}$ of that which would be used for a 24-in. [illegible] and since the [illegible] is [illegible] $\frac{33}{24}$ the value of [illegible] for the [illegible] the values of I of the two beams will be [illegible], and thus [illegible] equal deflections.

An Improvised Gravel and Broken-Stone Spreader—A simple [illegible] designed by a motor truck mechanic [illegible] shop, eliminated the labor of [illegible] on the construction of a gravel road in [illegible], Tex. The device is nothing but two simple [illegible] which hold the tailboard of the truck partly open at the bottom, which it [illegible] hinged at the top. The catch has three adjustments for regulating the quantity of stone

Peerless Motor Truck Equipped with Gravel Dumping and Spreading Device

or gravel dumped. It was found by a few experiments that if the power dumping [illegible] was tripped in the usual way, and the truck thrown into the first speed ahead, the material was dumped and at the same time spread evenly to a depth of 6, 8 or 12 in., as the circumstances required. Two Peerless motor trucks were used to haul the gravel, which at first was dumped in piles in the middle of the road. The [illegible] of this simple device saves the labor of three or four [illegible].

Success of a Municipal Ditching Machine—The city of Worcester, Mass., does practically all its public work by municipal day labor and does the work efficiently. The accompanying views shows a municipally owned Austin trenching machine at work. The machine was purchased by and is part of the equipment of the city Water Department, of which George W. Batchelder, Water Commissioner, is in charge. The work on which the machine is employed is a 3-ft. sewer trench 12 ft. deep in a very hard hardpan containing numerous small boulders. The ditch was excavated by the Water Department for the Sewer Department at the rate of 39.2c. per cu.yd., based on a charge of $25 per day. The actual cost of operating the ditcher is stated by Mr. Batchelder to be very close to $15 per day. On a water-pipe laying job a trench was dug 6 ft. wide and 6 ft. deep, through various kinds of material, mostly gravel, in an actual operating time of 123 hours [illegible]35 ft., or nearly a mile of trench, was excavated. The trenching machine was recently inspected on the work illustrated by members of the New England Water Works Association, who expressed much satisfaction with its ease of operation and efficiency. Perhaps there is not better proof of Worcester's honest and progressive municipal day-labor administration than the fact that no protests have been received against the introduction of a machine which disposes with the services of several extra laborers.

Ground-Glass Drawing Boards—A sketching board for use in the drafting room in laying out sketches, details and illustrating portions of drawings for detailers, salesmen and customers, is one of the handiest things that a well equipped drafting room can have. Similar in use to the old-fashioned slate, the ground-glass drawing board painted black on one side, serves this purpose admirably.

A fine, evenly ground surface should be used to work on and the reverse side of the glass should be given two or three coats of smooth, black paint. The edges of the glass board should be squared to allow the use of a T-square and triangles. Small slate pencils are best for sketching and should be kept sharp by means of the ordinary sandpaper pad. Erasing is easily accomplished by means of a damp sponge or soft cloth, thus eliminating the dust and dirt incident to art gum or other erasers.

Such a board is especially useful when laying out preliminary sketches which mean constant changing and redrawing. The great saving in drawing and sketching paper is quite obvious. Glass boards up to 2 or 3 ft. square need not be mounted and can be used on any table with the ordinary precautions against breakage. Boards larger than this size should be mounted in a frame and adequately supported in a permanent location. [Frank H. Jones, 95 Partridge Ave., Winter Hill, Mass.]

Stiffleg Derricks are not now in favor with contractors on bridge and steel erection work, according to an erecting engineer. They may be used as yard derricks to unload the steel, but they are too cumbersome for erection, especially on bridge work. They may be used, however, when built as portable machines or "mule" travelers, mounted on trucks or flat cars, particularly for the erection of long steel-frame sheds or buildings at industrial plants. The use of stiffleg derricks at the plant of the Lima Locomotive Co. was described in our issue of May 7. For high steel office and warehouse buildings the preference is for guyed derricks.

Austin Trenching Machine Owned and Operated by the City of Worcester, Mass.

Editorials

On account of the European War and its consequent effect on American markets, the regular "market prices" supplement to ENGINEERING NEWS, which usually appears in the first issue of each month, has been postponed.

Federal Aid to Road Construction Unlikely

According to a recent Washington dispatch, the Senate Committee on Post Offices and Post Roads, of which Senator Bankhead of Alabama is Chairman, has agreed to report favorably the Federal aid scheme of Ex-Senator Jonathan Bourne, Jr., of Oregon.

Mr. Bourne's scheme was explained and criticised in our issue of May 22, 1913. In general his proposition was to lend the credit of the Federal government to such of the States as desire to borrow money for road construction, the total amount of Federal aid being limited to half a billion dollars. The National government would issue 3% bonds for this amount and would take 4% State bonds for the money it advanced, the difference of 1% forming a sinking fund for the payment of the bonds at maturity.

The chief objection to the Bourne scheme is the objection which attaches to all schemes for building roads with borrowed money; to wit, that the roads to be built will be worn out and gone long before the bonds issued to build them fall due. If the life of bonds issued to pay for road construction or paving were limited to the life of the roads built from the proceeds of the bonds, the objections would be much less serious. But almost invariably states and counties and cities which are building roads and paving streets with borrowed money raise the money by bond issues running twenty-five to fifty years. Part of the colossal debt under which New York City staggers is made up of bonds issued to pave streets on which the pavement already has been renewed two or three times since the bonds were first issued. The present generation of taxpayers is already loaded down with burdens from which they receive no corresponding benefit; they ought not, therefore, to lay increased burdens on the generation which is to follow. For the Federal government to encourage the several States to continue such financial folly would be a crime.

It may be shrewdly suspected that the reason why the Senate Committee has reported this bill of Senator Bourne's is because of its disinclination to report favorably the almost equally foolish House bill for Federal aid to roads, passed some three months ago.

There is considerable reason to believe that both the Senate bill and the House bill were intended rather for political effect than as measures intended for enactment into law, and that neither House or Senate seriously intends to enact any Federal aid to Highways law at this session.

The Water Supply of the Panama Canal

It requires no long memory to recall the dire predictions made only a very few years ago of disaster to the Panama Canal enterprise because, among other things, there was not water supply enough to provide for the traffic. These prophecies of evil were not confined to irresponsible writers for the newspapers. Some learned engineers wrestled with columns of figures and attempted to show that by allowing enough evaporation from the surface of Gatun Lake during the dry season, the level of that body of water would be reduced so low before the end of the season that the traffic would be interfered with.

It is of interest for this reason to compare with these prophecies the results of actual experience. Traffic is not yet passing through the canal, it is true, but during the recent dry season the surfaces of Gatun and Miraflores Lakes have been held at substantially the level they will be when the canal is open. Accurate records of the outflow from Gatun Lake, therefore, enable a close estimate to be made as to what amount of water will actually be available for purposes of lockage.

The *Canal Record* of July 8 summarizes the results of measurements of evaporation and outflow, and the conclusion may be summarized in a single sentence, which we quote as follows:

> The record of the season of 1912, in which the runoff from Gatun Lake watershed was the smallest observed during the past twenty-two years, demonstrates its capacity for all the traffic that can be brought through the canal.

Stating the figures in more detail, the assumption is made that Gatun Lake was at an elevation of 87 ft. above sea level at the beginning of the dry season on Dec. 1, that the hydro-electric plant at the Gatun spillway was continuously operated, and that 48 lockages a day were made. Under these conditions the surface of the lake would be reduced 7½ ft. to 79.5, on May 7, at the close of the dry season. At this elevation the depth of water through Culebra Cut is 39 ft., which is ample for navigation. This average of 48 lockages a day may be compared with the average number of lockages through the Soo Canal on the American side, which was 41.7 per day during the navigation season of 1912. During the eight months of navigation, the Soo Canal in that year passed 14,916 vessels, while the Suez Canal in the same year passed only 5373 vessels. According to these figures, therefore, there is water enough at Panama to handle probably three times as much traffic as now passes via Suez.

The Pittsburgh Sewer Explosion Repeated

A mile length of large trunk sewer blew up in Pittsburgh eight months ago, and since that time a couple of hundred thousand dollars have been spent in rebuilding the wrecked sewer. With this rebuilding work nearly

completed, on July 28 another explosion occurred in the same sewer. Fortunately this time the sewer was not wrecked, yet the explosion deserves to be classed among the violent sewer explosions on record.

Both last November's explosion and the explosion of July 28 appear to have been due to the same cause, namely, gasoline in the sewer. Because the first explosion destroyed such a large part of the sewer there was little chance to determine the cause with any great certainty. Whether for this reason, or not, the city authorities appear to have been a little reluctant about proceeding at once to take stringent measures against the discharge of inflammable wastes into their sewers. Now, after the second explosion, prompt action will undoubtedly be taken and the public will support the authorities in any necessary measures.

The following brief statement of facts of the second explosion is of interest:

The explosion occurred at 9:10 a.m. July 28. Gasoline odor was detected the day before. A quarter-hour before the explosion ten or twelve men working inside of the sewer on repairs were ordered out as the gasoline fumes became so strong that they could not remain inside. As electric lights were used in the sewer work, it is not clear how the gas became ignited.

The explosion was not serious. Damage was confined principally to breaking of glass in the adjoining mill of the Carnegie Steel Co. The explosion apparently did not extend beyond the length of sewer between the Allegheny Valley R.R. tracks and the sewer outlet. The explosion traveled through the pipe gallery of the steel company opening into the sewer and blew up plates in the mill, also damaging the roof, etc. A few men in the mill were injured by falling glass. The explosion made a loud report, not a muffled one, as in the former case. Working shafts and manholes were open, which probably reduced its force. Flames shot high in the air.

The U. S. Bureau of Mines is working in conjunction with the city authorities in investigating the case, locating sources of inflammable waste, etc.

In furnishing a striking example of the great danger residing in sewer explosions or in the existence of causes which may produce sewer explosions, this second Pittsburgh case is a valuable one. The recurrence of the explosion in the same sewer reinforces the proof by showing that the explosion of last November was not an isolated case, but an occurrence due to a continuously existing cause. It is now the city's duty to find and remove that cause.

A Catastrophe without a Parallel

With almost the suddenness of lightning from a clear sky there has come upon the world during the past week the sudden outbreak of a war involving all the great powers of Europe. Of the vast disaster involved in such a war, it is well nigh impossible to conceive. The whole civilized world is aroused to sympathy and offers of aid when by some cataclysm of nature or some failure of man's work a few hundred or a thousand people lose their lives and a few million dollars' worth of property is destroyed. But the destruction resulting from such a conflict to the death as that which has begun in Europe may cause, in a very short time, the death of a million men and the destruction of wealth amounting to a billion of dollars.

It is difficult for even the most farsighted of economists or statesmen to forecast the results which may follow from this war; but it has already been made evident that even the threatening danger of such a war has had far-reaching results in our own country. The universal upsetting of values which swept over every country of Europe within the space of two or three days was felt immediately in our own country, and compelled the closing of every American stock exchange and of many of the exchanges in which other commodities are bought and sold.

Some of the amateur statesmen in our legislatures and even in Congress have been for years agitating against these exchanges, and have sought to close them by process of law. Now that this result is actually brought about by other causes, thousands of business men in all parts of the country find themselves in serious difficulties because of the loss of the facilities which these exchanges afforded.

It has been often and truly said that the United States is probably nearer to absolute economic independence than any other country in the world. When the emergency required, she could close every port, mount a guard on every frontier and absolutely cut off all intercourse with foreign nations. There would be little difficulty, when once the economic adjustment was effected, in supplying all our own requirements, both as to food products and manufactured goods. But nothing short of stern military necessity could compel such an economic readjustment; and the loss and suffering and disaster involved in making it would by itself constitute an overwhelming calamity.

In the year ending June 30 last, government statistics, made public on Aug. 5 by the Department of Commerce, showed that we imported from foreign nations goods to the value of $1,893,000,000, and we sent abroad during that time $2,364,000,000 worth of goods. Over a billion dollars' worth of this was in the form of finished manufactures.

The United States is just harvesting probably the greatest grain crop it has ever secured. The European war will make an enormous market for foodstuffs. It seemed at first that the clash of armies on the plains of Europe meant the opening of a gold mine for a million American farmers, but the eager speculators for a rise on the exchange were suddenly confronted with the problem of how the grain was to be transported and delivered to the warring nations in Europe. With all the great naval powers of Europe engaged in a life and death struggle, any merchant vessel taking wheat to the port of a hostile power would be subject to capture. Doubtless the wheat will go, in some way, for food is as necessary to the armies (which, as the saying is, travel on their stomachs) as are guns and ammunition; but the heavy risks involved in its transfer across the ocean and to its final destination may absorb so large a part of the final price that the American wheat grower or wheat dealer may have his expected large profits turned into a loss. This is merely a typical illustration of the dangers and perils and sudden changes which this unprecedented war may bring about. Many thousands will doubtless be made suddenly rich by these lightning changes in the markets and in industry, but many other thousands will as suddenly find themselves facing poverty.

The events of the past week have furnished a marvelous illustration of the extent to which modern commerce and industry is governed by international conditions in economics and in finance.

In the preparation for war during the past week, all the nations of Europe have been grabbing for gold, and not only the nations but the financiers, and not only the financiers but the people. Every French peasant, merchant and manufacturer besieged the banks, seeking to draw his savings in the form of gold, to be carefully hoarded for use in dire necessity. Similar occurrences went on in Germany and even in England. Indeed it is doubtful whether the United States itself could long retain its stock of gold if the doors of international exchange were left open so that Europe could find means to obtain the precious metal. On the other hand, however, there may come a backward flow of gold to this country as soon as the nations abroad, under the stern pinch of necessity, are obliged to have our food products and our manufactures and have nothing to buy them with but gold, because of the stoppage of their own production.

One of the most certain results of a great European war will be a world-wide scarcity of investment capital and a consequent rise in the ruling rate of interest. Indeed such a rise has already taken place, partly as a result of the wars fought during the last dozen years and even more of the preparations for war on an enormous scale which the European nations have made. About the close of the 19th Century, prior to the Boer War in South Africa and the Spanish-American war, the market value of investment funds in the highest-class securities was not far from 3%. During the past year or more the average price has been probably 4 to 4½%. Where the price of capital will go to in the event of a general European war, long continued, can only be conjectured. Such a war would destroy to a large extent the great reservoirs of investment capital in the principal European nations, to which all the rest of the world has resorted for the funds with which to carry on economic and industrial development. It may easily be that a year hence 5% or 6% or even 7% may be the ruling price for investment funds of the highest class. The rate on funds invested in ordinary enterprises, involving more or less risk, such as attaches to almost every private enterprise, must, of course, be correspondingly higher.

The far-reaching results of such a change in the value of capital it is impossible to foresee in full detail. It would have, of course, a vast effect upon the prices of commodities of every sort and of real estate. It will greatly limit the carrying out of works of permanent improvement, in which engineers are so largely concerned, since capital will be difficult to obtain and can only be secured at a high price. It will mean the cancellation of a great number of new enterprises because the reservoirs of capital that were to have sustained them will be dried up.

It can only be hoped that the emergency may bring about new demands for industry and ability to offset those that are cut off. This may indeed be the case. Practically the whole world is dependent on Europe and the United States for its supply of manufactured goods. But from now on the factories of Germany and France and England will be barely equal to the demands made upon them for home consumption, depleted of their labor forces as they will be by the call to arms. In South America, in Africa, in Asia and even in Australia, therefore, manufacturers of the United States will find markets for their products never before opened. A way must be found, of course, to transport these goods across the seas. Doubtless the matter of naval supremacy will be the first to be settled, and if this should result favorably to Great Britain, the British merchant marine will be as available for this work as in the past. We shall doubtless see also a powerful movement to create an American merchant marine, and Congress may revise our navigation laws so that this result may be achieved.

Of especial interest to many engineers is the question what is to be done concerning the half dozen great international engineering congresses which were scheduled for next year.

Besides the great international engineering congress to be held in San Francisco, together with numerous other international congresses relating to many branches of science and industry arranged for there, the International Railway Congress was to assemble next year at Berlin, the International Society for Testing Materials at St. Petersburg, the International Navigation Congress at Stockholm and the Congress of Mining and Metallurgy at London. Doubtless all these congresses will have to be indefinitely postponed. It has been suggested that the American engineers might offer to welcome these various congresses in the United States. But even if it were attempted to hold the meetings here, the attempt could hardly result otherwise than in failure. With the great nations of the world at each other's throats, it is not to be expected that their representatives, many of them government officials, could be brought together in peaceful and friendly conference only a few months hence. Indeed, who is wise enough to foresee the profound changes in nations, in politics, in policies, in races, which may grow out of this terrific conflict? It sounds like a mockery, the circular before us regarding an international exhibition of art and civilization to be held at Dusseldorf next year. But that is only one of several such international events, including our own great exposition at San Francisco, which must be either abandoned or, if held, must do without exhibits from the chief industrial nations of Europe.

It is not our function to discuss the historic causes which have precipitated this catastrophe upon the world nor to portray—what no words can portray—the incalculable suffering and misery which it brings to countless millions.

We may properly, however, point out here that in the opinion of many observers the cause of the war is to be traced not merely to deep social and national prejudice and hatred, but to the vast preparations for war which Europe has made. There is an economic limit to the burdens which a nation can bear. The competitive struggle for superiority in armament had reached the breaking point. The Europe of today has spent more by far on warfare in time of peace than the Europe of Napoleon spent to wage war. The time had come when these vast armies and navies must either be set in motion or reduced, and no nation could reduce its powers of defence without inviting conquest by its rival.

The best that may be hoped from the present terrible conflict is that when it is ended by peace, it may be a peace accompanied by universal disarmament, a peace that shall relieve the nations from those crushing burdens of preparation for war and leave them free to solve those problems of social readjustment which are the pressing problems of this century.

Letters to the Editor

Deterioration of Railway Property

Sir: I am endeavoring to obtain authoritative information relative to the physical deterioration of certain materials used in railway construction, and wish to know if data have ever been compiled that will show the ratio of deterioration of ballast, rails, ties, bridges, etc., due entirely to weather conditions, as against deterioration due entirely to wear from traffic.

For instance, it has been arbitrarily assumed that ties deteriorate 75% on account of weather conditions and 25% on account of traffic, and that ballast is deteriorated 90% by weather and 10% by traffic.

If you can refer me to any authorities or to publications treating with the above as I have outlined it, it will be much appreciated.

R. W. Le Baron,

Engineer Examiner of Joint Facilities, Chicago Great Western Ry.

Chicago, July 3, 1914.

[Probably these matters have been investigated by the railway and government valuation engineers, and we shall be glad to receive information for the benefit of our readers.—Editor.]

Highway Location in Mountainous Country

Sir—The recent good-roads crusade has marked an epoch in road building, and has been responsible for a heavier and more costly type of road construction than is really necessary or justifiable.

When state governments commenced spending millions on roads, the old "[illegible]" and "prairie schooner" passed into the limbo of a bygone day. The railroad locating engineer was called in to survey the trail for automobile and motor-truck traffic.

There is no question but that a railroad engineer was of all men best adapted for this work, but in approaching the new task, the theory of the old ideas clung to him and refused to be shaken off. The most persistent idea was the one that dealt with the grade line—the old locator would look at his Plate "A" profile paper and draw on his grades from 2000 to 5000 ft. long; the idea of breaking grade every 200 to 300 ft. if necessary, he felt to be a sacrilegious act on the part of one who had sat at the feet of Wellington.

The early freighting of the west was done over roads that had some of 20% and 25% grades. One would not say these were desirable, but they were the best the country afforded at a reasonable cost.

State roads are being built over mountain ranges in the West where the distance development is excessive, and where the maintenance cost will always be a constant tax on the road, solely to appease the worshippers of the 5% maximum grade fetish. To do this, they are willing to loop the loop, build figure 8's and design a road looking like a Moorish maze—in other words they go all around Riley's barn to get to the door.

At least 90% of the future traffic on these roads will be by power-driven vehicles, where distance is a greater factor than grade. It would be better in mountainous country to build 2 or 3 miles of 8% grade to cut out one mile of distance.

Action and re-action; it is the same old story; from having roads with 20% we have gone to the other extreme of 5%. No engineer in the State of Washington will be able to use his judgment on the matter for a state law has been passed to tie him down to 5%. In rough and rolling country one should never hesitate to break grade to keep down construction costs, taking care that the drainage is being cared for as well.

Highway location is still in its infancy, a few more railroad ideas will have to be almost forgotten. There is as much difference between a road and a railroad, as there is between an oak and cherry tree.

An 8% grade is low enough for a maximum grade in the mountains or very rough hilly country, and will result in a better road in every respect. It is, of course, presumed that the locator will only use a higher rate of grade when necessary, and only after a careful trial of a lower rate.

Regarding curvature—anything up to a 40° curve is allowable on mountain work. Curves of 20° and upward can be used in any place, where the P. C. and P. T. are in sight along the long chord of the curve.

This letter is only a plea to be allowed to use a higher rate of grade where it is shown to be necessary, especially in cutting out loops and long winding developments on mountain roads. The saving in distance, surfacing and maintaining the same, besides eliminating dangerous curves will more than repay its use.

Following the Crowd in the Valuation of Public Utilities

Sir—It is becoming less and less the privilege of modern city dwellers to see a flock of sheep in their natural habitat, but the pastoral game of "follow the leader" is ever new. Aside from inventions and their applications, there is but little really new in the principles of true engineering. However, even eminent engineers, as well as jurists, continue to enunciate "principles," "axioms," "conditions," "premises," "rules," "variations," etc., concerning the valuation of public utilities, as if there was something radically new about it, and others, striving to keep in the procession, immediately rush into the field, with notions similar to those of their fourfooted friends before mentioned.

As a matter of fact, scarcely have there been two im-

portant cases, so alike in conditions, that any one set of rules would equally apply. The writer has no desire to criticize or condemn such rules as have been put forward, or to offer substitutes therefor, but rather to call attention to the foolishness of following any sets of rules or precepts or court declarations, without first giving a very thorough study and analysis to the particular case that may be under consideration.

From the earliest eras of man, transfers of the ownership of property and rights have taken place, either solely through direct negotiation between the parties interested, or with the aid of friends called in to depreciate or bolster up the respective ideas of value; in more difficult cases, there has been resort to supposedly impartial judges. Now what more is it today? Nothing—except that in the sharper business competition of the present, perhaps greater general injustice prevails, with less regard for personal rights and consequently more frequent recourse to impartial tribunals.

As against some greater disregard for personal rights, there is a growing public view that corporate rights, as represented by real investment in public utilities, must be protected and the actual investor of money and brains, be guarded against too great a Socialistic sentiment; hence the multitude of legal proceedings to establish rates and values. These result in great masses of testimony, too rarely well digested, concerning original cost, cost of reproduction, going value, depreciation, earning value, reasonable profit, etc. Almost without exception, however, in the cases noted in very recent years, local circumstances have very properly had a strong influence in final determinations.

A privately owned public utility may be the chief means of developing a community, yet that fact may not be reflected to large extent, in the costs of construction or operation, or in its business profits at time of proposed public acquisition, while the future might hold promise of an ultimately profitable investment. No ordinary rules of acquisition would provide for such a return as the owners should justly receive to compensate them for actual, even though intangible, results of their forethought, investment and energy; in fact, most rules as laid down would virtually penalize the owners for having entrusted their capital to works so slow in returning hoped-for profits.

All such problems need to be approached with absolutely unbiased minds and without preadopted notions of the procedure to follow. Any intelligent engineer, familiar with costs of construction, expenses of operation, actual depreciation, and the conditions attending development and carrying on of similar business, can begin to attack the problem. He must then carefully study the physical and financial history of the enterprise, the local circumstances attending inception of the project, the community attitude and response and the probable future outlook, and he must pay some attention to the business intelligence exhibited by the management in handling its trust.

If financial markets have handled the utilities securities in an active manner, one criterion of value can be set up, but not by any means a binding one, without other verification. One utility, under the writer's notice, depended for much of its value on what might be done in the future through the use of powerful influences and business acumen, rather than on earning value at the time of investigation, for its immediate sales market had been virtually lost for the time being. Yet the utility represented millions actually invested, and upon which there might well be abundant later return.

What rule or principle as yet laid down would establish a fair value in such a case? None!

Valuations are for three main purposes: (1) to secure for a community the control of a privately owned utility at a price reasonable to the public and just to the owner; (2) to secure for the public, rates for service rendered, that shall be as low as possible, yet yield a fair business return upon the capital invested and brains used for management; (3) to establish a value upon which just taxes shall be levied.

To some extent, if the "signs of the times" do not change their indication of strong Socialistic tendencies, similar policies will soon obtain, concerning other private enterprises that deal with commodities which have become necessities for public use. Discussion of that division of the subject, however, is not pertinent here.

The formulation of valuation rules is educational; the more that appraisal problems are studied, analyzed and described in detail, the better for law and engineering, and the better for clients. But beware of being sheep.

The foregoing little lay sermon was inspired by some late valuation articles, reports, and decisions with which I have been edified. The complacency of their authors, has been the immediate cause of jotting down the above comments. If they find appropriate place in ENGINEERING NEWS, I hope they may not be without service.

Design of Crane Runway Girders

Sir—In the interesting account of the new shops for the Lima Locomotive Corporation, given on p. 1002 of your issue of May 7, I notice that an 80-lb. crane rail on an inverted 15-in. channel is described as "resting" on the top flange of the runway girder. I should much appreciate further particulars of the attachment of this channel to the top flange, as from theoretical considerations the more rigid it is the less economical is the combination for resisting the horizontal side thrust.

This paradox can be explained as follows: If the channel is designed to take side thrust and is not made part of the runway girder designed to take the vertical load, the extra stress in the channel, due to the vertical load, will be very small, as the total vertical load will be carried by the channel and girder, each taking an amount directly proportional to its moment of inertia.

If the channel is securely riveted to the top flange, the vertical load will cause it to be more highly stressed than any part of the top flange, so that less side thrust than before is needed to stress it to its maximum allowable limit unless the girder itself is very strong sideways.

The strength relations of the channel and girder may be expressed mathematically as follows: Let

B_h = Horizontal bending moment;

B_v = Vertical bending moment;

M_h = Horizontal section modulus of the channel;

M_v = Vertical section modulus of the girder;
f = Allowable stress in each.

If both channel and girder are designed just strong enough to deal with the horizontal and vertical loads, respectively,

$$f = \frac{B_h}{M_h} = \frac{B_v}{M_v}$$

If they are riveted together, let

$M_h(1 + a)$ = New effective section modulus resisting horizontal bending.

$M_v(1 + b)$ = New effective section modulus resisting vertical bending.

Then, if the combination is still adequate

$$f = \frac{B_h}{M_h(1 + a)} + \frac{B_v}{M_v(1 + b)}$$

That is,

$$f = \frac{B_h}{M_h} - \frac{a}{1 + a}\frac{B_h}{M_h} + \frac{1}{1 + b}\frac{B_v}{M_v}$$

but

$$f = \frac{B_h}{M_h} = \frac{B_v}{M_v}$$

$$\therefore \frac{a}{1 + a} = \frac{1}{1 + b} \therefore ab = 1$$

That is, if the channel increases the strength of the girder by one-third, the girder must increase the strength of the channel by 300%, a highly improbable contingency.

Wm. A. Green, A. M. Inst. C. E.,
Asst. Engineer, R. A. Skelton & Co.

London, England.

[We referred the above letter to the Worden-Allen Co., of Chicago, which designed and built the shops in question, and have the following reply—Ed.].

Sir—Relative to the crane-runway girders in the locomotive shop of the Lima Locomotive Corporation, the undersigned is unable to recollect the exact method of fastening the channel to the top flange angle of girders. There were, however, sufficient rivets connecting the channel to the flange angles so that this channel is part of the girder.

Using the same notations as in the above discussion, the equation $F = \frac{B_v}{B_m}$ does not state the exact condition. The moving load passing over the girder will produce a certain deflection, but the stiffness of the channel about a plane parallel to its web being negligible it will deflect the same amount as the girder, producing a stress from the vertical load in addition to a stress from the bending moment from the assumed side thrust. This shows that it is impossible to design a girder which will take care of the side thrust independently of the vertical load.

Were it possible to obtain the above conditions, however, the result of the calculation based upon the assumption that the channel is part of the top flange does show that the increment by which the section modulus of the girder in the vertical plane is increased is equal to the increment by which the section modulus of the top flange in the horizontal plane is increased, a result that cannot be true considering the respective sections and their respective lever arms.

Furthermore, it is questionable if the term $\frac{B_v}{M_v}$ in the calculation dealing with the channel and girder separately is equal to the term $\frac{B_v}{M_v}$ in the calculation dealing with the channel being part of the girder. Considering the channel as part of the girder, the center of gravity will rise up toward the top a certain amount, giving a different section modulus. For this reason it is the opinion of the undersigned that the terms and questions are not equal and hence cannot be interposed from one equation to the other.

It is true that the channel, considered as part of the girder, will increase the girder strength. How much it will increase it, however, has to be determined in each individual case. The above discussion shows the fallacy of the conclusion reached that if the channel increases the strength of the girder by one-third, the girder increases the strength of the channel by 300%.

Frederick Hoffman,
Engineer, Worden-Allen Co.

Commercial National Bank Bldg., Chicago,

NOTES AND QUERIES

The inquiry in this column some weeks ago in regard to the construction of reinforced-concrete cooling ponds has been answered satisfactorily by several engineers. We hope to have a description of one or more such tanks in an early issue.

A Wind-Wrecked Gantry Crane, Marion, N. J.

The wreck of the 150-ton gantry crane at the Marion Generating Station of the Public Service Electric Co., of New Jersey, noted in our issue of last week, is very

Fig. 1. [illegible] End of Crane before Accident

FIG. 2. GENERAL VIEW OF OVERTURNED CRANE

interestingly shown in the accompanying views. The span of the crane was 150 ft. 2¼ in., 43 ft. 1 in. high to upper chord, with wheel bases 27 ft. long. The principal operating features of the crane are shown in Fig. 1 of the tower nearer the station.

The cross structure of the crane carries a belt, which can be supplied with coal from the belt conveyor running parallel with the station. The coal is conveyed on the crane belt to about the center where it is tipped, falling to storage piles. When it is desired to return the coal from the piles to the station, the clam-shell bucket places the coal into the hopper over which it is suspended (Fig. 1). After being crushed it is carried up to the belt on the stationary structure, running parallel to the travel of the crane. The track on which the crane travels is 300 ft. long and is not provided with bumpers at the end.

A high wind on July 23 carried the crane from one end of its track to the other at rapid speed. When it reached the end of the track the forward trucks went off onto the ground, a distance of about 8 ft., where they sank. The crane, of course, fell over in the direction of its motion, not only wrecking itself but also a yard locomotive. The position of the crane after its fall is shown in Fig. 2. Fig. 3 shows the wreckage of the crane and the locomotive. The small views at the right of Fig. 3 show the manner in which the forward wheels sank into the ground after derailment. The bearing cap of one is shown to be broken, leaving the wheel nearly buried.

The crane is damaged beyond repair and it is expected that a new one will be erected in its place. The damage is estimated at $50,000. The crane was furnished ten years ago by the Robins Conveying Belt Co., New York City. It was braked by a locking device on a reduction shaft from the driving motor. It is claimed by the electric company that all driving wheels were locked in this manner at the time of the accident.

(The structural excellence of a locomotive boiler is exhibited in a remarkable manner in the left-hand view.)

Noteworthy Concrete Structures on the Lake Erie & Eastern R.R.

The Lake Erie & Eastern, a six-mile extension of the Pittsburgh & Lake Erie Ry. through the city of Youngstown, O., is a high-level line and includes a large number of bridges and viaducts, some steel and some concrete. Noteworthy innovations in design and construction are found in these structures, as will be seen from the following notes on the concrete structures. The steel structures will be reviewed in a later article.

A location sketch (Fig. 1) of the Lake Erie & Eastern shows the three river crossings and the adjacent viaducts.

FIG. 1. SKETCH MAP OF LAKE ERIE & EASTERN RY.

The line departs from the four-track P. & L. E. line at Struthers (a few miles south of Youngstown), crosses the Mahoning River to the right bank, and ascends on embankment and hillside cut until, opposite the center of Youngstown, it enters on a one-mile stretch of embankment, street-crossing and viaduct construction up to the second bridge over the Mahoning near the city filter plant (Crossing No. 1, in Fig. 1). Thence it cuts through high ground for one-half mile and crosses the river a third time, swinging back to the right bank along the Ohio Works of the Carnegie Steel Co.; here a [illegible]-ft. length of the embankment is made of poured slag, retained along the river bank by a wall laid up of [illegible] slag blocks. Beyond this fill the line crosses the river the fourth (and last) time, and a few hundred feet beyond it crosses over seven railway tracks (Erie, Baltimore & Ohio, Pennsylvania and joint) on a long skew, by means of a long wall structure decked with I-beams bedded in concrete. About a quarter mile farther on is a similar crossing, but over only five tracks and not quite so sharply skewed. The present work terminates with that structure, leaving the line [illegible] ft. above ground.

The location west of this point is not finally decided; it will lead to a connection with the Pennsylvania line at Girard or to another point near Niles Junction.

The line is very costly. Some of the work quantities are: Grading [illegible] cu. yd.; concrete masonry [illegible] cu. yd.; steelwork, [illegible] tons.

The four river bridges are steel truss and plate-girder structures. Some approach viaduct, the railway crossings and all street bridges over the railway are also steel, on concrete piers or walls. The street undercrossings are all concrete arches, however, and wherever viaduct construction was required by right-of-way limitations concrete viaducts were built, except that on the river flats near the filter plant steel viaduct on concrete piers was used in harmony with city water-works requirements.

ARCH-WALL CONCRETE VIADUCT

The concrete viaduct (Figs. 2 and 3 show one portion) is an original and ingenious type of structure. It consists of two longitudinal walls interrupted by arched openings at intervals of 32 ft., which break up the lower part of the wall into piers $9\frac{1}{2}$ ft. long. At each such pier a cross-wall connects and braces the two longitudinal walls, but this cross-wall carries no vertical load other than its own weight. Across the main walls is laid a deck of 15-in. I-beams spaced 18 in. apart c. to c., and these are surrounded by and bedded in a $19\frac{1}{2}$

FIGS. 2 AND 3. ARCH-WALL VIADUCT ON LAKE ERIE & EASTERN RY., NEAR CROSSING OF THE B. & O. R.R., YOUNGSTOWN, OHIO

in. thickness of concrete, which carries a normal ballast-and-tie railway track.

The drawing Fig. 4 shows a typical portion of this viaduct. Dotted lines indicate the horizontal construction joint in the longitudinal walls, by which the walls are divided into (1) piers with curving overhang portions on either side, and (2) a longitudinal girder over these piers, shaped so as to complete the curve of the pier overhang and form a semicircular arch top of the opening between piers. The openings do not represent the structural character of the wall, however; the action is purely that of piers and girders.

In the view Fig. 5 some of the forms for the arch-walls and cross-walls can be seen.

Where the viaduct joins an embankment, the end cross-wall is made very thick—30 in.—and forms a reinforced slab diaphragm between the longitudinal walls to take the earth pressure. There are no wings, however, the earth being allowed to slope down around the concrete structure on its natural slope. Where the viaduct is so high that the toe of the slope may reach the second cross-wall, this (in its lower portion only) is also built heavy to resist earth pressure.

The walls have vertical bars projecting from the top, which bond into the concrete filling of the deck.

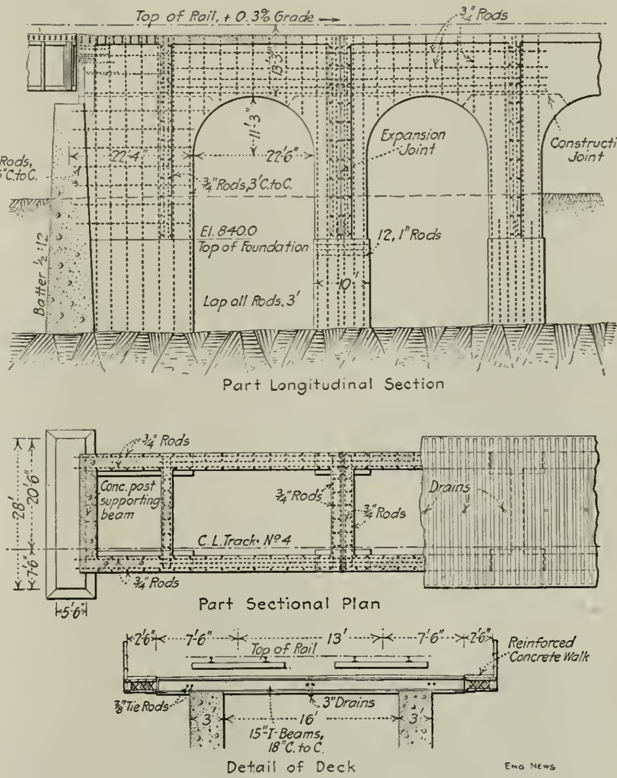

FIG. 4. ARCH-WALL VIADUCT ON LAKE ERIE & EASTERN

SPECIAL CONCRETE-PILE FOUNDATIONS

Concrete piles of a new type are employed as foundation for a considerable length of this concrete viaduct, and also some other viaduct and bridge piers of the line. These piles, described in a recent issue of ENGINEERING NEWS (June 25, 1914, p. 1412), consist of premolded reinforced-concrete inserts set into a hole made by driving a steel casing into the ground, and are grouted into the hole while the casing is pulled. Besides the novelty of the piles, a remarkable feature of these foundations is the high pile-load, 50 tons working load per pile with impact, or about 40 tons without impact.

The piles are 16 in. in diameter, by about 20 ft. long. Test loads of 60 tons produced no permanent settlement that could be measured.

FIG. 5. FORMWORK FOR ARCH-WALL VIADUCT, LAKE ERIE & EASTERN

CONCRETE SKEW ARCHES

The most important of the six concrete arch street-crossings is at Mahoning Ave., Youngstown, with a span of 64 ft. square, or 85½ ft. measured on the skew. The length of barrel, 82 ft. 10 in., is divided into four rings by construction joints parallel to the arch faces, so that the rings necessarily act as skew arches. The drawing Fig. 6 shows this arch.

A skewback construction joint (not shown) was made to stepped outline, with faces of the steps normal to the arch pressure-line. The forms for the abutments were cut to the appropriate stepped outline at the top, and the concrete screeded off, to produce this stepped joint.

These arches are founded on the soil direct, a good gravel stratum being available for a footing some 7 ft. below the surface.

The end faces of the arch, and the showing faces of the wings, were rubbed after removal of forms. The inside of the arch barrel was left as it came from the forms; while it shows the joints of the lagging,

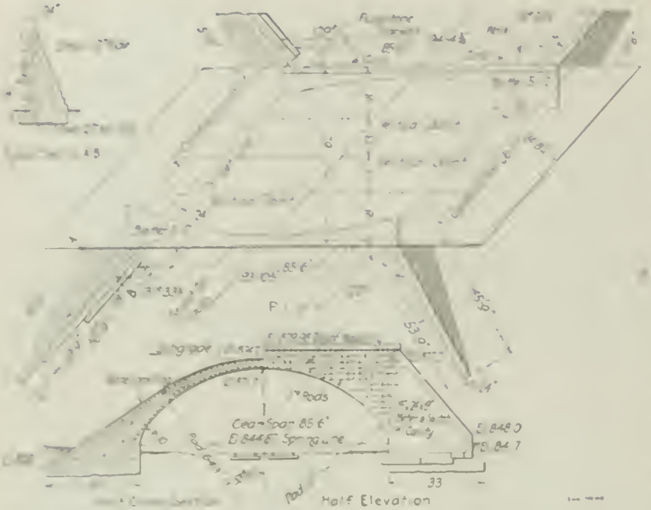

FIG. 6. HEAVY CONCRETE SKEW ARCH, MAHONING AVE. CROSSING OF THE L. E. & E. RY., YOUNGSTOWN, OHIO

the surface is satisfactorily good.

WALL-AND-BEAM CROSSINGS OVER RAILWAY TRACKS

The long skewed 5-track and 7-track railway crossings (Fig. 7) are composed of a deck of transverse plate-girders, closely spaced, carried on longitudinal walls between alternate pairs of tracks. The walls are offset past each other successively, corresponding to the stepped outline of the beam deck (as seen in plan).

The longest of these walls is over 500 ft. in length. The height above ground is 25 ft., and the greatest depth of foundation below ground is 22 ft. The walls go down to rock, but where the depth to rock exceeds 12 ft. the part below ground consists of individual piers 12 ft. long and 12 ft. apart in the clear, the continuous wall beginning just below ground line.

The walls contain both longitudinal

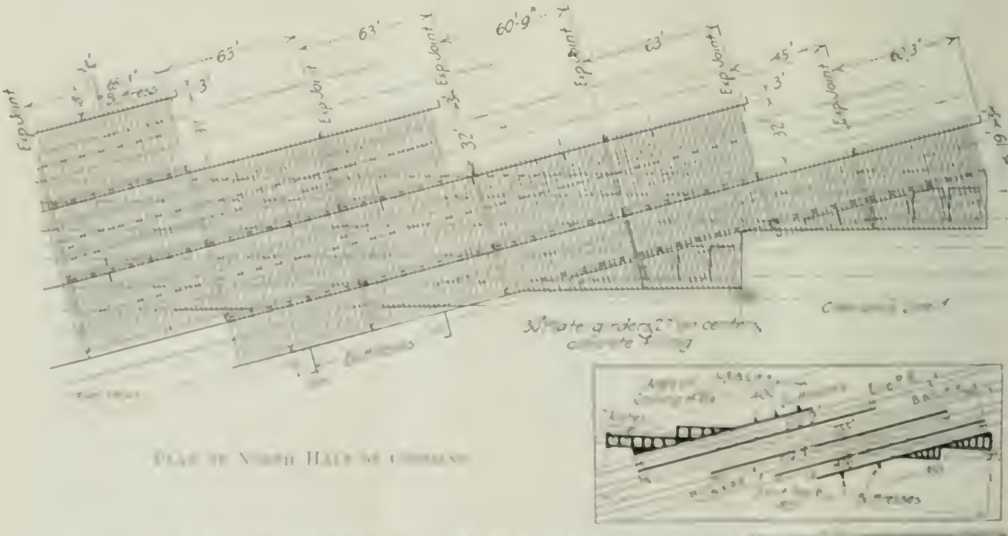

FIG. 7. WALL AND GIRDER CROSSING OF L. E. & E. RY., OVER SEVEN RAILWAY TRACKS AT BRIER HILL STEEL WORKS

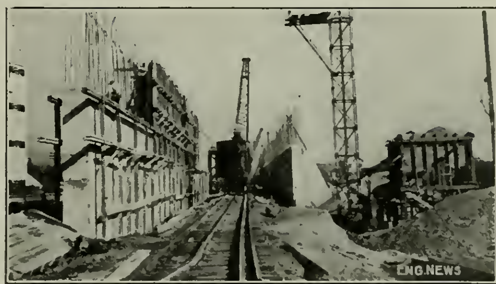

FIGS. 8 AND 9. CROSSING OF LAKE ERIE & EASTERN RY. OVER SEVEN RAILWAY TRACKS, DURING CONSTRUCTION

and vertical reinforcement. They were made in construction sections 45 to 65 ft. long, all steel being interrupted at the joint, for expansion and contraction.

Concreting was done in large part by tower and chute, one set-up being sufficient to cover about 80% of the crossing. The larger of the two crossings, built by the Duquesne Contracting Co., is so spread out that although concrete was chuted over 300 ft. the farther wall could not all be reached in this way. For this portion, the concrete was delivered by the chutes to buckets at ground level, and these hoisted by locomotive crane and dumped into the forms. The other crossing, built by the McKelvy-Hine Co., did not require this expedient.

WARPED-SURFACE RETAINING-WALLS

Some uncommon retaining-walls occur at different points of the line. The walls are all of gravity section, but in a few cases they were built with a base capable of carrying an increased height of wall, for later changes in track arrangement. In such places the wall is in shape the bottom portion of a full-height wall, and the top width is therefore abnormal. No steel bond is provided for the future upper section.

A more special form of wall was used at the southeast abutment wing of the third Mahoning River bridge, making a transition from the normal 1:12 batter of the bridge abutment to the 1:4 batter of the slag river-wall. This wall, Fig. 10, has warped surface both front and back, the back batter changing on account of change in elevation of footing. But the face is not a simple warped surface. At one end the profile of the wall shows an upper vertical portion and below this a 1:12 battered portion; at the other end the batter is continuous 1:4 from top of wall to footing. The face thus consists (in theory) of two warped surfaces tangent at one end of their intersection; in actual construction the shape was produced by bending the lagging to the profile frames, and probably varies from the theoretical surface form.

Less complex warped surfaces occur at other retaining-walls. But most of the walls have stepped back, to take advantage of the weight of the earth backing.

MATERIALS

Slag is used extensively on the Lake Erie & Eastern. Besides its use in poured and block-cast embankment construction, it is used for all sub-ballasting, this being granulated slag.

However, no slag was used in the concrete. Other concrete work in Youngstown frequently employs crushed slag for sand and coarse aggregate—granulated slag is unsuitable—and good results are reported. The railway work however was all built with Pittsburgh sand and gravel from the Ohio River.

ENGINEERS AND CONTRACTORS

The construction work, under J. A. Atwood, Chief Engineer, and A. R. Raymer, Assistant Chief Engineer of the Pittsburgh & Lake Erie Ry., was directed by F. J. Mannah, Assistant Engineer (succeeding E. F. Wendt), with R. T. McMaster in local charge as Resident Engineer. All designs were prepared in the office of A. R. Raymer. Albert Lucius, New York, is the Designing and Consulting Engineer for all steelwork.

The work was divided into three line contracts. The southerly part, which is largely rock excavation and embankment, was carried out by H. A. & R. L. Culbertson. The middle section, of rock excavation and embankment,

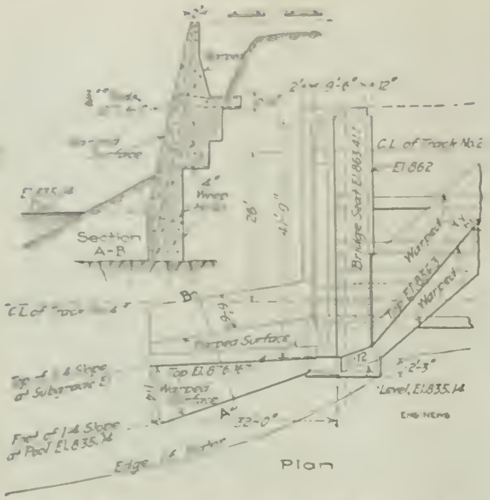

FIG. 10. WARPED-SURFACE RETAINING-WALL AT MAHONING RIVER CROSSING NO. 3, L. E. & E. RY.

and the upper railway crossing, were done by the McKelvy-Hine Co. The concrete structures of the northerly part, and the earth excavation between the second and third river bridges, were done by the Duquesne Contracting Co. The McClintic-Marshall Construction Co. built and erected the steelwork, including the I-beam and plate-girder decking. The concrete filling of the deck is being done by the McKelvy-Hine Co.

All structures are now complete except the lower river bridge (at Struthers) and the concrete filling of the viaduct deck. Embankment has still to be finished at several points, and an earth cut widened as it was taken out only wide enough for a construction track because the material could not be moved to the points where fill was needed until completion of the line.

High-grade track, with screw spikes and four-hole tie-plates carrying 100-lb. rail, is to be used on the line.

The Official Opening of the Cape Cod Canal

After five years of continuous construction work the famous Cape Cod Canal, between Buzzards Bay and Cape Cod Bay on the coast of Massachusetts, was formally opened for the traffic of vessels of 15-ft. draft on Wednesday, July 29. The projected depth of the canal is 25 ft., but the opening for vessels drawing 15 ft. was an event of no small historical significance, since the canal project is about as old as the State of Massachusetts. Its construction was begun and abandoned so many times, and the date set for its final completion changed so frequently, that the Cape Cod natives long ago despaired of witnessing so notable an event as the passing of an excursion steamer carrying several hundred passengers.

The official opening was first announced to take place on July 4, but the ceremony on that date had to be revised to the passing of a boat part way across the waterway by August Belmont, the New York capitalist, who is President of Cape Cod Construction Co. The ceremonies of July 29 were more elaborate. A special train was provided by the canal company from Boston to New Bedford, which brought the Governor of Massachusetts and other notable guests.

At New Bedford, all invited guests were taken on board the "Rose Standish," a Boston excursion steamer, and under an escort of seven United States torpedo-boat destroyers, several private yachts, tugs and other craft, the "Rose Standish" proceeded to the head of Buzzards Bay, the western entrance to the canal. After reaching the entrance to the five-mile channel, which forms the western section of the canal, the naval escort, with the exception of one torpedo-boat destroyer, returned to Buzzards Bay. The official fleet then passed through the canal from west to east, arriving in Cape Cod Bay in about one hour and a half.

About all the native and summer residents of the Cape appeared to have congregated on the banks to welcome the passage of the fleet and the enthusiasm was quite infectious. On arriving in Cape Cod Bay, the fleet was turned about and returned through the canal to the Buzzards Bay entrance, where the party was landed and speeches were made by Governor Walsh, of Massachusetts, August Belmont, of New York City, and others.

Work on the canal was begun by the Cape Cod Construction Co. on June 19, 1909, by placing the first stone on the 3000-ft. breakwater at the eastern entrance on Cape Cod Bay. Most of the excavation was done by dredges working in from both ends. About 800,000 cu. yd. in the central section were removed by steam shovels. By building dams across the channel at each end of the section these shovels were kept at work until the excavation was 15 ft. below sea level.*

The maximum difference in sea level at the two ends of the canal, due to difference in tides in the two bays, amounts to about 8 ft. The current due to this difference was estimated at about 4 mi. per hr., but from all appearances this velocity is greatly exceeded in the present 15-ft. channel. It is evident that all the problems of operation and maintenance are not yet solved; and it may be found necessary to add a tide lock, which was a part of all the early plans for the canal. The swift currents at times of spring and neap tides, like that of July 29, are sure to cause difficulty in navigating barge tows through so narrow a channel (100 ft. at the bottom), as well as the problem of caring for the silt that the swift current is surely going to deposit in the Buzzards Bay approach channel.

The canal is to be operated as a commercial enterprise. Tolls range from $1 for a canoe or row boat up, according to recent press reports.

The engineering staff of the Cape Cod Construction Co. consists of William Barclay Parsons, Chief Engineer, Eugene Klapp, Deputy Chief Engineer; Charles T. Waring, Resident Engineer, and A. S. Ackerman, Senior Assistant Engineer. The contractors were, the Degnon Contracting Co., the Furst-Clark Construction Co., C. W. Reynolds, the E. W. Foley Construction Co., the Pennsylvania Steel Co., the T. A. Scott Co., the Wilson & English Construction Co., and the Holbrook, Cabot & Rollins Corporation.

*A full account of the construction methods on the Cape Cod Canal was given in "Engineering News," Feb. 16, 1911; a historical sketch of the enterprise and a description of the topographical features of the locality were given in "Engineering News," Jan. 4, 1912.

Bridge and Ferry Building by Engineer Corps of Austrian Army*

The accompanying view shows a detachment of the Austrian Engineer Corps engaged in erecting a temporary bridge. Austria maintains no mounted engineers. A unit of three wagons are assigned to each cavalry regiment of 900 sabers. Three classes of bridges can be built with the material in these wagons:

(a) NORMAL BRIDGE—Whole pontoon supports, four balks per bay, three-panel roadway, suitable for the passage of all arms accompanying a cavalry division. Maximum length, [illegible] ft.; width, 7 ft. 10 in.; 15-ft. bays.

(b) HALF [illegible] BRIDGE—Whole pontoon supports, three balks per bay, two-panel roadway, suitable for cavalry in file. Length, [illegible] ft.; width, 5 ft. [illegible] in., 15-ft. bays.

(c) FOOTBRIDGE—Half pontoon supports, two balks per bay, one-panel roadway, for men on foot only; horses swimming below bridge. Length, 162 ft.; width, 2 ft. 7 in.

None of these bridges is very strong. With the normal bridge (the strongest) field guns must be unhitched and moved across by hand. The lighter bridges require that the troops separate from the ammunition, baggage and provisions. Hence the most practical of the three is the normal.

For the crossing of streams, ferryboats are relied upon to a greater extent than bridges. Each unit of three wagons contains parts for two landing stages and a rope ferry of two or three pontoons. The usual ferry consists of three pontoons lashed gunwale to gunwale and decked over. It will carry either:

Six horses and riders;

Two guns and limbers, without horses;

Two field wagons and [illegible] men;

Fifty-five armed men;

Sixty unarmed men.

The passage of a cavalry division across a stream of average size requires from one to two days, depending whether the horses are swum over.

The pontoons are built with steel frames covered with galvanized sheet steel. The bottom is covered by a flooring of strips of planks. They draw, light, about 1½ in. and are thus [illegible]

Length	10 ft. 10 in.
Beam	4 ft. 7 in.
Depth	2 ft. 0 in.
Thickness of skin (about)	0.025 in.
Weight	408 lb.
Displacement	4810 lb.

GERMAN BRIDGE EQUIPAGE

As a comparison with the bridge data given for the Austrian army engineers, it is interesting to note that the German engineers erect much more substantial pontoon bridges. Each regiment of German cavalry (600 sabers) is assigned two pontoon wagons loaded with bridge material and tools and equipment for repair and demolition. The equipage carried with a cavalry division (six regiments) is supposed to be able to build the following bridges:

(a) NORMAL BRIDGE—One whole pontoon to each bay, using saddles, three-panel roadway, 157 ft. 6 in. long, 9 ft. 10 in. wide, able to carry cavalry in file, men leading horses, guns and wagons with two horses.

(b) LIGHT BRIDGE—Half pontoons alternating with pontoons, two-panel roadway, 221 ft. long, 6 ft. 3 in. wide, to take cavalry in file.

AUSTRIAN ENGINEER CORPS BUILDING A PONTOON BRIDGE OVER THE DANUBE RIVER

(c) FOOTBRIDGE—Half pontoons, one-panel roadway, 315 ft. long, [illegible] ft. [illegible] in. wide.

The footbridge has little value as the men must separate from supplies; it vibrates badly and the pontoons act badly even in mild currents. The light bridge is suited to short raids where no artillery is required. The main dependence, however, is placed in the normal bridge.

Partial Failure of Standley Lake Dam, Near Denver, Colo.

(Correspondence)

The Standley Lake Dam, lying about 12 miles northwest of the City of Denver, Colo., has been reported by the daily press within the last few days to be in danger of failure, and an examination was made on Saturday, Aug. 1, 1914, by the State Engineer of Colorado, accompanied by Messrs. A. L. Fellows, W. M. Reynolds, conducted by John E. Hayes, Engineer of The Denver Reservoir Irrigation Co., with a view of ascertaining the extent of the failure, the possibility of further failure, and other matters, and the attendant danger.

The Standley Lake Reservoir was constructed for the most part between the years 1909 and 1911. It consists in the main of an earth embankment 7000 ft. in

*From a Report to the Board of [illegible], Vol. [illegible], [illegible] "Professional Memoirs," March-April 1914.

length, and was constructed to a height of 113 ft. at the lowest place, and tapering to nothing at the two ends of the embankment. It was constructed with slopes, 2 horizontal to 1 vertical, on each side, with two berms on the lower face. The two outlets are of concrete and appear at the present time to be in good condition. The material, which seems to be of rather poor quality, was for the most part placed from dumping cars, run lengthwise of the embankment upon high trestles, and does not appear to have been tamped, rolled or sprinkled or packed in any way, excepting by impact of the falling material. The trestles rest upon lines of piling along and parallel with the axis of the embankment. Settlement in the dam, since construction, has been very large, being apparently some 10% of the height of the dam. Water was impounded in the reservoir in 1913 to a depth of 79 ft. at the outlet, and in 1914 to a depth of 83 ft. The plane of saturation appears to be very flat, but investigations regarding this phase have not as yet been completed.

The upper face of the dam is riprapped with about 2 ft. of large boulders, shaped as broken from the quarry, and roughly laid by dumping. In general, it would not seem to have been very greatly affected by wave action, excepting in a few places, one of these places being opposite to the point where the partial failure has just occurred.

During the last week of July, 1914, a partial failure of the back of the dam near the center of the embankment occurred. About 300 ft. in length of the rear, one-half of the embankment bulged at the lower face to some extent, the line of breakage extending to the inner edge of the crest of the dam. The old line of trestle appears to have been pushed out for a distance of 10 or 15 ft. The management immediately ordered the water to be turned out from the dam, and the water has now been lowered from a depth of 83 ft. to a depth of 76 ft., and will be lowered to a depth of from 65 to 70 ft., at which depth of water there would appear to be no danger of further failure at the present time. Extreme care is being exercised, watchmen being kept constantly at the point of settlement as tremendous damage would be done to cultivated lands, railroads and houses lying below the dam.

The State Engineer, who is giving the matter his personal attention, has issued instructions as to what is to be done at once in connection with the matter. For the present it is safe to say that no damage to property lying below the dam is likely to occur, and the partial failure, while of great interest to the engineering profession, is not likely to result in damage to anyone other than the Denver Reservoir & Irrigation Co.

The Railway Rate Decision

The long expected decision of the Interstate Commerce Commission on the petition of the railways in the territory east of Chicago to advance their freight rates an average of 5% was made public on July 29, but the exciting events in Europe so diverted the attention of the newspapers that comparatively little publicity has been given to the decision. This is unfortunate, as it is one of the most important decisions ever handed down by the Commission. It is a lengthy document of over 100 pages, but its conclusions may be briefly summarized as follows:

The Commission assents to an advance in rates substantially equal to the amount asked for in what is known as Central Freight Association territory, which includes the region west of Buffalo and Pittsburgh, and east of the Mississippi River. The advance in freight rates are refused to the lines east of Pittsburgh and Buffalo. Commissioners McChord and Daniels filed dissenting opinions.

The Commission agrees that the railways have established that in many cases they are entitled to earn larger net profits from their business than they are now receiving. The Commission holds, however, that the way to secure these net profits is not by a horizontal increase in all freight rates but that the rates should be placed on a more just and scientific basis. Instead of advancing all rates, the rates should be advanced on those classes of traffic which are now clearly unremunerative.

The Commission further points out that the chief cause of deficient profits in the railway business is that passenger traffic is being carried at too low rates. It urges that steps be taken to separate passenger expenses from freight expenses in railway accounting, and expresses the belief that if the two-cent-a-mile laws are shown to be unjust to the railways, the public will acquiesce in amendment of these laws so that fares may be increased to a remunerative basis. The Commission further proposes that the railways investigate the expenses they now incur in furnishing various classes of free service in connection with freight shipment, together with the cost of soliciting freight and passenger traffic. The Commission finds that on 88 railways the expense of soliciting business in the year ending June 30, 1913, was $4,298,000.

Among other suggestions of the Commission as to the methods by which the railways can increase their revenues are a further reduction in the issue of passes, a study of methods for increasing freight-car efficiency, and methods of economizing in fuel and in other large items in operating expenses.

Two other suggestions of the Commission which point very closely to the recent revelations in connection with the New Haven system and the St. Louis & San Francisco are, first, the proposition that railways should sell all the properties they now hold that they cannot use for transportation purposes. The railways in the territory to which the report refers have invested more than $684,000,000 in such property, and about one-fourth of this investment returned no income whatever last year. The second suggestion is as follows:

> We suggest that an investigation be made with a view to determining to what extent the cost of construction or of acquiring properties or capital or of operation is being increased through the holding by directors, officers or employees of interests with other concerns with which the carrier has dealings.

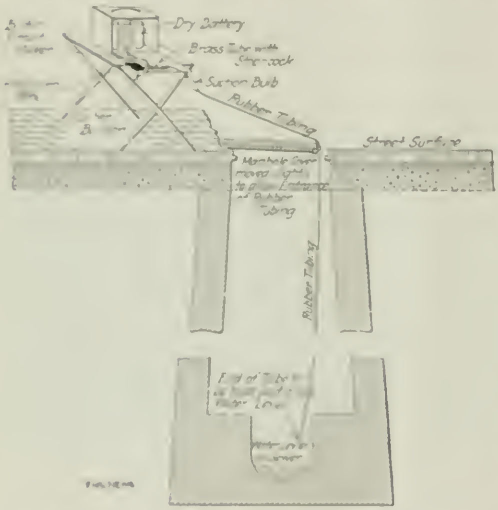
The plain intimation here is that the operating expenses of railways are being increased in some cases through the existence of graft in connection with the purchase of supplies or the acquirement of property. That there is some ground for this assertion recent investigations have proved. The Commission announces that it is itself conducting an independent investigation of this matter.

The most important point in the whole decision is the explicit recognition of the Commission that the railways are entitled to charge rates high enough to earn a fair return on the capital invested, provided, of course that the properties are honestly and efficiently managed.

It is doubtful, whether there will be another petition for a general horizontal advance in rates. In view of the opinion of the Commission now given, the problem of increasing rates must be solved by attacking the matter in detail and by following out to a considerable extent, where practicable, the suggestions of the Commission.

Simple Apparatus for Testing Sewer Air for Explosive Mixtures*

Experiments made by Prof. A. L. Dean, of Yale University, have proved that an explosive mixture may



APPARATUS FOR TESTING SEWER AIR FOR EXPLOSIVE MIXTURES, DEVISED BY PROF. A. L. DEAN, YALE UNIVERSITY

be made of only one part of gasoline to 15,000 parts of air by volume; or 1 gal. of gasoline to 2000 cu. ft. of air. This shows how small an amount of gasoline in a sewer may cause serious damage if ignited.

Prof. Dean has designed a simple, ingenious and apparently practical device for testing the air in sewers, without sending a man into the sewer to obtain a sample of the air. This apparatus is shown in the accompanying sketch. The apparatus is to detect gasoline vapors, which are heavier than air; lighter illuminating gas may be detected by odor at the top of the manhole, although the apparatus will show if there is enough to form an explosive mixture.

A long rubber tube is let down into the manhole, through a small opening left by just starting off the cover, after sounding for depth to find the length of tube necessary to reach nearly to the surface of the sewage. The bulb is worked until both the rubber tube and bulb are filled with sewer air. Then a small, collapsed rubber toy-balloon is slipped over the firing end of the short piece of brass tubing, to which the long rubber suction tube is attached.

Projecting from the brass tube into the balloon are the ends of two insulated wires from the dry-battery cells, the wire ends being connected by a fine platinum wire. When the balloon is well filled with sewer air by pumping with the bulb, the stop-cock in the brass tube is shut, to prevent backfiring, and the electric circuit is closed by pressing a button. The heated platinum wire explodes the balloon if the sewer air is of an explosive mixture.

*Abstracted from a recent report by Henry J. Kellogg, [illegible] City Engineer, New Haven, Conn., on "Explosions in Sewers."

Analyses of Tubercles from the Interior of a Cast-Iron Water Main*

Samples of tubercles from the cast-iron pipe which enters the High Hill Reservoir gatehouse of the New Bedford, Mass., water-works, were collected and analyses of the soft central or middle portion thereof and of the tubercles as a whole were made. Results of these analyses are as follows:

ANALYSES OF TUBERCLES—Sample marked No. 3, soft central portion of tubercles from 48-in. cast-iron pipe:

Silica and insoluble matter	3.24
Ferric oxide Fe_2O_3	69.12
Alumina and lime Al_2O_3 and CaO	Traces
Sulphuric anhydride SO_3	1.36
Water of hydration H_2O	26.28
Carbon dioxide CO_2	None

Sample marked No. 4, whole tubercle from 48-in. cast-iron pipe as above:

Silica and insoluble matter	1.7[illegible]
Ferric oxide Fe_2O_3	68.62
Alumina and lime Al_2O_3 and CaO	Traces
Sulphuric anhydride SO_3	1.65
Water of hydration H_2O	28.16
Carbon dioxide, CO_2	None

The accompanying illustrations show photographs of some of these tubercles, removed during the inspection of the pipe in May, 1913. The same pipe was inspected five years previously, in May, 1908. During that period, the tubercles had grown considerably in size. The extent of this growth is best indicated by the four outer rings, which can be clearly seen in the illustrations, showing the under or contact side of the tubercle.

*From recent annual report of the Water Board of New Bedford, Mass.

NEWS NOTES

A Broken 20-In. Water Main in New York City flooded the subway excavation on 7th Ave. at 33d St. at 1 p.m., Aug. 3.

An Auto Truck Wrecked a Timber Bridge over the Pennsylvania Canal near Merrlesville, Penn., on July 29.

An Explosion in a Cable Manhole of the Edison Electric Illuminating Co., of Boston, on July 27, blew off the manhole cover.

A Water-Supply Standpipe Collapsed [illegible] in [illegible], Ill., on July 18, flooding adjacent streets. The standpipe was full at the time.

The Flooring of a One-Deck Porch built near the ground collapsed while crowded during a thunderstorm, on July 29, at Keyport, N. J.

The Effects of European War are seen in the recent decision of the Southern Power Co., and the Piedmont & Northern Ry. Co. (allied), not to let the contracts announced for July 5, and amounting to several hundred thousand dollars. It is reported that the plans for a fourth auxiliary steam plant (10,000 hp.) will be held up, although some contracts have been let.

Projects of the city of New York to the extent of $50,000,000 are reported indefinitely postponed. This includes the New York County court house ($20,000,000), the Kings County court house ($2,500,000), the South Brooklyn marginal freight railway ($12,000,000), and various other improvements. While general retrenchment is planned, it is announced that rapid-transit subway and dock-improvement work under way will be carried forward with as little interference as possible.

A Sewer Explosion at 23d St. and Seventh Ave., New York City, on July 27, hurled a manhole cover into the air and sent a column of flame upward. A section of wood-block pavement was ripped up. Sand was used to extinguish the fire in the sewer.

A Locomotive Boiler Exploded on the Erie R.R., near Corning, N. Y., killing the engineer and fireman and injuring another man, on July 31. At about the same time, a tube blowout occurred on an Erie locomotive at Montclair, N. J., injuring the engineer and fireman.

A Cloudburst Flooded Telluride, Colo., on July 27. In the business district, 120 stores were sunk in 8 to 20 ft. of mud; many residences were wrecked. The town is situated in a canon. A dam which retains the water supply for the town was destroyed. Two persons were killed.

Ten Large Forest Fires were reported on July 27 in western Montana and northern Idaho. One of the fires, which was started by campers near the Hearst Lake reservoir, which furnishes Anaconda, Mont., with water, heavily damaged the timber area to the west of the lake.

A Construction Elevator Collapsed at the three-story extension to the Dixmont Hospital, Pittsburgh, Penn., recently, injuring seven workmen. The contractor stated that the men had no right on the hoist and had been instructed to keep off. The fall was claimed to have been not over 14 ft.

The "Incemore" Was Held Responsible for the collision, on June 17, with the North German Lloyd steamship "Kaiser Wilhelm II," by the British Admiralty Court, on July 17. Sir Bargrave Deane in rendering his decision said he found that the "Incemore" had made a mistake in giving a signal that she had stopped when as a matter of fact she had not done so.

A Tow-Barge Demolished a Steel Bridge Span of the Dover bridge over the Choptank River, about 4 mi. from Easton, Md., on July 17. The tug "Rescue," of Baltimore, with two barges in tow, loaded with stone, and bound for a wharf above the bridge, attempted to pass through the open draw, on a strong flood tide. One of the barges struck the bridge, breaking off a number of wood piles, which caused a 70-ft. steel span to drop in 40 ft. of water.

A Gate Accident on the Welland Canal, in which the two headgates of Lock No. 8, St. Catherines, Ont., were carried away by the steamer "Sarnor," of the Lake Erie & Quebec Transportation Co., of Montreal, while upbound to Ashtabula for coal, at about 10:45 a.m., on July 27, delayed navigation for about 10 hours. The rush of water carried the vessel and the gates out into the reach below. The level above No. 8 is short, while the level below is a mile long, consequently practically no water overflowed and there was no washing away of the banks. It will be necessary to place two spare gates before navigation can proceed. The damage is estimated at about $4000. The accident was caused by the engineer putting the vessel ahead in response to a signal to reverse the engines. A 1¼-in. cable was snapped before the gates were struck.

Retired Municipal Employees to the number of about 8000 drew pensions from New York City last year, the total amount of money paid out in pensions being about $4,000,000. The size of the pensions varied all the way from $50 to $6000.

A New Proposal for the acquisition of the Spring Valley water system has been reported made by the city of San Francisco. The City Advisory Water Committee proposes purchase at $34,000,000, the company keeping the larger part of its Pleasanton lands, but giving the right to draw unreservedly on the subterranean waters, and holding its Lake Merced lands except for a marginal strip sufficient to prevent pollution. The company also would be reimbursed for outlay on Calaveras dam. Settlement of the Spring Valley rate case is included.

The Installation of Automatic Sprinklers for fire protection may be compelled by the Fire Department of New York City, according to a decision of the New York Court of Appeals. A property owner refused to install a sprinkler system in his loft building when ordered to do so by the Fire Commissioner. The case was carried to the Court of Appeals, which has affirmed the decisions of the lower courts, sustaining the authority of the Fire Commissioner to order such protective devices installed. It is stated that over 100 orders for the compulsory introduction of sprinklers in New York were on file awaiting the decision in this case.

The McClintic-Marshall Claim on the Panama Lock Gates has been referred by Congress to Col. George W. Goethals, Governor of the Canal Zone, for investigation. Colonel Goethals is to report his findings in detail to Congress. As noted in "Engineering News," Mar. 26 and Apr. 9, 1914, pp. 704, 806, the McClintic-Marshall Construction Co., of Pittsburgh, Penn., who built and erected the steel lock gates for the Panama Canal, recently presented to Congress a bill for extras on this work, amounting to about $2,400,000. Its principal claim was that a grade of workmanship had been enforced in the inspection that was far more costly to execute than the workmanship described in the specifications, and that went beyond any demands of efficiency.

New Mole for San Francisco Bay—A contract for the construction of a mole to replace the trestle now being used by the Key Route System, in San Francisco Bay, was awarded on July 27 to the San Francisco Bridge Co., for an estimated price of $475,000. When this work is completed, the mole will be 100 ft. wide and 11,000 ft. long. There are 1,100,000 sq.ft. of surface to be filled in to a height of 6 ft. above high tide. The average depth is 18 ft. At the end of the land mole there will be a wharf, set on creosoted piles, which will extend an additional 4200 ft. out into the bay toward San Francisco. The company sought the right to fill in under this wharf, but the United States authorities denied them the privilege. The company will make the entire stretch a stone and earthen fill as soon as authority from the government can be obtained.

Automatic Block Signals on the Pennsylvania R.R.—On Sept 1, with the completion of an elaborate plan of improvements in its automatic block-signal system, the Pennsylvania R.R. will have more four-track line operated under automatic signals than any other railroad in the world. At a cost of $6,000,000 in the past three years, 253 miles of main lines have been equipped. By Sept. 1, the main line between Pittsburgh and New York and Philadelphia and Washington will be equipped. The signal system on this road, east of Pittsburgh and Erie, represents an estimated investment of approximately $18,000,000, of which $1,750,000 is in the electro-pneumatic interlocking switch and signal system in the New York station and on the electric line between Sunnyside Yard, L. I., and Manhattan Transfer, N. J. It takes a normal force of 1800 men to maintain the road's signals and it costs $1,500,000 a year.

Fast Trains on English Railways have been reviewed in the engineering supplement of the London "Times," with lists of the various fast schedule runs. Of 62 runs from London, the highest record is 59.4 m.p.h. for 107 miles. The lowest is 36.2 m.p.h. for 730 miles, part of this being over unfavorable lines in the Highlands of Scotland. There are 21 of 45 to 50 m.p.h., 27 of 50 to 55 m.p.h., and 14 of 55 to 60 m.p.h. The three longest nonstop runs were from London to Plymouth (Great Western Ry.), 226 mi. at 54.8 m.p.h.; to Rhyl (London & Northwestern Ry.), 209½ miles at 52.7 m.p.h., and to Shipley (Midland Ry.), 206 mi. at 50.4 m.p.h. There were nine nonstop runs of over 100 miles. The fastest runs, however, were not from London; Darlington to York (Northeastern Ry., 44¼ miles), 61.7 m.p.h.; Leicester to Nottingham (Great Central Ry., 22½ mi.), 61.3 m.p.h. The following table is a list of the 14 fastest runs from London in 1913:

City	Railway	Miles	Time Hr.	Time Min.	Speed
Bath	Gt. Western	107	1	48	59.4
Bristol	Gt. Western	118½	2	00	59.1
Exeter	Gt. Western	174	3	00	57.8
Oxford	Gt. Western	63½	1	7	56.8
Leicester	Gt. Central	103	1	49	56.7
Leicester	Midland	99¼	1	45	56.5
Birmingham	London & N. W.	113	2	00	56.5
Nottingham	Midland	123¼	2	12	56.1
Worcester	Gt. Western	120½	2	9	56.0
Sheffield	Gt. Central	164¾	2	57	55.8
Liverpool	London & N. W.	192¼	3	28	55.4
Birmingham	Gt. Western	110½	2	00	55.2
Salisbury	London & S. W.	83½	1	31	55.1
Plymouth	Gt. Western	225¾	4	7	54.8

Bridge Building Prosperity in Iowa—Iowa counties have let a million dollars' worth of bridge contracts since Jan. 1. They will let contracts for probably half a million more before the end of the year. These figures cover only the work which has been contracted at public lettings. They do not cover the small work that has been let privately. They do not cover any part of the bridges and culverts the 99 coun-

[illegible] are [illegible] Engineers in close touch with [illegible] that the day labor work and the small private contract work will total at least [illegible] for the first half year. In 42 counties no public lettings have been held. These counties are either doing all their work by the day labor system or are completing work contracted for last year. Several counties have held two lettings and [illegible] —From the July "Service Bulletin" of the Iowa State Highway Commission.]

PERSONALS

Mr. Thomas Turnbull, M. Can. Soc. C. E., of Winnipeg, Man., has been appointed Assistant Chief Engineer of the Canadian Northern Ry.

Mr. W. K. Winterhalter, of the firm of Berry & Winterhalter, Consulting Engineers and Agriculturists, San Francisco, Calif., has been appointed Consulting Agriculturist of the Spreckels Sugar Co., San Francisco.

Mr. C. R. Hubbard has resigned as President and General Manager of the Wheeling Steel & Iron Co., Wheeling, W. Va., in order to retire from active business. He has been the managing head of the company since 1892.

Prof. R. K. Chandler, Dean of the engineering division of the [illegible] Agricultural and Mechanical College, has resigned his position to become Head of the Mechanical Engineering Department at the New Hampshire College, Durham, N. H.

Mr. Samuel S. Webber, M. Am. Soc. M. E., has resigned as Chief Engineer of the Trenton, N. J., plant of the American Steel & Wire Co. Mr. Webber was connected with the Trenton Iron Co. before it became a part of the American Steel & Wire Co.

Mr. John L. Billard, of Meriden, Conn., widely known for his connection with the transactions by which the Boston & Maine R.R. was acquired by the New York, New Haven & Hartford R.R., has resigned as Director of the New York, New Haven & Hartford R.R. and the New England Navigation Co.

Prof. [illegible] H. Danforth, for the past six years with the U. S. Naval Experiment Station and the post graduate department of engineering of the U. S. Naval Academy, has been appointed Professor of hydraulics and mechanics at Case School of Applied Science, Cleveland, Ohio.

Mr. Charles E. Brown, Assoc. M. Am. Soc. C. E., for the past six years with the U. S. War Department in local charge of the construction of the Colbert Shoals Canal, Tennessee River, has been appointed Assistant Field Engineer, Division of Valuation, Interstate Commerce Commission, Southern District, with headquarters at Chattanooga, Tenn.

Mr. A. [illegible] Ackerman, Assoc. M. Am. Soc. C. E., Senior Assistant Engineer, Cape Cod Construction Co., builders of the Cape Cod Canal, has been promoted to be Resident Engineer, succeeding Mr. Charles T. Worthy, Assoc. M. Am. Soc. C. E., who has been appointed Superintendent of [illegible] Mr. Ackerman was educated at the Massachusetts Institute of Technology and has been on the Cape Cod Canal work for several years.

Mr. Charles T. Worthy, Assoc. M. Am. Soc. C. E., resident engineer in charge of construction of the Cape Cod Canal, has been appointed Superintendent of [illegible] of the canal, with headquarters at [illegible], Mass. Mr. Worthy succeeds Mr. H. W. [illegible], M. Am. Soc. C. E., now Chief Engineer of the Bureau of Highways, Borough of Manhattan, New York City. In 1911 [illegible] he was Division Engineer of the canal. The Chief Engineer is Mr. William Barclay Parsons, M. Am. Soc. C. E., consulting engineer, New York City.

OBITUARY

[illegible]

[illegible] served three years during the Civil War. Following the war he went into railway bridge work. Later he was Roadmaster of the Connecticut division of the Boston & Maine R.R., which position he held for nearly 21 years. He joined the staff of the Rail Joint Co. of America in 1897 and traveled extensively for the company for many years.

Dr. John Galbraith, Past-President, Can. Soc. C. E., Dean of the faculty of applied science and engineering at Toronto University, Toronto, Ont., died July 22, at his summer home on Georgian Bay. He was born in Montreal in 1846 and graduated at Toronto University in 1868. After graduating, he engaged in railway work, and in 1878 became Professor of engineering in the Ontario School of Practical Science, of which he was appointed Principal. In the early days of that institution, Dean Galbraith taught all the branches of engineering himself, and in the face of great difficulties succeeded in building up the school to the position it at present occupies. When it became affiliated with the university, Dr. Galbraith was appointed Dean of the faculty of applied science. He was one of the three commissioners appointed to investigate the collapse of the Quebec Bridge in 1907. Dr. Galbraith was one of the founders of the Canadian Society of Civil Engineers, and in 1908 was elected President of the society. Among other honorary positions which he held were the Vice-Presidency of the Engineering Section of the British Association for the Advancement of Science and the Vice-Presidency of the Engineering Section of the American Association for the Advancement of Science. [A more complete biography and a portrait of Dr. Galbraith were published in "Engineering News" of Feb. 6, 1908, at the time of his election to the presidency of the Canadian Society of Civil Engineers.]

ENGINEERING SOCIETIES

COMING MEETINGS

AMERICAN ASSOCIATION OF RAILROAD SUPERINTENDENTS.
Aug. 20-21. Annual meeting in New York City. Secy., F. H. Harman, Room 101, Union Station, St. Louis, Mo.

AMERICAN PEAT SOCIETY.
Aug. 20-22. Annual meeting at Duluth, Minn. Secy., Julius Bordollo, 17 Battery Place, New York City.

AMERICAN BOILER MANUFACTURERS' ASSOCIATION.
Sept. 1-4. Annual convention in New York City. Secy., J. D. Farasey, E. 37th St. and Erie Ry., Cleveland, Ohio.

AMERICAN MINE SAFETY ASSOCIATION.
Sept. 7-10. Annual meeting in New York City. Secy., H. M. Wilson, Bureau of Mines, Pittsburgh, Penn.

NATIONAL ASSOCIATION OF PORT AUTHORITIES.
Sept. 8-10. Annual convention in [illegible], Md. Secy., Wm. Joshua Barney, 24 Broadway, New York City.

ROADMASTERS' AND MAINTENANCE OF WAY ASSOCIATION OF AMERICA.
Sept. 8-11. Annual meeting at Chicago, Ill. Secy., L. C. Ryan, Sterling, Ill.

MASTER CAR AND LOCOMOTIVE PAINTERS' ASSOCIATION.
Sept. 8-11. Annual convention in Nashville, Tenn. Secy., A. P. Dane, Reading, Mass.

NEW ENGLAND WATER WORKS ASSOCIATION.
Sept. 9-11. Annual convention in [illegible], Mass. Secy., Willard Kent, Narragansett Pier, R. I.

INTERNATIONAL ASSOCIATION OF MUNICIPAL ELECTRICIANS.
Sept. [illegible]. Convention in Atlantic City, N. J. Secy., Clarence W. Pike, Electrical Bureau, Philadelphia, Penn.

ILLUMINATING ENGINEERING SOCIETY.
Sept. 21-24. Annual convention in Cleveland, Ohio. Secy., Joseph D. Israel, 29 W. 39th St., New York City.

RAILWAY SIGNAL ASSOCIATION.
Sept. 22-24. Annual meeting in [illegible], N. Y. Secy., C. C. Rosenberg, Times Building, Bethlehem, Penn.

American Society of Agricultural Engineers—[illegible] meeting of the Society will be held in Madison, Wis., [illegible]. The preliminary program has not been issued. The Secretary is F. M. White, Madison, Wis.

National Paving Brick Manufacturers' Association—The [illegible] annual meeting will be held at Buffalo, N. Y., Sept. [illegible], with headquarters at the [illegible] Hotel. The business meeting will be held on the morning [illegible] and [illegible] sessions will be held on "A Study of Brick Pavement Construction for Country Highways". [illegible] The Assistant Secretary is H. H. Macdonald, [illegible], Cleveland, Ohio.

American Public Health Association—The annual meeting of the Association will be held in Jacksonville, Fla., Nov. 30-Dec. 4. The secretary is Prof. S. M. Gunn, 755 Boylston St., Boston, Mass.

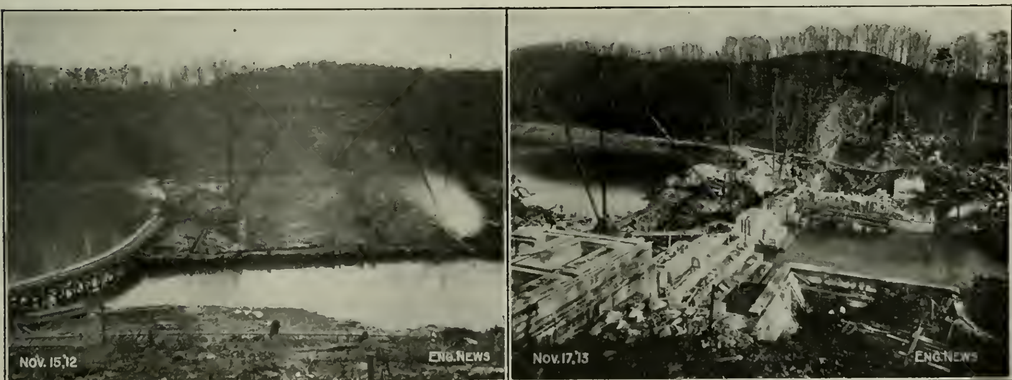
VOLUME 72 AUGUST 13, 1914 NUMBER 7

The New Loch Raven Dam at Baltimore, Md.

By Ezra B. Whitman*

The new Loch Raven Dam, which is being built for the purpose of augmenting the watei supply of Baltimore, is rapidly nearly completion. The necessity for the increased supply was recognized about ten years ago by Alfred M. Quick, who was then Water Engineer, and he proposed building a large impounding reservoir in the valley of the Gunpowder River. In 1908 the State Legislature passed an Enabling Act appropriating $5,000,000 for the purpose of making this improvement in the city's supply. This loan was ratified by the vote of the people in the fall of the same year.



Figs. 1-2. Loch Raven Dam for Water Supply of Baltimore, Md., in November, 1912, and November, 1913

Before proceeding with the construction of the dam in the valley of the Gunpowder, however, the city administration decided to call in outside experts, and John R. Freeman and Frederick P. Stearns were called upon to go over the entire question of improving the water supply for Baltimore. These gentlemen, after a most careful and thorough investigation, submitted a report on March 25, 1910, in which they recommended that the water supply be increased in practically the same manner as that recommended by Mr. Quick, viz., by building a large impounding reservoir in the valley of the Gunpowder River and by the building of a filtration plant.

Present Sources of Supply.

At the present time Baltimore takes its water from two sources. The main source of supply is from the Gunpowder River, which has a drainage area of 308 sq. miles above the existing dam. This dam is built of stone and is about 25 ft. in height above the bed of the river and is located about seven miles northeast of the city limits. The reservoir created by this dam is known as Loch Raven and originally had a capacity of 510 million gallons. This capacity has been greatly reduced by deposits of silt since the dam was completed in 1881. This long, narrow reservoir, extending between two high hills for a length of four miles, is now filled to such an extent that it has but little larger cross section than the normal cross-section of the river. By 1900 the capacity of the reservoir was only 78 million gallons, although dredging had been carried on from 1896 to 1900.

In 1900 the city purchased a suction dredge, which was operated continuously until the fall of 1911, the mud from the bottom of the reservoir being pumped through a long pipe line to a point below the old dam. This dredging increased the capacity of Loch Raven from 78 million gallons to about 178 million gallons. It is calculated that the annual deposit of silt from 1881 to 1909 was 226,000 cu.yd.

The annual yield of the Gunpowder River, according to records kept by the Water Department for the past 27 years, has averaged about 280 million gallons per day. The minimum flow of the stream, however, has been as low as 55 million gallons per day. The present water consumption of Baltimore is about 75 million gallons per day. From these figures it can be seen that if sufficient storage is obtained to store the waters, which at the present time passes over the dam during rainy periods, the stream flow of the Gunpowder River is sufficient to supply Baltimore with water for a number of years in the future. It is for the purpose of supplying this storage

*Formerly Water Engineer, City of Baltimore; now of Greiner & Whitman, Consulting Engineers, Baltimore, Md.

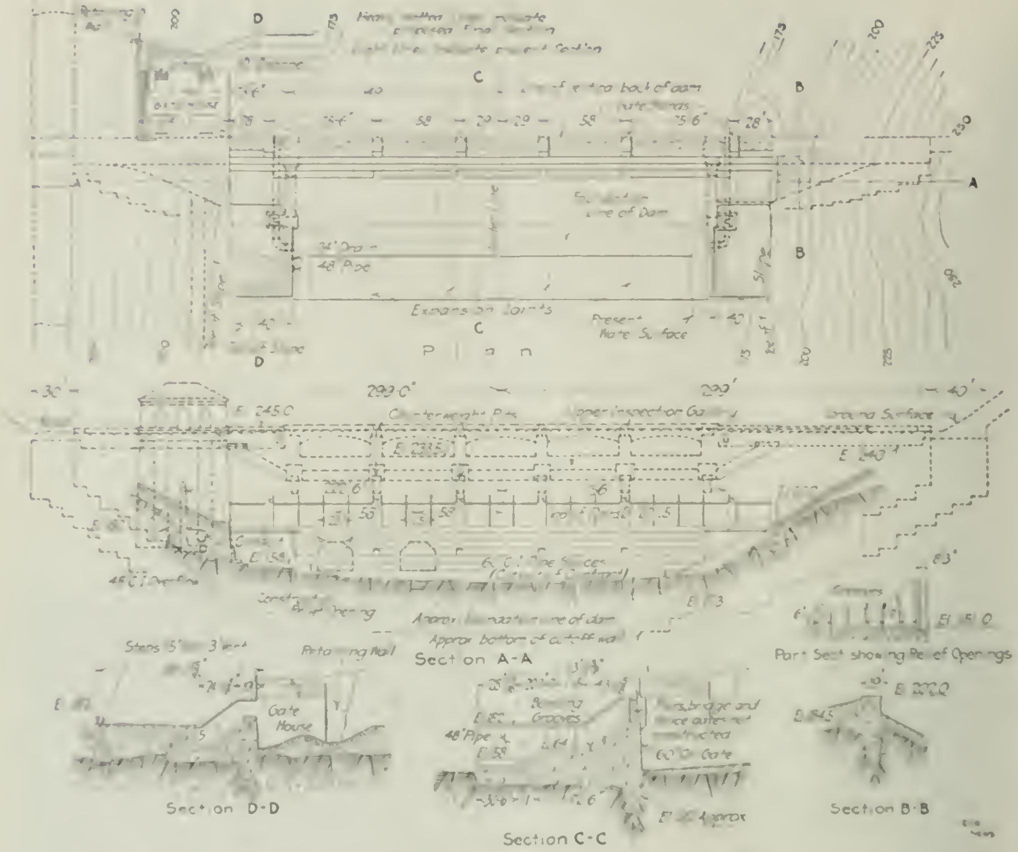


Fig. 3. Details of Construction of New Loch Raven Dam, Baltimore, Md.

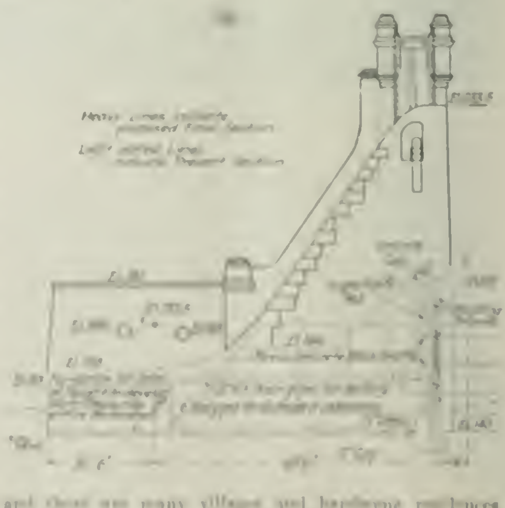
(Upper drawing shows present section with final proposed section dotted; lower drawing shows final section with present section dotted.)

that the new dam at Loch Raven is being constructed.

From the gate house at the old dam at Loch Raven a tunnel seven miles long and 12 ft. in diameter leads to Lake Montebello, just within the city limits. This lake has a capacity of 436 million gallons and is connected by a 12-ft. tunnel with Lake Clifton, which has a capacity of 290 million gallons.

The second source of supply for the city is from Jones' Falls at Lake Roland. Jones' Falls has a drainage area above the Lake Roland Dam of about 30 sq. miles, and it was first used as a source of the city's supply about 50 years ago. Lake Roland is about five miles north of the city. The original capacity of Lake Roland was 500 million gallons of water. This capacity has been largely reduced by deposits of silt, but by means of dredging its present capacity is about 300 million gallons.

The population of the Jones' Falls watershed is over 150 persons per square mile and is increasing very rapidly. The stream flows through the Green Spring Valley, which has become a fashionable suburb of the city,



and there are many villages and handsome residences springing up in this valley. In addition to the pollution from the Green Spring Valley, two of the largest towns

in Baltimore County, Towson and Lutherville, are located on streams emptying into Lake Roland, after flowing only a few miles. The sanitary condition of this source of supply is rapidly becoming a menace to the city, but it cannot be completely abandoned until the new dam is completed at Loch Raven. The average daily yield of the Jones' Falls watershed is about 35 million gallons of water per day.

A masonry aqueduct 5 ft. wide, 6 ft. 4 in. high and about four miles long leads from Lake Roland to the Hampden Reservoir, which has a capacity of about 49 million gallons. Hampden Reservoir is connected with Druid Lake by cast-iron pipes, and Druid Lake has a capacity of about 428 million gallons.

During periods of heavy rain, when the Jones' Falls or Gunpowder River are in a very turbid condition, the gates at Lake Roland and Loch Raven are closed and the muddy water is allowed to go to waste, while the city is furnished with clear water from the storage lakes at Montebello and Clifton from the Gunpowder supply and at Hampden and Druid lakes from the Jones' Falls supply.

It can be readily seen that this method of bypassing the muddy water makes it impossible to make use of the greater part of the run-off of the quick thunder showers falling in the summer time, and it has often been necessary to draw down on the available storage supply in the city limits at a time whe nthe stream flow has been very low. This condition of affairs, however, has been remedied to some extent by the use of alum to settle the turbid waters in Lakes Montebello and Hampden. Before the introduction of the use of alum it had been necessary on several occasions to turn very muddy and turbid water into the city mains, very much to the disgust of the entire population of the city.

Capacity of New Dam.

A careful survey was made of the valley of the Gunpowder River for a distance of 10 miles above the old dam, from which it was possible to compute the capacities of reservoirs behind dams with variable crest elevations, and Table I shows the available storage and other data for dams built to various crest elevations:

TABLE I

Contour elevation	Area, acres	Capacity between contours, million gal.	Total capacity below contours, million gal.
320	11,350	64,863	190,956
300	8,557	48,756	126,093
280	6,407	18,466	77,337
270	4,928	14,508	58,871
260	3,977	11,642	44,363
250	3,169	9,059	32,721
240	2,391	3,695	23,662
235	2,144	3,253	19,967
230	1,866	5,343	16,714
220	1,442	4,116	11,371
210	1,116	3,131	7,255
200	770	2,166	4,124
190	489	1,323	1,958
180	211	458	635
170	97	177	177
158	....	....	.....

Messrs. Stearns & Freeman, from the stream-flow records of the department, computed Table II, showing the amount of storage that would have been required to supply from the Gunpowder River different daily quantities of water throughout the greatest droughts of 27 years prior to 1910. They first reduced, however, the stream-flow records on an average of 6% from the quantity shown by the departmental records in order to allow for obstructions on the spillway and for a different formula for computing the flow over the dam:

TABLE II

Average daily water consumption. (Million gal.)	Available storage capacity required. (Billion gal.)	Storage in equivalent inches depth over drainage area of 308 square miles	Length of longest continuous period that reservoir would have been below spillway crest
90	2 3	0.37	
100	3.5	0.56	
110	4.7	0.75	
120	6.2	1.16	1 year 2 months
130	8.6	1.61	1 year 2 months
140	10	1.87	1 year 6 months
150	13	2.44	1 year 7 months
160	16	3.00	1 year 7 months
170	21	3.94	1 year 8 months
180	27	5.06	1 year 10 months
190	38	7.13	3 years 0 months
200	47	8.81	3 years 8 months
210	57	10.7	3 years 10 months
220	66	12.4	3 years 11 months
230	75	14.1	4 years 1 month

Messrs. Stearns & Freeman also prepared Table III after a study of the water consumption of the city for a period of 39 years, and the growth in population of the city, in order to estimate the number of years in the future that the city could safely take it supply from the Gunpowder River:

TABLE III

Year	Years from now	Probable population: Per cent. growth for decade	Probable population: Estimated total	Probable quantity water used per capita per day, gal.	Total quantity of water probably required. Average million gal. per day
1915	5	..	660,000	130	86
1920	10	20	720,000	135	97
1930	20	17.5	850,000	145	123
1940	30	15	980,000	150	147

The crest of the dam can be carried to an elevation of 237 ft. above mean tide without making it necessary to flood the tracks of the Northern Central Ry. near Phoenix, Md., or to flood the town of Cockeysville, Md. To carry the flood line higher than this elevation would have caused a greatly increased expense. It will also be seen from Table I that the dam, with a crest elevation of 237 ft., would give a reservoir with a capacity of about 21 billion gallons. Table II shows that a reservoir with this capacity would give an average daily water consumption of 170 million gallons per day, which is approximately 2½ times the present consumption of the city. This amount of water, it will be seen from Table III, would probably meet the needs of the city until 1950 or later.

Another very important reason for carrying the flow line to this height is that it will make it possible to suply the water from the resulting reservoir by gravity to the filtration plant, which will in turn discharge the water at sufficiently high level to suply the middle service of the city without pumping and furnish a greater water pressure in the low-service district of the city, which is at present fed by gravity from the present Loch Raven Reservoir with a water elevation of 171 ft. A.M.T.

In order to make the greater part of this 21 billion gallons available, however, it will be necessary to build a pumping station to pump the water to the filters before the water falls more than ten feet below the crest of the proposed dam.

Owing to certain legal complications in connection with the purchase of property in the valley of the Gunpowder, it was first decided to build the dam to a crest elevation of only 192 ft., which would give a storage capacity of little over two billion gallons instead of the 21 billion gallons. This dam with a crest elevation of 192 ft., continued with the existing storage reservoirs in

the city, which have an available storage of about $1\frac{1}{2}$ billion gallons, gives a total storage of $3\frac{1}{2}$ billion gallons. This would furnish a safe daily capacity of about 100 million gallons of water.

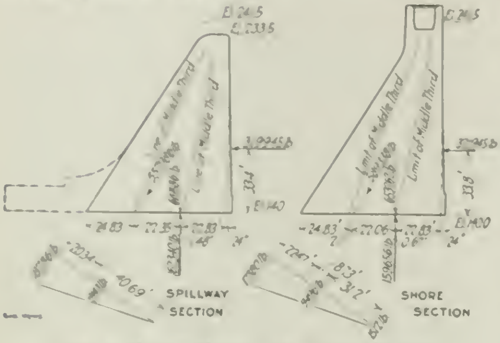


FIG. 4. STRESS SHEET FOR FINAL SECTION

It also developed that it would not be possible to build a dam with a crest elevation of 237 ft. and a filtration plant out of the \$5,000,000 loan available for improving the water supply. The present city administration does not desire to ask for a further loan in order to build the higher dam, as the city is already greatly burdened with loans in carrying out the extensive improvements which have been made since the great Baltimore fire in connection with the new docks, new sewerage system, new street paving for the entire city, extension of the parks and improvement of the fire department and school systems. It has therefore been determined to build a reservoir which will have a crest elevation of 192 ft. at the present time, although the foundations for this dam have been laid of sufficient width, not only to extend the dam to an elevation of 237 ft., but to extend it to a further elevation of 280 ft. if this should be deemed desirable in the future.

DESIGN OF THE DAM

The accompanying diagrams (Figs. 3 and 4) show the sections of the dam which will be required when the crest is raised to an elevation of $233\frac{1}{2}$ ft. It is proposed to secure a water level of $237\frac{1}{2}$ ft. by placing flashboards along the crest. In designing the dam provisions were made for flood water 8 ft. over the top of the masonry of the spillway, and an upward pressure is figured on the horizontal joints and on the bottom of the dam, which is equivalent to two-thirds of the head of water at the upstream face, diminishing to zero at the downstream face of the dam.

The failure of the dam at Austin, Pa., at about the time that the designs for the Loch Raven Dam were being completed emphasized the necessity of taking every precaution to prevent upward pressure under the bottom of the dam and internal stresses within the body of the dam itself, due to water making its way into horizontal joints.

In order to take care of upward pressure under the base of the dam, a system of underdrains has been provided beneath the main foundation and next to the rock. A 12-in. drain with open joints is placed on the downstream side of the cutoff wall along the line of the bottom of the foundation of the dam, as shown on Fig. 5. Connecting to this drain are a number of 6-in. underdrains surrounded by gravel, which rest on the rock foundation, and it is expected that any water which may make its way through the cutoff wall or through the seams of rock on which the dam is built, will enter this drainage system without causing any appreciable upward pressure on the base of the dam.

The 6-in. underdrains are placed at intervals of approximately 30 ft., and they find outlet in risers leading to the top of the foundation apron near its lower end.

The author was familiar with the vertical porous drains used in the construction of the Olive Bridge and Kensico dams in connection with the improvements of the water supply of New York in order to intercept seepage through the body of the dam. It seemed more logical, however, that drains for this purpose should be placed horizontally across the construction joints, where the seepage would most naturally occur.

The upstream side of the dam for a thickness of about 7 ft., as shown on Fig. 3, is built of 1 : 2 : 4 concrete, laid in such manner that horizontal joints occur at vertical intervals of 8 ft. At these horizontal joints on the downstream side of the 1:2:4 concrete wall are laid conduits consisting of porous concrete tile laid in grooves left in this wall. These tiles are 14 in. square, 3 ft. long and are made of a dry 1:4:8 mixture, with the 6-in. interior diameter. Expansion joints are provided across the dam parallel to the axis of the stream at intervals of approximately every 60 ft., and at each expansion joint there is a vertical well to which the horizontal drains are connected. These vertical wells lead to a gallery

FIG. 5. DETAILS OF DRAIN PIPES IN LOCH RAVEN DAM

which extends throughout the length of the dam and which get free discharge into the tail water on the downstream side of the dam.

Fig. 4 shows a section of the dam which is now being built to an elevation of 192 ft., and how the dam will be raised to the proposed crest elevation of 237.5 ft. The last three feet of the heights to bring the dams to these levels will be secured by means of flashboards.

Two 36-in. drain pipes are provided at elevation of

inverts of 164 ft. A.M.T., one on each side of the spillway, and these will make it possible to drain the lake should it ever be found necessary to do so. These gates will also be used while filling the relief openings which have been left in the first half of the dam to carry the water of the river during the construction of the second half.

Gate House

The gate house which will control the flow of the water into the city is built into the dam near the west bank of the stream, and will be so constructed that there will be duplicate gates which will make it possible to send water to the city through either one or both of the two gate chambers. Should any gate get out of order it will be possible by means of stop planks to shut the water out of the gate chamber, and a 24-in. drain for the gate chamber is provided, which will discharge into the tail waters of the dam. Provision is also made in this gate house to take water from varying depths.

During the summer time, when trouble may be experienced from the presence of algae growths, the water for the city will be drawn from the bottom of the lake, as experience has shown that the algae growths are much more numerous in the top layers than in the bottom layers. Should the dissolved oxygen become exhausted in the lower layers, and in times of turbid waters, when the top waters will settle clear much more rapidly than the bottom waters of the lake, the water will be drawn from the top.

The conduits connected with the two chambers of the gate house are each 8 ft. in diameter and will be brought together just below the gate house into one 10-ft. conduit, which is connected with a 10-ft. steel pipe line. This steel pipe is surrounded by concrete on the outside and lined with mortar on the inside, which lining has been placed by means of a cement gun, and is reinforced with wire mesh.

The gate house, when it is raised to the height recommended by the consulting engineers, will be provided with a hydro-electric plant which will generate electricity, the turbine being operated by the water passing to the city and by using the waste waters in excess of the water being consumed by the city. This current will probably be carried into the city limits and be used at the filtration plant.

The house which will be built over the gate chamber at the present time will be merely a temporary one of wood. A more permanent structure of stone or concrete would have to be soon torn down, as it is possible that the dam will have to be extended to the height recommended by Messrs. Freeman & Stearns in the course of the next ten years.

Bonding High Dam to Present Structure

When it is decided to carry the present structure up to the height originally recommended, it is proposed to place several rows of porous drains along the steps of the present dam, so that any water getting into the joint between the old and the new work will be intercepted before it can produce internal stresses, which would threaten the safety of the dam.

In order to bond the new structure to the old, large plum stones are placed projecting above the finished surface of the present structure, and these stones will be of great assistance to keep the new structure from sliding on the old. (Fig. 7.)

Fig. 6. Foundation Pit, Showing Seamy Rock Formation

Fig. 7. Plum Stones Imbedded in Present Dam Crest for Future Bonding

If it is decided that these plum stones will not furnish sufficient strength to prevent the sliding of the dam, holes can be drilled at regular intervals along the crest of the present structure, and iron bars can be grouted into these holes and extended into the new structure. It is believed that the system of drains combined with the plum stones and the iron bars will provide sufficient strength against sliding and provide for a sufficient bond between the new work and the old.

Materials of Construction

The stone of which the dam is constructed is taken by the contractors from a quarry located on the property of the city on the west bank of the stream, just below the old dam and about one-half mile below the bend where the new dam is being constructed. The larger stones taken from this quarry are used as plum

stone, while the smaller pieces are crushed by the contractor in order to furnish stone for the concrete. The stone from the quarry is a low grade of limestone, and it is also crushed and rolled in order to secure sand for the concrete. On account of its hardness, the contractor has experienced considerable difficulty in getting enough sand by this method to carry on his work, and he has been forced to buy sand from Baltimore city, from a company which secures the sand by dredging Baltimore harbor and the surrounding waters.

As already noted, the cutoff wall which extends below the foundation line and to the top of the upstream face of the dam is built of 1:2:4 concrete. The main body of the dam is built of 1:2½ concrete, in which are placed plum stones which amount to from 20% to 33⅓% of the total volume of the masonry in the dam, depending upon the part of the structure in which the plum stones are placed.

Every carload of cement that is used in the dam is sampled and tested before the contractors are allowed to use it.

CONSTRUCTION

The new dam is being built in the old Loch Raven Reservoir and the first half of the masonry was constructed inside of a coffer-dam, built to within about 50 ft. of the eastern shore of the old lake (Fig. 1.) This coffer-dam was built of two rows of interlocking steel sheet piling placed about 15 ft. apart. There was about 15 ft. of mud and earth in the bottom of the old lake overlying the rock, and the sheet piling was driven through this mud and earth to solid rock. Upon the completion of the coffer-dam and in carrying out the earth excavation in the bottom of the lake, it was found very difficult to hold the earth on the inside face of the sheet piling so as to furnish proper support for the steel piling and the contractor was forced to place large stones on the inside of the coffer-dam against the inner row of sheet piling, which stone was afterwards used for the plum stone in the dam wherever it could be recovered.

This coffer-dam for the first half of the construction was very tight and the water was kept down in it by the use of a single 4-in. pump which did not need to operate constantly.

The rock encountered in the excavation is a mica schist, varying in hardness according to the amount of mica which was present. The rock was of a very seamy character, although there was little or no percolation through it excepting in the top seams, and the cutoff wall, which it had been proposed to carry down 30 ft., was stopped at a depth of about 15 ft. below the general excavation of the rock. Owing to the seamy character of this rock, which is shown in one of the accompanying views (Fig. 6), and the sharp tilt of the strata, there was no attempt made to secure a level bottom for the foundation, and the underdrains were placed over the seams between the strata at intervals of about 20 ft., instead of at right angles to the main underdrain on the downstream face of the cutoff wall.

The dam itself was built in blocks, forms being used to secure these blocks. The joints between these blocks were so arranged that there is no continuous horizontal joint throughout the dam.

Both the excavation and the placing of the concrete and the plum stones were handled from a number of derricks, which can be seen on Figs. 2 and 8.

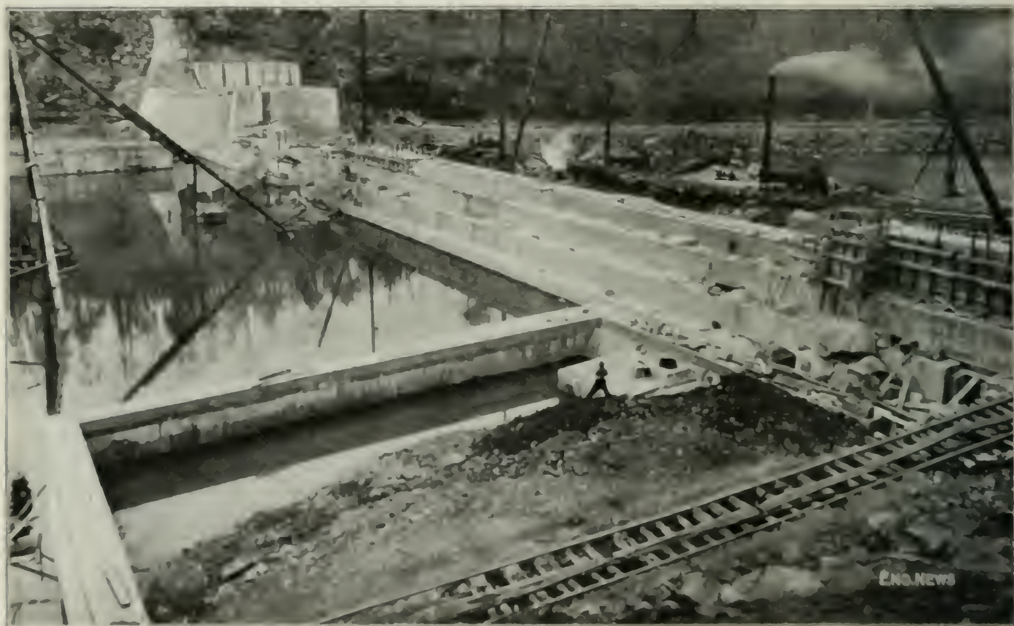

FIG. 8. VIEW OF LOCH RAVEN DAM, TAKEN MAY 1, 1914, SHOWING PRACTICALLY COMPLETED PRESENT STRUCTURE

When the first half of the masonry structure was completed, the contractors, largely through overconfidence bred by the ease with which the water was handled in the first half of the dam, built the portion of the coffer-dam parallel to the axis of the stream and upon the completed structure of wooden plank instead of the steel sheet piling.

When the coffer-dam for the second half of the dam was completed it was found that this portion of the coffer-dam leaked very freely and the work of proceeding with the structure of the second half of the dam was delayed for several months before the coffer-dam could be made sufficiently tight to work inside of it.

PERSONNEL

The original plans for this dam, before being revised by the writer, were drawn by former Water Engineer Alfred M. Quick, and the design and construction have been directly under the supervision of Emory Sudler, then Division Engineer of the Gunpowder Supply improvements. The Assistant Division Engineer, P. A. Beatty, assisted in the design of the dam and has been in immediate charge of its construction and the construction of the roads, conduits and bridges, which are incidental to the construction of the dam. The Resident Engineer at the dam was Talbott Todd, who resigned his position with the city to take charge of the construction of the dam for the contractors in August, 1913. Mr. Todd was succeeded by Everett Patterson, who is now the Resident Engineer in charge of this work.

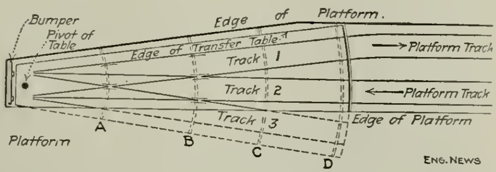
A Swinging Transfer Table for Shifting Locomotives

In the new Snow Hill station of the Great Western Ry. at Birmingham, England, there is a pair of stub tracks for local service and it was desirable to provide means for promptly switching out the engine of an inbound train. This is effected by the use of a segmental or fan-shaped transfer table, pivoted at the extreme end of the tracks. This is shown in the accompanying cut.

The table has three tracks radiating from the pivoted end. Two of these tracks are normally in line with the converging ends of the inbound and outbound tracks. When a train stops on the inbound track, the engine is uncoupled and runs onto the transfer table. This is then swung to bring its engine track in line with the outbound track, and at the same time its third track is lined up with the inbound track. In this way the pit is kept closed all the time and there is no liability of derailing cars in case of accidental movement while the engine is being moved. As soon as the engine is run off, the table is returned to its normal position. It will be understood that the station has high platforms, level with the floors of the cars, so that the transfer-table pit and the dead side of the table extend under the platforms.

The table is about 70 ft. long, with widths of 13 ft. and 39 ft. at the inner and outer ends. This width is between the centers of the two side or radial girders, and these girders are connected by four curved transverse girders, between which are framed parallel longitudinal girders, all covered by a steel deck. Under each cross-girder is a curved rail on the floor of the pit, for wheels carried by the girder framing. The pivot and bumping block are carried by a substantial masonry pier.

Upon the framing (beneath the deck) is mounted a motor-driven drum, upon which is wound a cable having its ends anchored to the sides of the pit. The travel (at the circular end of the table) is about 8 ft. 6 in. The



PLAN OF SWINGING TRANSFER TABLE FOR SHIFTING THE LOCOMOTIVE OF AN INBOUND TRAIN TO AN OUTBOUND TRACK AT THE SNOW HILL STATION OF THE GREAT WESTERN RAILWAY, BIRMINGHAM, ENGLAND

(A, B, C, D are transverse girders of the table, with wheels riding on curved tracks in the floor.)

operation is controlled by a lever on the platform and this is interlocked with the signal equipment, so that the table cannot be operated without the knowledge of the signalman who handles the train movements at the station.

The Magnitude of the Aluminum Industry is shown in the following table, which gives the production since the beginning of the industry in 1883 and the domestic consumption of the metal since 1904:

1883	83	1900	7,150,000
1884	150	1901	7,150,000
1885	283	1902	7,300,000
1886	3,000	1903	7,500,000
1887	18,000	1904	8,600,000*
1888	19,000	1905	11,347,000*
1889	47,468	1906	14,910,000*
1890	61,281	1907	17,211,000*
1891	150,000	1908	11,152,000*
1892	259,885	1909	34,210,000*
1893	333 629	1910	47,734,000*
1894	550,000	1911	46,125,000*
1895	920,000	1912	65,607 000*
1896	1,300,000	1913	72,379,000*
1897	4 000,000		
1898	5,200,000	Total	377,737,779
1899	6,500,000		

*Consumption. The figures for 1913 do not include the weights of imported leaf aluminum, valued at $1228; table, kitchen and hospital utensils, valued at $40,947, and "All other manufactures" of aluminum, valued at $353,844. The secondary aluminum produced in 1913 was 2198 short tons; the quantity of recovered aluminum contained in alloys was 2456 short tons.

The use of the metal is now being extended on a much larger scale, as in the construction of welded tanks, cooking vats and vessels which are employed by brewers, preserve manufacturers, fat recoverers and in similar industries where a metal that will conduct heat, will not corrode and is not poisonous is essential.

Other uses for aluminum vessels on a large scale are in the manufacture of essences and syrups, varnishes, fatty acids, edible oils and nitric acid. A large number of firms abroad are using aluminum in the varnish-making industry. Welded aluminum tanks are now being employed for obtaining and measuring acid and for piping and conveying the acid in the works. A number of aluminum tank cars have been made for the conveyance of strong nitric acid in bulk and the results have been satisfactory. The use of aluminum wire as a conductor in long-distance power-transmission schemes is not new. A recently developed branch of the aluminum industry is the manufacture of powdered metal which is used extensively as a paint pigment, in explosives, in lithographing and in printing. Aluminum foil, though not exactly a new product, is now being used on a larger scale than ever before, owing to improved methods in its manufacture after long and expensive experiments which have reduced its cost appreciably. Aluminum foil has partly displaced tinfoil for wrapping articles such as cheese, chocolate candles and tobacco.

Design and Construction of Outfall Sewer, Carlisle, Penn.

By [illegible] Bryan*

The main outfall sewer conveying the sewage from the borough of Carlisle, Penn., to the disposal plant is about 1.7 miles in length (see plan and profile, Fig. 1). It is constructed of 18- and 24-in. double-strength terra-cotta pipe. It follows in the general course of the Letort Spring, a shallow stream which flows through the eastern portion of the borough.

Design of the Outfall Sewer

The sewer was designed to carry the sewage from a population of 27,000, and was designed on the assumption: (1) that the average amount of sewage contributed to the system per capita per day would be 100 gal., and (2) that there would be an infiltration of ground water into the main amounting to 5000 gal. per mile of sewer per day.

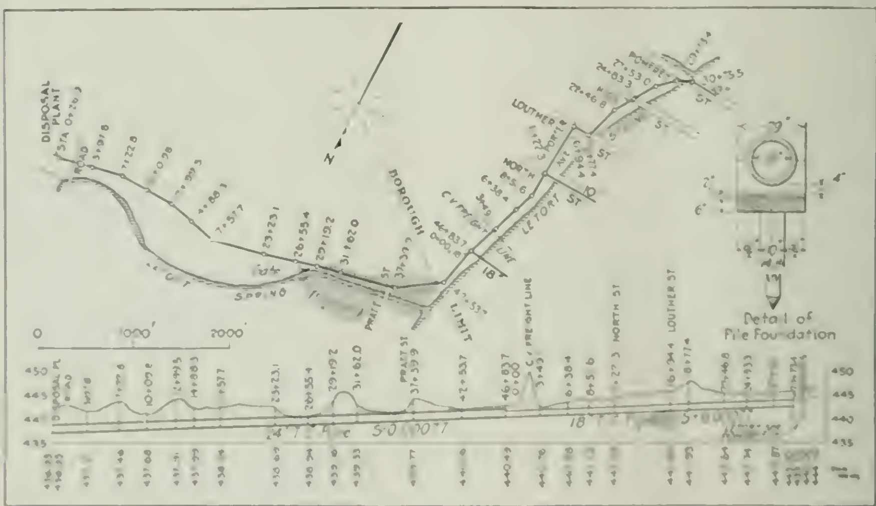


Fig. 1. Plan and Profile of Outfall Sewer, Carlisle, Penn.

The sewage from the town is discharged into the main outfall at three points, the sizes of the branch sewers being 10, 12 and 15 in., respectively (see article on this sewerage system in general, by the present writer, in Eng. News of July 2, 1914). The total fall available between the point where the main sewer draining the southeastern portion of the borough joins the outfall at the corner of North and East streets, and the site selected for the plant, is 9 ft. The velocity of flow through this sewer was fixed at 1¾ ft. per sec. and the gradient determined in accordance therewith. At every 90° point on the line a drop of 1 in. was made in the manhole at that point, and at the other turns the amount of fall allowed in the manhole varied from ¼ to ½ in., depending upon the sharpness of the turn.

A careful study was made of the topography of the section through which the sewer passed, and the sewer was so located as to permit its construction in the shallowest cut possible and at the same time provide a covering of at least 2 ft. over the pipe. This was considered essential because the line, once outside the borough limits, was laid out through cultivated fields.

Construction of the Sewer

Bids for the construction of the outfall were received in March, 1913, and the contract was awarded to the lowest bidder, J. L. Dick, of Scottdale, Penn., at $13,098.

Excavation—Construction work was not started very promptly as the contractor had other work which he wished to finish, and again, in the judgment of the engineer, the work was not of sufficient magnitude to raise any doubt as to the contractor's ability to finish it within the specified time limit of 180 days. Work was started in June, however, and, as a comparatively small force was employed, it was not finished until February, 1914. The principal cause of this delay was the fact that the contractor expected to have only a small quantity of rock excavation, but once construction work was started a large amount of rock was encountered. The contractor, not being well equipped to handle this rock, kept opening up more and more trench in the hope of finding some dirt excavation, with the result that he finally had 3000 lin. ft. of trench opened and no pipe laid. At this point the engineer was obliged to [illegible] this procedure and no further trench was laid out until the pipe had been laid in the trench already opened up. Progress on this portion of the work was necessarily slow because the contractor did not have the machinery to handle the work economically nor did he seriously consider the purchase of suitable apparatus until the work was nearly completed. Figs. 2, 3 and 4 give an idea of the amount of rock encountered at points where little or no rock was anticipated.

During construction, no serious difficulty was experienced. The majority of the excavation was in dry material, only about a half-mile of the pipe being laid in wet trench. Probably the worst stretch encountered lay

*[illegible]

between High and Pomfret streets (Fig. 1) where the line passed through a truck patch. Here the material excavated was a sort of marl, saturated with water. It provided no foundation for the pipe and a pile-and-plank foundation was built to support it (Fig. 1). This entire section had to be closely sheeted, and it was found necessary to drive the sheet piling fully 2 ft. below the invert of the pipe to prevent the material from breaking through underneath the sheeting. The crossing under the freight track of the Cumberland Valley R.R. was made in tunnel and was carried through without trouble, although the tunnel was about 150 ft. long and was driven through filled ground.

Rock Drilling—The rock on the outfall sewer was drilled by means of Rand jack-hammers or butterfly drills, operated by steam (Figs. 5 and 6). Two of these hammers were operated by an 8-hp. vertical boiler, which supplied steam to them through 1-in. pipe. It was found that the steam could be carried a distance of about 150 ft. from the boiler before condensation became too great to permit the operation of the hammers. This necessitated the moving of the boiler every 300 ft. When but

Construction Views on the Outfall Sewer at Carlisle, Penn.

(Figs. 2, 3 and 4 show the unexpected amount of rock encountered. Figs. 5 and 6 show steam jackhammers or butterfly drills at work.)

one drill was in use it was found that steam could be carried from 200 to 250 ft. before becoming too cold.

From the results obtained by this contractor in drilling the rock in the manner described the following conclusions have been drawn: (1) Butterfly drills operated by steam will not put down holes in solid rock over 5 or 5.5 ft. in depth. (2) Where a seam of soft or shattered rock is encountered the steam drill will clog and refuses to go through, often necessitating shooting shallow holes and redrilling after cleaning out the soft seam. (3) The heat under which the operator was obliged to work was excessive, and this heat and the exhaust steam necessarily tended to reduce the efficiency of the operator. In deep cuttings and also under certain atmospheric conditions, steady work was impossible. (4) The cost of the maintenance and operation of the plant was excessive. The writer is convinced that the cost of drilling the rock on this work could have been more economically handled by the use of a portable air compressor.

SEWER JOINTS—As stated, the entire 24-in. portion of the line was constructed during the summer months and at a time when there was little or no water in the trench to contend with. Joints were made in the usual manner, using a rich cement mortar which was prevented from passing through to the inside of the pipe by first wrapping a strand of jute around the spigot end of each pipe as it was inserted into the bell end of the pipe previously laid. To further aid in keeping the mortar in place, a piece of muslin 9 in. wide was wrapped completely around the joint and held in position by tying at the top of the pipe. An inspector was present on the work practically all of the time, and was especially careful to see that the bottoms of the joints were well made and the pipe well laid.

During the winter months, the meadow marked A on Fig. 1 is flooded by the authorities of the Carlisle Indian School for the purposes of a skating pond, and under present conditions about 1200 lin.ft. of the outfall sewer along this meadow is subjected to a head of about 6.5 ft. of water, amounting to a pressure of about 1.5 lb. Under these conditions the infiltration of ground water into the sewer is excessive. Measurements taken at the manhole nearest the point A have shown a stream 10 in. deep flowing through the sewer.

A careful examination of the barrel of the pipe has failed to reveal any excessive leakage at any one joint, but water seemed to enter the pipe through numerous pores in each joint. Various attempts to repair this leakage have proved in general unsuccessful. The writer is satisfied that the joints were carefully made and the pipe well laid, and this at a time when the ditch was dry.

Leakage at this point is unquestionably increased by the fact that throughout this distance the pipe is laid in a shallow cut, and through rock. For this reason the back-filling is much more porous than it would have been had the pipe been laid in dirt excavation.

The fact that so much leakage has developed under the conditions cited has raised in the mind of the writer the question whether after all cement joints are the most satisfactory joints for vitrified sewer construction.

COST OF CONSTRUCTION

The unit prices upon which the contractor's bid was based were as follows:

Material	Diam. in.	Depth ft.	Price
Terra cotta pipe	24	0 to 4	$1.30 per lin.ft.
Terra cotta pipe	24	4 to 6	1.52 per lin.ft.
Terra cotta pipe	24	6 to 8	1.82 per lin.ft.
Terra cotta pipe	24	8 to 10	2.22 per lin.ft.
Terra cotta pipe	24	10 to 12	2.72 per lin.ft.
Terra cotta pipe	18	4 to 6	1.33 per lin.ft.
Terra cotta pipe	18	6 to 8	1.48 per lin.ft.
Terra cotta pipe	18	8 to 10	1.53 per lin.ft.
Terra cotta pipe	18	10 to 12	1.58 per lin.ft.
Terra cotta pipe	18	12 to 16	1.82 per lin.ft.
Terra cotta pipe	18	16 to 18	2.25 per lin.ft.
Rock excavation			2.85 per cu.yd.
Brick manholes			4.00 per vertical ft.
Cast-iron frames and covers			18.00 apiece complete
Concrete masonry			6.50 per cu.yd. in place

The price paid by the contractor for labor was $2 per day of 10 hr.

The final estimate for this work amounted to $21,735, or a cost to the borough of $2.91 per lin.ft. of completed sewer, including engineering and inspection. Records kept during the construction show, up to the point where the line crossed High St. (Fig. 1), a profit of about $800 to the contractor. It is probable that this profit was lost in the construction of the remaining distance to Pomfret St. on account of the difficulties to which reference has previously been made.

The cost of the outfall sewer will be met by a general assessment on the assessed valuation of the entire borough.

This sewer was designed by and constructed under the supervision of T. Chalkley Hatton, now Chief Engineer of the Sewerage Commission of Milwaukee, Wis. The writer was the resident engineer in charge of construction and Leo D. Skemp was the superintendent of construction.

A Controversy Over the Question of Force Account versus Contract Work at New Orleans

We have recorded in recent issues of ENGINEERING NEWS the extent to which some cities are carrying on work at the present time by the direct employment of labor, or by force account as it is commonly called, instead of by letting contracts. In our issue of July 16 we described the manner in which the city of Minneapolis is carrying out over three and one-half million dollars' worth of construction work without letting contracts. It is the general rule, however, that this plan of carrying on work meets with serious opposition. In many states stringent statutes are in force requiring that all public work shall be done by contract and shall be advertised and let to the lowest bidder. There are many engineers who believe that while in exceptional cases work can be carried on efficiently by day labor, the general liability to political interference, etc., is such that on the whole the contract system is to be preferred.

The city of New Orleans is just now the seat of a lively controversy respecting the manner in which the extensions of its waterworks and sewerage system should be made. As many of our readers will recall, the building of a sewerage system for New Orleans was not undertaken until 1903. In the four years from 1903 to 1907 a large amount of work was done. The main trunk and outfall sewers were constructed and a large part of the business and residence portions of the city were provided with sewers. All this work was done by contract.

In September, 1907, bids were received on four addi-

tional contracts for sewer extensions. These bids were found to be about one-third greater than the engineers' estimate of the cost; and this fact, together with the limited appropriation available, caused the bids to be rejected. The Sewerage and Water Board then determined to undertake the construction of these sewers by force account after receiving a legal opinion that they had authority to carry on the work in this way.

In the six years since that time all work on sewer extension work has been done by force account, no contracts being let. The Board has built in this time 193 miles of sewers, from 8 in. to 27 in. in diameter, at a total cost of $1,312,000. The work done by contract previous to that time had cost about $5,000,000. In 1910 the Board further adopted the policy of building by force account all extensions to the city's water distribution system. Heavy construction work on the city's storm-water drainage system, however, is still done by contract.

As was to be expected, the conduct of work by force account excited criticism and antagonism. Claims were made that the Board had no legal right to carry on its work in this manner. The controversy appears to have become a political issue and was carried into the State Constitutional Convention held last fall. This convention inserted a clause in the constitution empowering the Board to continue to do its work either by force account or contract until Sept. 1, 1914, providing that any single piece of work exceeding in cost $25,000 should be let to contract and further providing that the State legislature, at its session in the spring of 1914, might determine whether the permission to the Board to work by force account might be extended beyond Sept. 1.

In view of the large amount of criticism and discussion concerning the work done under the direction of the Board, a special investigation committee was appointed in December last, consisting of Messrs. J. F. Coleman and Arsene Perrilliat, and Prof. W. B. Gregory. This committee was requested to report as to the comparative cost of the work done by force account and by contract, and also as to the organization and efficiency of the Board's staff with the adequacy or inadequacy of the salaries paid.

This committee presented its report, May 6, 1914, and stated that the design and execution of the drainage, storage and water systems of New Orleans are exceptionally good and reflect great credit upon those who are responsible therefor. The committee then proceeded to a discussion of the relative merits of contract work and force account, and concluded that under the same terms and conditions the work could be done by contract at a lower cost and yet with a reasonable profit to the contractor. The committee therefore recommended that the work of extending water, drainage and sewer conduits should hereafter be done wholly by contract, but that the making of sewer and water house connections and the maintenance of the system should be done by the Board's own forces. The committee also made an elaborate report upon the organization of the Board's engineering and other departments and submitted certain recommendations for its reorganization.

At the same meeting of the Sewerage and Water Board, at which the report of the investigating committee was presented, George G. Earl, General Superintendent for the Board, submitted a report emphatically contradicting the investigating committee's statement as to the advantages of contract work and showing that in every respect the city had been the gainer by the adoption of the force account plan. Mr. Earl stated that on the contracts for which the bids were rejected in the fall of 1907 their execution by force account showed a saving of at least $562,000 to the city as compared with the prices bid by the contractors. Engineers desiring a forceful discussion, pro and con, of the subject of force account vs. contract work would do well to apply to the Sewerage and Water Board of New Orleans for copies of the reports.

Following these two reports, the Board instructed its counsel to submit to the legislature a bill which would permit it to continue the policy of doing work by force account within the limit fixed by the constitution. It further submitted the whole matter to a board made up of Messrs. Rudolph Hering, George W. Fuller and Harrison P. Eddy. The report of this board, dated June 20, 1914, has just been printed. This board fully sustains the Water and Sewerage Board of New Orleans in its policy of carrying on work by force account. One of the strongest paragraphs of its report we quote as follows:

> If the legislature should decide to discontinue the right of the board to do force account work, it will place the city in the embarrassing position of being obliged to accept the prices bid, whether high or low, or not do the work. Should the bids appear to be too high, the board, of course, can reject them and call for new bids with a delay of from three to four months; but if the board cannot do the work with its own forces these bids may be practically as high as at first. In other words, the board will be entirely at the mercy of the contractors at times when contractors are busy and bidding high prices as well as when there is a scarcity of work, and even in case of a combination of bidders to artificially inflate prices.

In addition to the report, Messrs. Fuller and Eddy gave testimony before committees of the Louisiana legislature on June 22. The legislature before adjourning enacted the bills desired by the Sewerage and Water Board, giving it permission to continue to carry on work by force account. These bills were transmitted to the Governor who submitted them to a so called "pocket veto." Had he returned them to the legislature with a veto message, it is said that they would have been passed over the veto as the vote in their favor was nearly unanimous. By merely retaining the bills, however, in his possession until after the legislature had adjourned the bills failed to become law.

Good Roads for Little Money are being constructed in Louisiana, where rock and other expensive road-making materials are rare. The work is done under the State Highway Department, which is a subsidiary department of the Board of State Engineers. The Highway Department, in all its work and discussions before the Farmers' Institutes and other meetings, has tried to make it clear that road improvement does not necessarily mean the construction of the highest type of roads, except under certain traffic conditions, but attention should be given to those methods by which the best results can be obtained with the money that is, or will be, available for the various highway projects. The accompanying table gives a summary of road work during the past six years.

Parish	General Character	Mileage	Cost	Average cost per mile

Road-Oil Specifications and Tests*

By Clarence B. Osborne†

In the preparation of specifications for asphaltic oil for road building the engineer has three problems presented: (1) He must have requirements controlling the chemical purity of the oil, i.e., he desires an oil that is free from foreign material and products of decomposition produced during refining; (2) He must control the chemical composition of the oil; (3) he must control the physical properties of an oil so that it will actually perform its proper function in the road construction.

Specifications for chemical purity of road oil are as follows:

(1) It shall not contain more than one-half of one per cent. of sediment by volume.

The presence of even ten times this amount of sediment is not detrimental, as the oil in use on the road eventually carries as high as 90% of mineral aggregate. This specification is used to prevent the buying of sediment at the price of road oil.

(2) It shall not contain more than one per cent. of water by volume.

The presence of water in a road oil makes the oil difficult to handle when heated above 212° F., because the steam formed makes the oil boil or froth. Also, as in the case of sediment, unless the proper deduction is made water will be paid for at the price of road oil.

(3) It must, when freed from water, be soluble to at least ninety-nine and five tenths per cent (99.5%) in pure carbon disulphide.

This will give the per cent. of bitumen in the road oil.

(4) The bitumen soluble in carbon disulphide must be soluble in carbon tetrachloride to the extent of at least ninety-nine per cent (99%).

The failure to pass this specification is supposed to be an indication of an over-heated or "cracked" oil. Carbon tetrachloride is not a stable solvent in bright light and the solubility test is influenced if the test is performed in bright light.

Another specification sometimes used to determine a "cracked" oil is as follows:

(5) In CCl_4 bromide solution. The bitumen soluble in carbon disulphide must be soluble to the extent of at least ninety-nine and eighty-five one hundredths per cent (99.85%) in a solution of one hundred and thirty-five (135) milligrams of bromine to one hundred (100) cubic centimeters of the carbon tetrachloride when twenty-five (25) cubic centimeters of the solution are poured on two (2) grams of the oil in an Erlenmeyer flask, which is then placed in the dark for three (3) minutes, the solution being [illegible] filtered through a Gooch crucible using a suction equal to a column of mercury more than eight (8) inches high.

When the solution has all passed through, the crucible is washed with pure carbon tetrachloride, dried at some temperature between two hundred and twelve (212) to two hundred and twenty degrees Fahrenheit and weighed.

This test had its origin in the examination of vegetable and animal fats. The unsaturated fatty acids form insoluble bromides. The bromide carbon disulphide solvent is not stable, however. An oil having an excess of 0.15% of insoluble material would fail to pass this specification, and yet this failure might be due entirely to the unstable solvent.

The specifications to govern the different constituents that make up the bitumen of the road oil are partly included in the specifications numbered (3), (4) and (5).

The road oils are generally classified as to their asphalt content. This asphalt is not a definite chemical compound determined by chemical analysis. To determine the asphaltic content, the road oil is hardened by heating it in an asphalt oven at a high temperature. Part of the light or volatile oils, is driven off in this heating and the residue is hardened. The degree of hardness is measured by the depth of penetration of a No. 2 needle when acting under a load of 100 grams for five seconds, the residue being maintained at 77° F. If the needle penetrates 8 mm. in this test the residue, called asphalt, is said to be asphalt of 80 penetration. As can readily be seen, this residue may contain many different bitumens. The test is not a measure of a definite chemical compound.

If the assayer for copper should call all the metal extracted "copper" when the metal was of a certain hardness, then it can readily be seen that any alloy of soft and hard metals that made this certain hardness would be classified as copper. This is the practical result of the specification for a road oil when it is required to contain a certain percentage of asphaltum.

The early oil-bound macadam roads built with asphaltic oils usually required an oil containing 70 to 75% of asphalt of 80 penetration. This oil was not heavy, that is, it lacked body (i.e., low viscosity), and it was a weak binder but it was easily applied to the road surface.

The use of pressure tank wagons with sprayers for applying heated road oil has made it possible to use an oil of much higher asphalt content and of higher viscosity. The road oil that is now commonly demanded for oil-bound macadam, or for bituminous-covered concrete highways, is one that contains 90% of 80 penetration asphalt. The following specifications are suggested for such an oil:

(6) It shall contain 90 per cent. of 80 penetration asphalt.

This per cent. of asphalt is determined by heating 20 grams of the road oil in a 3-oz. salve tin in a standard asphalt oven, the temperature of the oven being maintained at 400° F. When the asphaltic residue has a penetration of 80, the oil shall not have lost in excess of 10% by weight.

The asphaltic content is the classification of the oil refineries of their different grades of road oil. The specification is of value more on this account than for any information of practical value furnished to the road builder.

(7) It shall show [illegible] not less than [illegible] degrees Fahrenheit.

This requirement prevents the use of an oil carrying very volatile constituents that would readily evaporate and might also be dangerously combustible at the time the oil was being sprayed on the road at the high temperature necessary for spraying.

The physical properties of a road oil are of the greatest importance to the road builder. The following specifications deal directly with the measurement of the important physical properties.

(8) It shall show a float test of not over 100 seconds when tested at 32° Fahrenheit temperature. This test is described in Bulletin No. 38 issued by the Office of Public Roads, United States Department of Agriculture.

*Abstracted from the "California Highway Bulletin" [illegible] 1914.

†Assistant, California Highway Commission.

This float test is the measurement of the viscosity of a road oil. The requirement will prevent the use of excessively viscous road oil, one that is difficult to apply and is slow to absorb the mineral aggregate necessary to the building up of the proper wearing surface.

(9) The oil shall show a specific viscosity of not more than one hundred (100) when tested with the Engler viscosimeter at a temperature of two hundred and twelve (212) degrees Fahrenheit.

This test will prevent the use of an oil that is too viscous to be readily applied to the road surface from the oil-spraying wagon.

(10) It shall show an adhesive test of not less than 300 seconds for three revolutions with the Osborne adhesive machines, when the oil is tested at a temperature of 77 degrees Fahrenheit, the load being 3 kilograms.

This test is the measure of the oil's power to prevent relative motion of two concentric cylinders when the oil acts as a binder between the surfaces of the two cylinders. The inner cylinder is 1.995 in. in diameter, the outer cylinder is 2 in. in diameter, the outer cylinder being in the form of a loose collar 2 in. wide. Its inner surface is coated with the oil to be tested. The outer surface of the inner cylinder is coated with oil and the collar then forced on the inner cylinder, which is maintained in a stationary position.

The outer collar is wound with cord to which a three-kilogram weight is attached; the pull of this weight causes the collar to revolve; the thin film of road oil between the two cylinder surfaces offers a resistance to this turning. The temperature of the oil being tested is maintained at 77° F. by means of water circulating in the inner cylinder. The measurement of the adhesive value of the oil is the length of time required for three complete revolutions of the collar.

Oils containing the same percentage of asphaltum will often show the greatest difference in their binding properties. Oils possessing the same viscosity will likewise often show a wide difference in adhesiveness.

As an example, one oil may be largely made up of heavy lubricating grease, another may be very free from lubricating material but they may both flow through a given-sized orifice at the same rate, when heated to the same temperature, that is, they have the same viscosity. The lubricating oil would lack binding power and be unsatisfactory for road construction; the other would be desirable. The adhesive specification would prevent the use of the unsatisfactory lubricating oil.

The asphalt contained in a road oil is required by some road builders to possess a certain ductility.

(11) The ductility of the asphalt which has been reduced to a penetration between 75 and 85 shall not be less than 110 centimeters.

This test is made with asphalt maintained at 77° F. and the pulling shall be at the rate of 5 cm. per min., using the Dow ductility machine.

There is a woeful lack of uniform specifications for road oil and uniform methods of performing the tests. In the determination of the asphaltic content of an oil, the temperature for the asphalt oven is specified sometimes at 325° F., and from that to as high as 500° F.

The dish containing the road oil during the reduction is in some laboratories as small as a thimble, and in others, large enough to hold 500 grams; sometimes cylindrical, and other times semispherical in shape. Some tests require the use of an oven, others require heating in the open air. As has been shown, the "asphaltic content of an oil" is, at best, a rather indefinite term, and when we have added to this the different methods used and the wide range of equipment used, the "asphaltic content" becomes even more of a vague description.

The asphaltic road oils are, for the most part, a by-product of the oil refineries. They are a relatively cheap material. This cheapness saves the road oils from being adulterated with other material. It is expensive to add anything to the oil. The natural oil itself rarely carries undesirable material. The tests for water and sediment will take care of foreign materials brought in by the crude oil.

Some road engineers have regarded oil containing sulphur as dangerous to use because the sulphur is supposed to make the product unstable. Many oils and asphalts carrying sulphur have given good service for long periods of time and if sulphur does tend to make the oil unstable, this action is too slow to be of importance in the life of the oil used in the road construction.

Notes on Maintenance of Wachusett Reservoir

By J. A. Cushman*

Much has been published concerning the construction of the Wachusett Dam and Reservoir of the Boston Metropolitan Water Supply, but little has been written about its maintenance. A few interesting, if not important, points have developed since this great reservoir was completed and filled, which maintenance engineers, and indirectly, construction engineers as well, may find valuable.

Survey Reference Marks

The first is in regard to the maintenance of construction benches, reference hubs or traverse points, and intermediate triangulation stations.

The bottom of the Wachusett Reservoir was striped of all soil. Preliminary to this stripping, the whole area was laid out in 500-ft. squares over which elevations were taken every 25 ft. The corners of the large squares were marked by chestnut hubs, 3 in. square on top and tapered to about a ½-in. sq. in their lengths of 3 ft. These hubs were guarded by triangular fences to prevent their being disturbed as the soil was removed. Of course, a great proportion of these hubs were within the site of the reservoir—only a comparatively few of them on the edges coming above the high-water line. In the final clearing of the basin all the hubs below the flow-line and all which were on the edge and liable to be washed in, were removed, leaving very few points for future use.

In a reservoir several miles long, the lack of a few such points is liable to cause considerable inconvenience, to say the least, at some time. The writer, therefore, suggests that, before such wholesale removal, new hubs or points be placed on the line of hubs to be removed, so far above the ultimate flowline as not to be disturbed, undermined or washed away, and that all such hubs or points be properly guarded and tied in to permanent structures. This also applies to bench marks which will be submerged or undermined by the rise of the water. All hubs and benches already above the flowline should be carefully preserved and removed from time to time as it becomes necessary.

*Assistant Engineer, Wachusett Department Metropolitan Water and Sewerage Board, Clinton, Mass.

A few new triangulation stations should be established, the old ones which are liable to be of use should be renewed, new flag poles placed and the trees and brush around them kept cut down. The cost of this work does not amount to a great sum coming under regular maintenance accounts and done a little at a time in the year's work, but may mean considerable expense and trouble if the work is left to accumulate for several years, and more still if it is left undone.

Reservoir Slope Erosion

The second point is in regard to the action of wind and waves on the steep slopes and their consequent erosion. In the original stripping of the Wachusett Reservoir, rules were made for the guidance of engineers and inspectors. These rules were designed to allow for the action of waves in the full reservoir. For steep slopes the rules were as follows:

Where the margin is along a steep sandy slope it is expected that the shore will gradually take a 3 to 1 slope between [illegible] and [illegible] or between high and low water. Below [illegible] the final slope may be assumed as ½ to 1 and above [illegible] as 1 to 1. Sections of the natural slope should be taken by survey or otherwise plotted to convenient scale, and the assumed slopes, as above, drawn on these sections so as to give approximately equal areas above and below the intersection of the 3 to 1 slope with the natural slope. (See sketch A, Fig. 1.) Strip to intersection of 1 to 1 slope with natural surface.

In case of very steep slopes extending to a considerable elevation above high water and where it is probable that erosion will cause landslides extending to the top of the slope it will be necessary to strip the entire slope. (Sketch C, Fig. 1.) Where it is necessary to strip to the top of the steep slopes the clearings should be carried back about 15 ft. beyond the top of such slope.

On the accompanying sections of two steep slopes, are shown this original stripping point as located according to the above rules, and also the flowline and top of bank as actually existing in 1911, three years after the reservoir was first filled. The first section (Fig. 2) is of a bank on the north shore of the basin exposed only to south and east winds, while Fig. 3 is on the south shore and is exposed to northeast, north, northwest and west winds. In each of these cases, the bank had been eroded by wave action at its base, and had slid, necessitating much additional stripping. The second of these banks is still changing and it is anticipated that it will continue to do so for some time to come. The action of the wind as well as of the waves is very noticeable on this bank—a layer of sand several inches in depth having accumulated on the top of the bank and in the woods behind it. The ma-

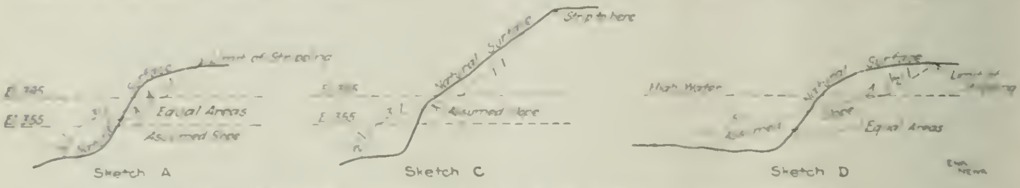

FIG. 1. SKETCHES ILLUSTRATING THE DESIGN OF STEEP RESERVOIR BANKS

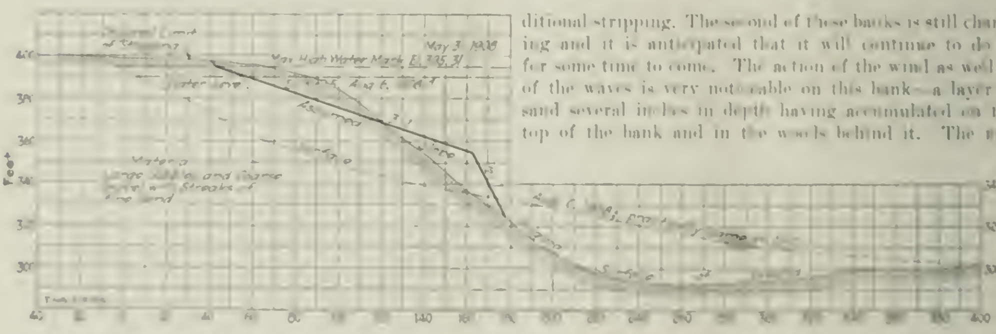

FIG. 2. SLOPE OF NORTH SHORE OF WACHUSETT RESERVOIR AS ORIGINALLY STRIPPED AND AFTER HAVING BEEN FILLED THREE YEARS

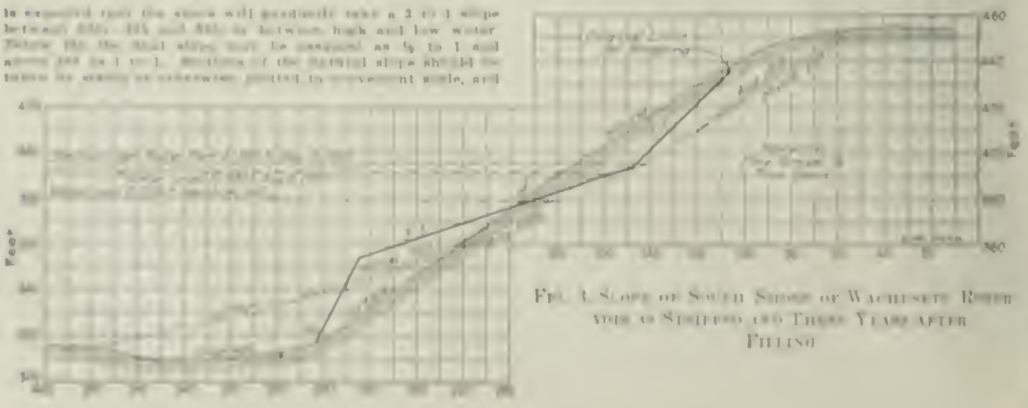

FIG. 3. SLOPE OF SOUTH SHORE OF WACHUSETT RESERVOIR AS STRIPPED AND THREE YEARS AFTER FILLING

(4) North bank in original condition; that is, before stripping or grading. (5) North bank, from another viewpoint, after having been subjected to high water; the water surface here shown is 45 ft. below high-water level. (6) Bank on south shore after high water. These views may well be compared with the profiles, Figs. 1 to 3, which show some of the original slopes, the stripped or graded slopes and the subsequent slopes after the reservoir had been filled and drawn down.

FIGS. 4 TO 6. VIEWS OF BANKS OF WACHUSETT RESERVOIR, SHOWING EFFECT OF WATER ON BANK SLOPES

terial in this bank is much finer and more compact than that in the first case.

This is a condition where the appearance of the original slopes was not such as to indicate that such great erosion would take place. The view, Fig. 4, shows the north bank before stripping (on the extreme right) and Fig. 5, the same bank after the high water of 1905, which was still 15 ft. below the flowline. Fig. 6 shows the bank on the south shore in 1904. Notice that the bank material in Fig. 6 is much finer than that shown in Fig. 5.

As a result of this experience it would seem that the ultimate slope attained by a coarse gravelly material containing many cobbles, acted upon by waves, will be between 2 to 1 and 5 to 1, the last probably being the permanent slope. As a modification of the diagram shown in Sketch *A* (Fig. 1), the writer would suggest that shown in Sketch *D*, substituting slopes of 5 to1, and 1½ to 1, for the slopes of 3 to 1 and 1 to 1 as shown in Sketch *A*, and omitting entirely the steeper slope of ½ to 1. Actual sections show that if there is a change of slope below low water it is even flatter than 5 to 1.

Shallow Flowage

Experience has shown that an area which is flooded only for a few months in a year and then for a depth of less than 5 ft., will grow up to goldenrod, sweet fern, blackberry vines, and small poplars, birches and alders, in a very short time, causing an unsightly and marshy appearance to the locality, which is undesirable in a public water-supply. Such conditions should be noted during construction and the work done at that time, as it is much more expensive for a small maintenance gang to do this work, than it would have been for the contractor's gang to do it, while at work on this part of the project, with its larger outfit of tools and men.

Reforestation of Drainage Areas

The last point is in connection with the work of reforestation. In 1909, E. R. B. Allardice, Superintendent of the Wachusett Department of the Metropolitan Water Board, in an article published in Engineering News, on "Reforestation of the Marginal Lands of the Wachusett Reservoir," stated: "Thus far, no serious fires have occurred, though several have started which would have caused great damage but for the effectual protection given."

In 1911, the reservation was visited by several serious fires. One, caused by sparks from a locomotive started on adjoining land, and spread by a moderate wind, swept a width of 2000 ft., over three, three-rod roads and over three 15-ft. interior forest roads, and was only stopped at a 30-ft. state highway by the combined efforts of about 25 men with hand extinguishers and shovels. If there had been no one there it would have jumped that obstacle as it had the earlier ones. This fire completely destroyed white pines 10 to 15 years old, averaging 12 to 15 ft. in height. Another fire, caused, presumably, by a cigar or cigarette butt carelessly thrown from a passing electric car, crossed two 15-ft. forest roads but was stopped at a 30-ft. highway. Both fires were on land formerly used for pasturage or cultivation and the pines were the tallest growth.

These two fires demonstrated the usefulness of a fire guard less than 30 ft. in width, at least. It is extremely doubtful if the second fire could have been stopped at the 30-ft. highway if the growth had been higher, as the fire-fighters could not have stood the heat. All the fires which have occurred and been overcome on this reservation have shown the wisdom of having fire guards (40 ft. is none too wide), and of keeping them mowed and cleared, if they are to be at all efficient as such.

It is not the desire or purpose of the writer to decry the use of 15-ft. interior roads. The more interior roads there are the more chances there are of limiting the fire to a small area, especially if it is discovered early in its career. They are also indispensable in getting into the reservation for the purpose of spraying for brown-tail and other caterpillars, hauling out wood from improvement clearings, and many other purposes. But it is his desire to emphasize the need of enough wider fire lines, kept mowed, to provide adequate and safe spaces in which to operate efficiently against a serious fire.

The Kansas City Street-Railway Franchise

The difficulties into which the Kansas City Street Ry. system had fallen and the attempt of the receivers and courts to secure a satisfactory reorganization based on an appraisal and a franchise scheme outlined by B. J. Arnold were noted in Engineering News of May 22, 1913, together with a summary of Mr. Arnold's work in the case. After long negotiations, a compromise franchise between the city and the railway company was evolved more or less along the lines of the Arnold suggestions, and this was approved at a municipal election on July 7, in spite of considerable opposition.

The New Franchise

LIFE TERM—The term is 30 years with provisions for forfeiture and purchase by the city before expiration under conditions which protect the capitalization. At termination the company has rights securing the allowed capitalization of that date. The city may thereafter make new arrangements with the old company, cause the purchase of the system by other interests, operate the system itself or require the present company to continue temporarily.

CAPITAL—The compromise figure of $25,619,000 is taken as the total value of property in Missouri to be represented by capital (plus extensions and betterments since May 1913). Of the total $6,300,000 represents intangible items. The last named amount is to be amortized from surplus earnings divisible between city and company, with the intention that capitalization and tangible value may eventually be alike. (This amount is to be indirectly amortized by building extensions out of the city's share of surplus profit as noted below.)

The company is to provide each year such fresh capital as will, with its share of surplus profits, amount to from $[illegible] at first to $925,000 at the end. Such sums will correspondingly increase the capitalization figures. However, if net earnings exceed or fall below 30% of gross receipts for any year the annual amounts to be provided above are to be correspondingly increased or diminished.

CONTROL—The city is to participate in control and management through representation on the board of directors and on a board of control. The latter will comprise one man appointed by the company, one man appointed by the city, and a third member in the event of differences of opinion. Salaries will be paid by the company. This board will have control of routes, schedules, character of equipment and construction, system of accounts, charges to capital, classification of expenditures, auditing, etc. The company and city may each remove its representative or may apply to the courts for removal, for cause, of the other party's representative.

There will be five directors acting for the city and six for the company. The former are to be appointed hereafter by the local Court of Appeals from lists furnished by the mayor. (Initial incumbents were selected at the recent franchise election.)

Under the board of control will be the general manager

For the board of control, P. J. Kealy has been selected by the company and Robert P. Wood (a consulting engineer) by the city and have been installed by the receivers. The name of the company has been changed to Kansas City Railways Co.

REHABILITATION—Up to $1,500,000 is to be spent at once on one viaduct line. For three years, five miles of single track per year are to be built in specified locations and 25 new cars per year added. The city will pay the cost of new tracks in Union Station plaza and retain title thereto. An additional $250,000 per year is to be spent for immediate extensions to be fixed by the board of control.

EXTENSIONS—After three years, the city, by ordinance, may require any extensions not proved manifestly unnecessary—up to four track miles per year. Any extensions must be made which the board of control finds will earn operating expenses and 6%.

DIVISION OF INCOME—A guaranteed cumulative earning of 6% on the agreed capitalization is provided. From the net income the following items are to be subtracted in order: (1) expenses of management, operation, maintenance and taxes, (2) 6% return, and (3) liabilities for injuries and damages. Any surplus then remaining is to be credited to the city but used by the company for additions and extensions, until $6,300,000 shall have been expended. After this point the surplus is to be credited two-thirds to the city and one-third to the company. Until ordained otherwise, the city part of divisible surplus profits is still to be used for additions or extensions or for reduction of capital, and to that extent the city acquires a right in the property. Use of city's share in extensions may not increase capital figures. When the city's right reaches one-half the total capitalization the city becomes the owner of the system but the company possesses then a lien on the property to secure its remaining share of the capitalization.

Under operating expenses, etc., noted above, an allowance is made for maintenance, repairs, renewals and depreciation at least 16% of the gross earnings of the previous year. For damage claims not less than 4% is to be allowed. With expenditures less than these allowances, the balance is to be credited against excesses of the following years.

FARE—A five-cent rate of fare for adults will be continued with universal transfers. There will be a half fare for children of 8 to 12 years. No passes are to be issued but employees, firemen and policemen ride free. However, the city may use its proportion of divisible excess profits for the reduction of fares, although it may not do this in such a way so as to materially reduce the amount of the company's share below a sum which the company would have received if the rate had not been reduced. (This evidently is intended to provide a certain stimulation of traffic with reduced fares to compensate for the unit reduction.)

INTERURBAN LINES, EXPRESS, ETC.—Connections with interurban lines continue as before and until changed by city ordinance on six-month notice. Such operating rights may be revoked by the city for cause. Interurban cars are to be operated in the city by city-company crews and new fares retained as on ordinary cars. For interurban connections, 15% of the amount received by interurban companies from passengers entering the city goes to the local company.

PUBLIC ACQUISITION—When the city secures right to half the system by application of its share of divisible profits, it becomes the owner, with the company holding a lien on the property for its former share. By paying the company cash for its share of ownership and by paying the cost of redeeming mortgage bonds (with 3% premium) the city may become sole owner. When the city secures half ownership as above the company loses all right to the divisible profits. Prior to this critical point the city may buy out the company by paying for capital, cost of redeeming bonds, and the value of right to participate in surplus profits.

Criticisms of the Franchise

The franchise was criticized before election on the ground that the compromise valuation included certain intangible elements which should have been omitted because they represented money lost in an admittedly speculative period of the road's development. The reasonableness of 5% was admitted by the opponents of the ordinance, but the 6% allowed was held in effect to increase the capitalization to $36,000,000.

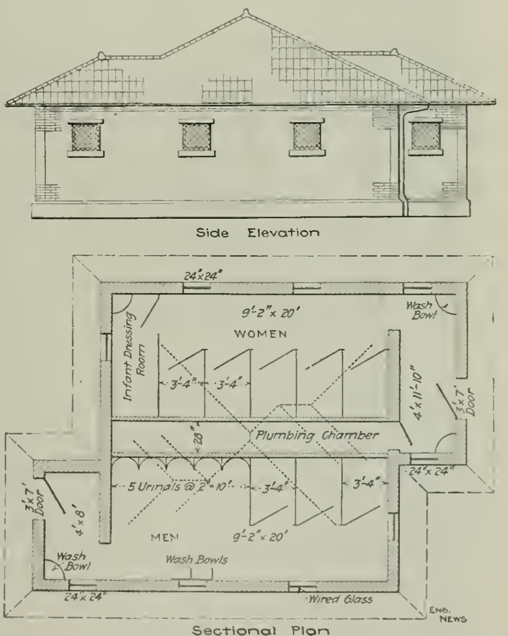
The scheme of dual control by company and city was claimed to violate every principle of good management and to tend to result in continual litigation.

Making the expenses of injuries and damages subordinate to the 6% preferential return on capitalization was attacked, it being held that these should not be separated from operating expenses, the first item to be subtracted from gross earnings.

The capitalization of betterments was criticised on the ground that the most careful maintenance and renewal will never bring the property much above Mr. Arnold's finding of 79% good-as-new.

A Public-Comfort Station with a New Feature

The plans herewith show a public-comfort station which will be built in the city of Youngstown, Ohio. The designs were made in the city engineer's office (F. M. Lillie, City Engineer; L. T. Fawcett, assistant engineer



Floor Plan and Side Elevation, Lincoln Park Public-Comfort Station, Youngstown, Ohio

in charge of the design). The plans show an arrangement similar to that used elsewhere, but with an interesting addition in the shape of an infant's dressing room, which is partitioned off from the women's compartment.

Brick walls, tile roof on wood roof-framing, a brick main dividing wall, and concrete floors, form the shell of the structure. The interior partitions will be of wood, as unfortunately the appropriation happens to be too small to provide slate or other fireproof partitions.

The design secures what is believed to be a structure of excellent appearance at a low cost. The cost is estimated at $2500, of which the plumbing makes up nearly $1000.

Recent Developments in Granite-Block Paving

SYNOPSIS—This article summarizes the evolution which has taken place in granite-block paving practice and gives the new specifications adopted by the Committee of Consulting Engineers of the City of New York for work during the current season. These specifications are the product of about four years' careful study, experiment and investigation, and present the latest practice of some of the most noted pavement experts in this country.

During the past four years an evolution has taken place in granite-block paving, indeed an evolution nearly as marked in practical results as that from the old cobblestone pavement to the first squared block pavements. The granite-block pavements now being laid in New York City, Philadelphia and other large cities, are nearly as smooth as brick, less than half as noisy as the best granite block laid five or more years ago, yet retaining all the advantages which make granite block best for heavily traveled city streets. Instead of large roughly shaped blocks, 7 in. or more in depth laid with seldom less than 1-in. joints filled with sand, smaller, carefully squared blocks 4 in. deep and laid with not greater than ½-in. joints filled with a bituminous binder, now constitute first-class standard practice.

Since a concrete foundation for first-class granite-block pavement has become universal practice the necessity for the large-sized blocks has disappeared. The blocks themselves instead of constituting the whole pavement are now made to serve as a wearing surface only, as with asphalt and wood block. The more accurately shaped blocks laid with small closer joints are the result of a determination by pavement experts that the additional expense of about $1 per sq.yd. for the pavement is justified by the improved wearing qualities, better appearance and other advantages obtained by the new specifications. The present cost of the new type in New York City varies from $4 to $4.75 per sq.yd., including a 6-in. concrete foundation.

The closer joints tend to eliminate the rounding off of the top edges of the blocks, which results in constantly widening the gap between blocks and making a rough noisy pavement, after a few years' service. The best practice is no longer to insist upon the hardest obtainable granites, but to use tough, medium-hard granite which will wear uniformly instead of those which experience has shown will acquire a polished hump in the center and rounded edges under severe traffic conditions.

Fig. 1. View of Lafayette St., New York City, Showing Example of Granite Block Paving under New Specifications

Granite block, even that laid under the new specifications, is, of course, noisier under steel tire and horse-drawn traffic than either asphalt or wood block, and it is not as easy to clean; yet its slightly roughened surface gives a good foothold for horses' hoofs and in durability it is and always will be superior to all other types of pavement, and it is the easiest to repair. It is always likely to remain the only satisfactory pavement for streets which carry a heavy trucking traffic.

During the past four years many thousands of square yards of new granite block have been used in repaving New York City streets. These have been laid under constantly improving specifications which have been redrawn and modified from time to time by conferences between the paving experts in and about New York City and the quarry men. Several inspection trips were made

by the city engineers through the various quarries in North Carolina, Massachusetts, New York, Maine, New Hampshire, where are the principal sources of granite paving blocks for New York City, in order to determine the probable output and to insure an understanding on the part of the quarry men of the requirements.

The granite-block pavements resulting from this study, care and experience are of a smoothness never before obtained. Fig. 1 shows a view of Lafayette St. near Pearl St., which is typical of these new pavements. Fig. 2 is the same pavement in the course of construction.

The final specifications for this class of work are essentially the joint product of the Committee of Consulting Engineers of the City of New York. In order to accelerate the present season's work in the Borough of Manhattan, some slight changes and additions were made in Committee's specifications, which may or may not be finally adopted by all the boroughs. As these new 1914 specifications present the experience, study and present practice of some of the best known paving experts in this country, they are of extraordinary interest and value to all municipal engineers. Of special interest are the sections relating to the joint filler; cement grout is not used; and the specifications here given for bituminous filler were especially prepared by Dr. Felix Keeberg, chemist of the Bureau of Highways of the Borough of Manhattan, after a careful study, for the purpose of making a comparative service test of the relative values of coal-tar and asphaltic paving cement.

Fig. 2. Lafayette St. Pavement during Construction

It is stated by the Chief Engineer of the Bureau of Highways of the Borough of Manhattan that the method of preparing the joint filler as a mixture of paving cement and hot dry sand has not been formally adopted by the other Borough Engineers, but is introduced in the belief that a method successfully used abroad, and which has been experimentally used in this borough on repair work during the past year with entire satisfaction, will be an improvement on the previous method of first filling the joint partly full of sand and pouring paving cement on top of it. This latter method has resulted in a ten-

Fig. 3. Old and New Granite-Block Paving at Lafayette and Pearl Sts.; Showing Care Taken to Shape Blocks around Manhole Heads on New Pavement

dency toward the use of too much sand and too little paving cement.

The specified foundation is a 1:3:6 gravel or broken-stone concrete, 6 in. thick.

GRANITE-BLOCK PAVEMENT

SECT. 1. EXCAVATION AND FOUNDATION—The roadway shall be brought to a uniform subgrade, and shall be rolled with a steam roller until the surface is thoroughly compacted. Portions of the roadbed inaccessible to the steam

FIG. 4. OLD AND NEW GRANITE-BLOCK PAVING, LAFAYETTE AND PEARL STS.

roller shall be ... with a small ...

[illegible]

from this width, and within the limits for width of blocks specified above.

For use in street railway tracks the blocks may have a maximum length of 11½ in., the other dimensions remaining the same as specified above.

When approved by the engineer the blocks may be of such other dimensions as special construction may make necessary.

DRESSING—The blocks shall be approximately rectangular on top and sides and uniform in thickness. They shall be so cut that the joints between individual blocks when laid shall average not more than ⅜ in. The head of the block shall have no depression greater than ¼ in. from a straight edge laid in any direction and parallel to the general surface of the block.

HANDLING—Care shall be used in handling the blocks so that the edges and corners are not chipped or broken.

SECT. 4. SELECTION—The stones from each quarry shall be piled and laid separately in different sections of the work and in no case shall the product of different quarries be mixed.

SECT. 5. INSPECTION BEFORE DELIVERY—The paving blocks will be inspected at the quarry or at the dock as unloaded; and if the percentage of blocks failing to conform to these specifications found in 1000 blocks, as unloaded, shall exceed 15%, the whole cargo will be condemned and will not be used on the work.

If permitted by the engineer the percentage of unsatisfactory blocks may be determined from the examination of another 1000 blocks, but if this is permitted, before delivery

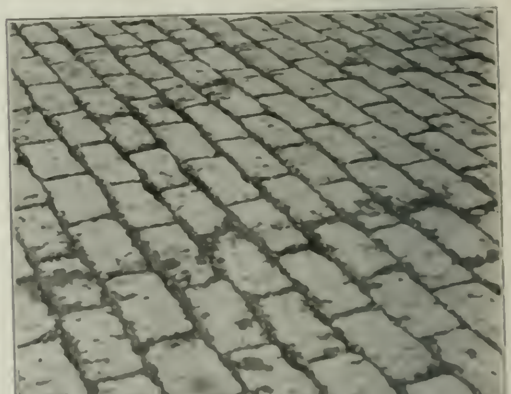


FIG. 5. GRANITE-BLOCK PAVEMENT IN FULTON ST., NEW YORK CITY, LAID IN 1912, WITH ½-IN. JOINTS—AN INTERMEDIATE STAGE IN THE DEVELOPMENT OF BETTER GRANITE-BLOCK PAVEMENTS

on the street the unsatisfactory portion of the cargo shall be removed and not delivered on the work.

Acceptance of a cargo as described will not be considered as acceptance of all individual blocks and the engineer and his assistants will have the right to reject any block at the site of the work not conforming to the requirements of the contract.

SECT. 6. FOUNDATION CONCRETE SURFACE—The top of the concrete foundation shall be brought, by screeding or otherwise, to a grade which shall not vary from ¼ in. [illegible]

any point from a surface parallel to and 6 in. below the finished surface of the pavement.

SECT. 7. SAND BED—On this concrete shall be laid a bed of clean, coarse sand, free from gravel, over ⅜ in. in diameter. The bed shall not exceed 1 in. in thickness and be sufficient to bring the surface of the pavement, when thoroughly rammed, to the proper grade.

SECT. 8 LAYING BLOCKS—Upon this bed the blocks shall be laid in straight courses from curb to curb and at right angles to the lines of the street, except when otherwise directed by the engineer. The grade and crown shall be as shown on the plan or as directed. End joints shall be broken by a lap of at least 3 in., and adjoining stones in the same course shall not vary more than ¼ in. in width. The blocks shall be set in contact at end joints and with side joints as

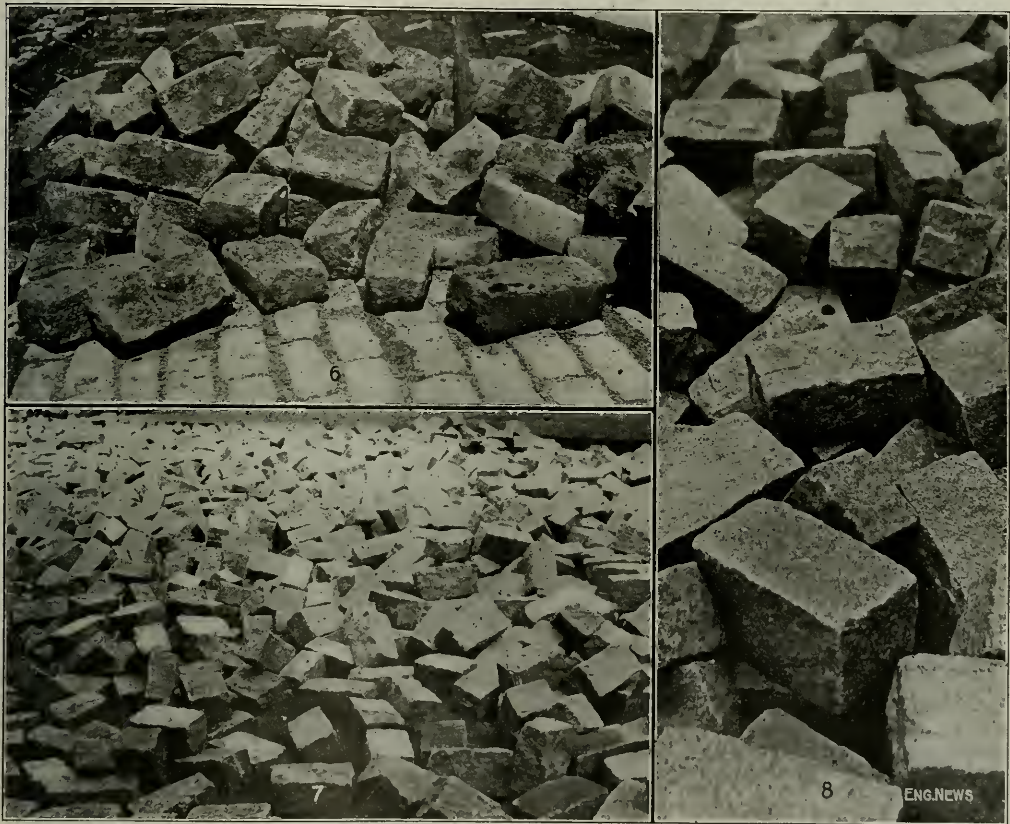

Fig. 6. Pile of Old-Style Granite Blocks

Figs. 7 and 8. New Granite Blocks, Jane St., New York City; Illustrating More Regular and Uniformly Shaped Blocks Required by New Specifications

nearly uniform as practicable and averaging not more than ⅜ in. between individual stones.

Guide blocks or head stones shall be set at such intervals as directed by the engineer.

SECT. 9. RAMMING AND ADJUSTING—After the blocks are laid they shall be rammed to a solid bearing, any low blocks being taken out by means of tongs and raised by adding sand to the bed, and the whole rammed again to a fair and even surface. No sand shall be placed in the joints, but, if permitted by the engineer, a small quantity of clean, dry sidewalk grit may be put into the joints, in amount only sufficient to pin the blocks and prevent them from rocking. The joints shall be adjusted and unsatisfactory blocks taken out with tongs. No pinch bars shall be used except by special permission of the engineer. No sand shall be placed in the joint except when mixed with bituminous filler as specified hereafter.

A sufficient number of rammers shall be employed so that all pavement laid may be rammed and joints filled before work ceases each day.

SECT. 10. JOINT FILLER—The joint filler used shall be a mixture of paving cement, described hereafter, and hot dry sand in the proportion of 1 part sand to 1 part paving cement by volume, or as much sand up to that proportion as the paving cement will carry. The sand shall be clean and sharp, and all of it shall pass a 10-mesh screen. It shall be thoroughly mixed with the paving cement by stirring or otherwise.

The mixture shall be poured into the joints until they are full and remain full, repouring being done if necessary so that they shall remain permanently filled flush with the surface of the pavement.

SECT. 11. COAL TAR PAVING CEMENT—The coal tar paving cement shall be a straight run residue obtained from the distillation of coal tar and shall comply with the following requirements:

(a) Melting point shall be not lower than 110° F. nor higher than 125° F.

(b) Free carbon shall not be less than 20% nor more than 35%.

(c) Specific gravity at 77° F. shall not be less than 1.22 nor more than 1.30.

(d) Specific gravity of the distillate to 670° F. shall not be less than 1.06 at 110° F. compared with water at the same temperature.

The contractor before beginning work on any contract shall obtain from the engineer a statement in writing as to the melting points desired for that particular contract and a variation of 5° F. either way will be permitted from this melting point, but within the limits as indicated above.

SECT. 12. THERMOMETERS IN KETTLES—The kettles in which the coal tar paving cement is heated on the street shall be equipped with approved thermometers and the paving cement shall be heated to a temperature of not less than 2[illegible]° F. nor more than 3[illegible]° F. and shall be poured when between these limits.

FIG. 9. DIFFERENCE BETWEEN OLD- AND MODERN-DRESSED GRANITE-BLOCK PAVEMENTS ON MARKET ST., PHILADELPHIA, PENN.

SECT. 13. ASPHALTIC PAVING CEMENT—The asphaltic paving cement shall be obtained by the distillation of an asphaltic petroleum at a temperature not exceeding 700° F., and shall comply with the following requirements:

(a) It shall be homogeneous.

(b) Melting point shall not be less than 130° F. nor more than 14[illegible]° F.

(c) Solubility in carbon tetrachloride shall not be less than 99[illegible]%.

(d) Penetration at 77° F. shall not be less than 60 nor more than 1[illegible], the penetration test being made with a No. 2 needle for five seconds under a load of 100 grams, and the penetration at 1[illegible]° F. shall not exceed three times the penetration at 77° F., the condition of time and load being as above established. The contractor before beginning work shall obtain from the engineer a statement in writing as to the penetration desired for any particular contract and a variation of not greater than ten points either way from this penetration will be permitted.

(e) Ductility at 77° F. shall not be less than 40 cm. at the penetration called for.

(f) It shall not lose more than 3% by volatilization when maintained at a temperature of [illegible]° F. for five hours, nor shall the penetration of the residue, after such heating be less than one-half the original penetration.

SECT. 14. THERMOMETERS IN KETTLES—The kettles in which the asphaltic paving cement is heated on the street shall be equipped with approved thermometers and the paving cement shall be heated to a temperature of not less than [illegible]° F. nor more than [illegible]° F., and shall be poured when between these limits.

SECT. 15. All tests will be made in accordance with the [illegible] Methods of Tests on file in the office of the engineer.

SECT. 16. [illegible]—The appliances for [illegible] the materials for filling the joints shall be of such [illegible] as will permit the [illegible] to [illegible] and all joints of [illegible] shall be [illegible] before the [illegible] of work for the day.

SECT. 17. [illegible] TRAFFIC [illegible]—No traffic of any description shall be permitted on the pavement until the joints have been completely filled with the bituminous [illegible], and it has had time to harden.

SECT. 18. MORTAR UNDER RAIL HEAD—Where there are car tracks in the street the spaces between the web of the rail and the paving blocks and directly under the head of the rail shall be filled with a stiff mortar, composed of 1 part of portland cement and 3 parts of clean sharp sand. This mortar shall be carefully struck so that it will not project beyond the vertical plane of the edge of the rail head, and it shall be kept in position until the paving has been laid. This mortar furnished and placed will be paid for at the price bid for concrete within the railroad area.

SECT. 19. REPAIRS AND RESTORATIONS—In making repairs to the pavement, or restoring the pavement over openings, the materials used shall conform in all respects to the requirements for the original pavement. The adjoining pavement and foundation and so much of the earth under the foundation as may be necessary and directed shall be removed by the contractor for the proper restoration and repair of the pavement. The concrete base shall be removed for a distance of 6 in. beyond the extreme limits of the area of earth disturbed. All joint surfaces of concrete shall be cleaned and coated with portland cement grout, and the wearing surface of the pavement shall be replaced over an area extending at least 3 in. on all sides beyond the area of the new concrete, all courses being toothed or racked back.

The price for restoring the pavement shall include the cost of all materials and labor necessary to properly complete the work as described above, and the maintaining of the same during the remainder of the period of maintenance.

SECT. 20. CONTRACT PRICE TO INCLUDE—The price bid for granite paving shall include the cost of all materials and labor necessary to furnish and lay the granite paving complete, and the cost of adjusting and bringing to the new lines and grades such curb and flagging and abutting pavements as may be deemed necessary by the engineer, except as otherwise provided, and maintaining the pavement for one year.

FIG. 10. LAYING A "NIDGED" GRANITE-BLOCK PAVEMENT IN GLASGOW, SCOTLAND

(From a photograph taken in July, 1911 by Geo. W. Tillson, Consulting Engineer, Borough of Brooklyn, New York City.)

The excellent results obtained under these specifications in the Borough of Manhattan, New York City, are no less due to the better quality of materials used than to the more rigid and efficient inspection system developed under the administration of the present Chief Engineer of Highways, H. W. Durham.

Inspectors are instructed to select blocks of uniform width and depth for each course and to see that each block

is laid on a full bed of sand and struck in at the base so as to bring the stone in contact with its neighbors in the preceding course, which insures the closest possible joint. The inspectors are also instructed to see that the joints in the line of traffic are close and that the alignment of the courses is true. The operation of ramming is not permitted to approach within 20 ft. of the paving. After ramming, the pavement is backrammed whenever the surface looks uneven.

Under the new Pittsburgh, Penn., specifications recently put into effect, new stone-block pavements are laid with blocks from 5 to 5½ in. in depth, on a sand cushion 1½ to 2 in. thick, and with joints filled either cement grout or bituminous material. The total thickness of the completed pavement including 6 in. concrete base is to be not less than 13 in.

During the last year the first pavement of this type was put down in Philadelphia on Market St., and W. H. Connell, Chief of the Bureau of Highways, in his recent report has this to say regarding the new pavement: "The new type of granite block forms a pavement almost as smooth and easily cleaned as asphalt, yet sufficiently durable to withstand the wear of heavy traffic."

In Great Britain, paving engineers have occasionally gone even further in specifying regularly shaped blocks. The accompanying illustration, Fig. 10, is from a photograph taken in Glasgow, Scotland, in July, 1913, by George W. Tillson, Consulting Engineer of the Borough of Brooklyn, New York City, who gives the following explanation:

"The blocks were what they called nidged, that is, they were dressed. As a matter of fact, as can be partially seen in the picture, the blocks were dressed on all sides but the bottom, and fine axed on the top. The pavement was the best I have ever seen but cost $6.25 per sq.yd. It was located on a street-car street and replaced an asphalt pavement which had been down for about ten years."

A Notable Decrease in Electric-Railway Traffic Resulting from Increased Fare

In December, 1911, the Hudson & Manhattan R.R., which operates two pairs of electric-railway tunnels between New York City and New Jersey communities, raised the fare on the northerly, or uptown, tube from five to seven cents. The changes in traffic resulting from this move are reflected in the traffic figures regularly reported to the Public Service Commission for the First District of the State of New York and published in its regular reports.

Ticket sales at stations on the northerly line in question uniformly showed a marked decrease for each month in 1912 compared with a corresponding period for the year before, and this decrease continued, though perhaps not quite so markedly, during 1913. For 1912 the general decrease of 17.6% (15,723,000 to 12,956,000) is to be compared with an increase of 22.8% for 1911. For 1913 the uptown traffic dropped to 12,295,000, a further loss of 5.8% from the 1912 figures.

The southerly, or downtown, tubes showed an increase of 28.2% for 1912 (12,090,000 to 15,498,000), compared with 9.5% increase in 1911 over 1910. Much of this, however (the rise from 216,900 to 1,020,000), was due to joint-line operation over the Pennsylvania R.R. to Newark. Deduction of joint-line tickets results in a decrease of 2.9% for 1912 in place of an increase of 6.6% for 1911. For the calendar year 1913, the total downtown traffic was 22,430,000, an increase of 44.7%. Of this, 5,568,000 was due to joint-line tickets, and the strictly tube traffic was 16,861,000, an increase of 47.4%.

It is seen, therefore, that the slump in regard to the downtown tube was only temporary and is not easily explained; but it may be assumed that the trouble on the uptown line was due to the reluctance of patrons to pay the 40% rise in fare, so long as there existed reasonable ferry and surface lines.

In the 1912 report of the Public Service Commission there is an interesting estimate of the probable loss of revenue to the company from this move, which evidently has proved unwise. It should be noted, however, that the increase in fare was not in any sense an extortion, or even unfair, as the company's lines were of very heavy first cost and their operation under a five-cent fare was giving deficits.

The added revenue for 1912 from two-cent tickets was $509,390 (17½%), and the total number of passengers carried would have yielded at five cents a gross income of $2,903,962, but the drop in passengers carried one way meant a loss, at the old rate, in round-trip fares of $276,730, not considering the normal increase in traffic manifest between 1910 and 1911 (23%). If a prospective increase as low as 15% were killed off by the new fare, then $235,850 in round-trip fares were lost to gross revenue. This added to the above $276,730 gives a probable minimum loss of $512,580 to be compared with $509,390 actual gain shown.

For 1913 the further drop of 661,000 passengers going one way meant a direct loss of $342,800 over 1911, at five-cent fares and round trips. If there would have been an increase of as little as 15% in traffic per year under the old rate, the number of passengers further lost in the second year would have risen to 4,717,000, which means a total probable annual loss of $814,500, to be set off against the $459,000 actual gain in gross revenue for 1913 over 1911 through the seven-cent fare.

In its further discussion of this situation, the Public Service Commission holds that the operating expenses of the Hudson & Manhattan R.R.—16.5c. per car mile —are too high for a rapid-transit road, yet for 1913 this has gone up to 17.4c. The corresponding figures for the subway are 10.4c. and 10.1c., respectively. The operating costs per passenger in 1912 and 1913 were 2.16c. and 2.31c.; on the subway these figures were 2.15c. for both years. The passengers per mile of track (3,500,000 in 1912, 3,494,000 in 1913) is high, but below the New York City subway (4,130,000 and 4,290,000). On account of short lengths of haul, the Hudson & Manhattan passengers per car mile is higher, 7.6 in 1912 and 7.4 in 1913, compared with 4.7 and 5.1 for the subway. The car hours per mile of track, 26,471 in 1912 and 24,015 in 1913, is held to be low compared with 45,430 and 46,300 for the subway. From such figures it is argued by the Commission that the company should have aimed to increase the density of its traffic rather than the yield per passenger. The short haul, compared with that of the subway, it is urged, allows, without overcrowding, a very dense traffic—as great as 7,000,000 passengers per track mile per year.

The Southern Alberta Land Co.'s Irrigation Project

By W. St. J. Miller*

SYNOPSIS—An extensive irrigation system near Medicine Hat, Alta., is described. There will be a composite earth and concrete dam and a concrete intake on the Bow River, a 44-mile canal leading to a large storage reservoir formed by several dams, some 45 miles more of main canal and a large mileage of laterals. About 200,000 acres will eventually be under water.

An irrigation system designed to cover 200,000 acres of land is being constructed by the Southern Alberta Land Co., Ltd. The project lies between Medicine Hat

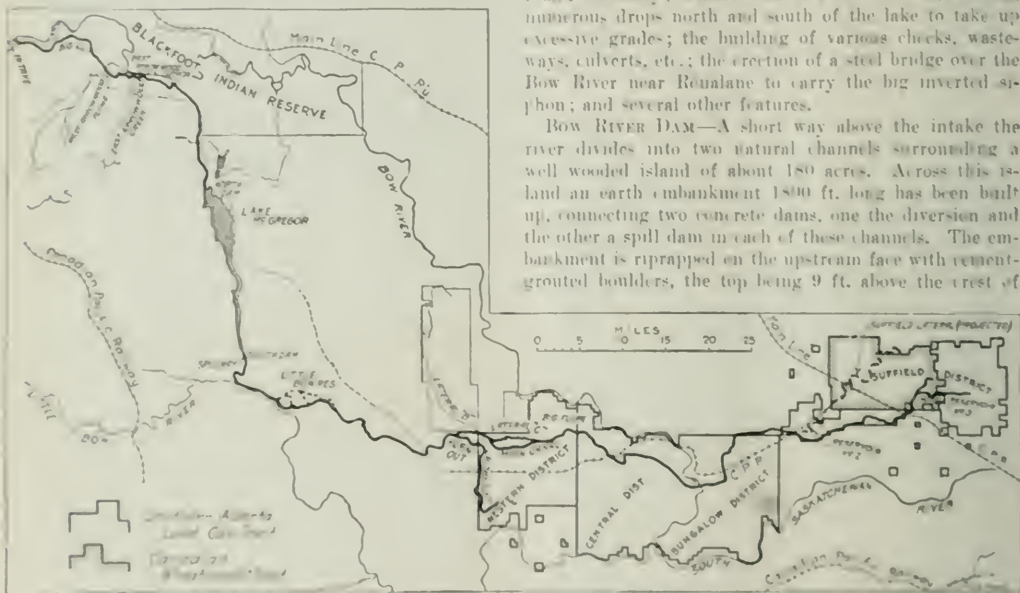

Fig. 1. General Map of Irrigation Project of the Southern Alberta Land Co.

and Calgary and to the southward of the large irrigation system of the Canadian Pacific Ry. (see the two maps, Figs. 1 and 2, for outline and general location of the scheme).

Altogether the company owns or holds options on 400,000 acres of land, of which [illegible] are to be irrigated under government requirements. Work was begun in 1909 but thus far only a few laterals have been excavated. These will be extended in 1915 so as to make possible the irrigation of [illegible] acres. The laterals will be extended as demanded.

Construction under the recently appointed Chief Engineer, D. W. Hays, was carried on vigorously during 1913. As in many similar projects, the work necessarily covers an extensive area, requiring extremely skillful executive ability, and here we evidently find the right man in the right place.[4]

Elements of the System

The main canal from the intake to Lake McGregor Reservoir is some 44 miles long; the lake itself has a length of 21 miles, and from the South Dam of the lake to the western boundary of the company's tract is a stretch of about 45 miles.

Recent operations have consisted chiefly in enlarging the original canals to care for the increased capacity found necessary; construction of a new intake; erecting numerous drops north and south of the lake to take up excessive grades; the building of various checks, wasteways, culverts, etc.; the erection of a steel bridge over the Bow River near Ronalane to carry the big inverted siphon; and several other features.

Bow River Dam—A short way above the intake the river divides into two natural channels surrounding a well wooded island of about 180 acres. Across this island an earth embankment 1800 ft. long has been built up, connecting two concrete dams, one the diversion and the other a spill dam in each of these channels. The embankment is riprapped on the upstream face with cement-grouted boulders, the top being 9 ft. above the crest of the dams. These two dams are a necessity in order to sufficiently raise the surface of the water in the river to pass into the main intake supplying the canal system.

Intake—The intake structure for the diversion of the necessary amount of water from the Bow River, not far from Gleichen, is nearing completion under the supervision of Division Engineer F. A. Wallace. This is entirely of concrete, having a floor width of 58½ ft., and total length of 206 ft. Of the total length, 123 ft. are above and 83 ft. below the gates. There are four gates, each 10 ft. wide by 8 ft. high, of the "Stoney" type, ope-

*Assistant [illegible] Engineer, Southern Alberta Land Co., Medicine Hat, Alta., Canada.

[4]The head office of the company is in the city of Medicine Hat, Alta., where a large staff of engineers [illegible]. The home office is at [illegible], London, Eng. [illegible] of Vancouver, B. C., late Chief of the Department of Irrigation Works in India, is Consulting Engineer in Canada, and [illegible] of engineering and technical adviser to the London office [illegible] as consulting engineer.

ilar to those in the Assuan Dam in Egypt. On the south side, 27 ft. above the gates, is the turnout leading the water to the main canal feeding the entire system. This inlet is 64 ft. wide and 50 ft. in length, consisting of five arched openings 10 ft. in width and 16 ft. long, with a roadway on top. The supply is regulated from a platform by the removal or addition of wooden "needles" resting inclined against horizontal I-beams spanning the five openings (Fig. 2).

Fig. 2. Headgates of Main Irrigation Canal

Fig. 3. West Arrowood Flume

The walls throughout the intake are step-battered on the outside and partly straight, partly step-battered on the inner or water side. The floor is entirely of boulder concrete except a length of 25 ft. at the piers and abutments for the gates where it is topped with a layer of hammer-dressed boulders. The floor slopes above the gates 1:50 and below the gates 1:20. A 10-in. I-beam acts as a sill on which the gates will rest. A peculiar feature of the "Stoney" gates is that the water-tight joint is on the upstream or pressure side of the gates instead of the downstream side, as is more usual. Close contact is assured by the wedging action of a system of rollers.

Fig. 4. East Arrowwood Siphon

Fig. 5. Notch Type of Drop
Fig. 6. Flashboard-Wier Type of Drop

Deep Cut—About five miles southwest of the intake the canal emerges from the river valley toward a high plateau, which necessitated a very deep cut varying from 64 ft. to about 40 ft. over a distance of 8700 ft. The cut in this section was a source of much trouble and annoyance to the contractors on account of the nature of the ground, which consists principally of gumbo with numerous sand pockets and springs, causing frequent slides.

Flumes—The next features are the flumes spanning several wide creek-beds. These are of wooden construction, carried on trestles with four-post bents 16 ft. c. to c., of a maximum height of 52 ft. The flume across the West Arrowwood Creek (Fig. 3) is 1200 ft. in length, of rectangular section, 16 ft. by 10 ft.

Inverted Siphons—The East Arrowwood Creek is spanned by a pair of inverted siphons of wood-stave construction, each $7\frac{1}{2}$ ft. in diameter (Fig. 4). These con-

nel with concrete portals at each end. Between here and the lake are two more box flumes besides a wasteway and three large concrete drops.

LAKE MCGREGOR RESERVOIR—At the northeast corner of the lake is a dam 3600 ft. long on the crest, and 48 ft. high, containing some 325,000 cu.yd. of earth. At present, it has not been decided what form of structure will be necessary to deliver the water from the main canal to the lake reservoir. This reservoir, known as the Lake McGregor Reservoir, is formed in a naturally dry coulee, 21 miles long, and at the widest part about 12,000 ft. across. Toward the southern end, the reservoir narrows down to a few thousand feet between precipitous banks. The capacity of the reservoir will be somewhere in the neighborhood of 300,000 acre-ft. There will be a concrete structure at the southern or outlet end, east and west of which will extend the existing earth dam,

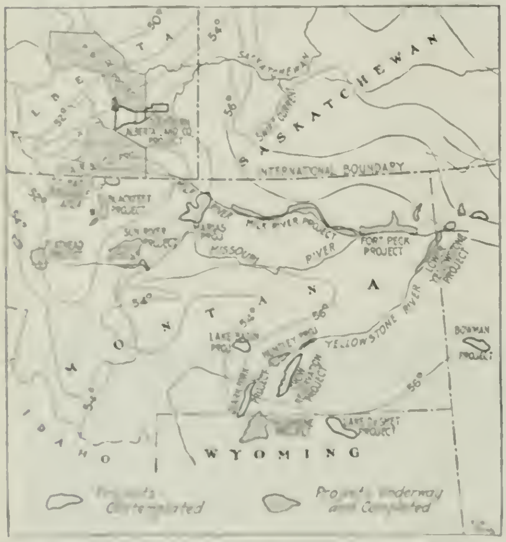

FIG. 7. SKETCH MAP OF VARIOUS IRRIGATION PROJECTS IN ALBERTA, MONTANA AND WYOMING

faced with concrete from the toe to the water level at the upstream face, only. This dam is 2100 ft. long on the crest, 40 ft. high and 85 ft. wide on the top. At the downstream toe a gravel-covered rock-filled drain is being placed to provide a drainage system for the dam.

MAIN CANAL AND CANAL STRUCTURES—The velocity in the main canal throughout the project will vary considerably, depending on the nature of the material. An average velocity of 2.5 [illegible] per sec. in natural earth to as high as 10 [illegible] in flumes or concrete sections will probably be the range.

Leaving the North Dam there is a stretch of ten miles of canal to the proposed Little Bow Reservoir, which will have a capacity of approximately 30,000 acre-ft. From here, the water will pass through an outlet structure, thence over several concrete drops to the natural [illegible] to the Alberta Land Company's lands.

One of these drops is shown in Fig. 5, which gives an idea of the size of these important structures. This particular one is of the "closed" type. The walls and floor are heavily reinforced. Concrete is mixed 1 part cement to 7 of sand and gravel, 5-in. boulders being used in the foundations and $2\frac{1}{2}$-in. boulders in the walls. The following quantities were required:

Concrete	275 cu.yd.
Steel	15.7 tons
Forms	11,000 ft., b.m.
Paving	450 sq.yd.
Excavation	700 cu.yd.
Back-fill	2900 cu.yd.

Such a drop would take about three months to build complete. Another drop of the flashboard weir type is shown in Fig. 6.

From the before-mentioned turnout the main canal crosses the company's own holdings as far as Suffield and beyond. In this section, the main features of interest are the so called "Big" or "Mile-wide-valley" flume already constructed. This is 5000 ft. long with a 16x8-ft. box, approximately 30 ft. high. A wood-stave siphon, 8 ft. in diameter, which will be 6540 ft. in length, will carry the water originally coming from the Bow River across the same river. The steel bridge to carry this siphon has six spans of 120 ft. each, resting on concrete piers. This was supplied by the Wisconsin Bridge Co., and is designed to carry highway traffic also.

This is the last of the bigger structures on the project. All that is required to be done from here to the Suffield District is the extension of the present system of laterals from the main canal as necessity requires.

A noticeable feature in this project is the part that reinforced concrete is playing. With the exception of the flumes and wood-stave pipes, all the structures are of this solid construction. In no case will the water be permitted to exceed a maximum depth of 8 ft. in canals.

As already mentioned, this description must be incomplete at the present stage of development. It, however, covers what has already been done in this important scheme to date; also the work that is under way and at present projected for completion. It will convey some idea of the size of the undertaking, and the great expense attached to a development of this character. Something like 2,000,000 cu.yd. of dirt had to be removed in the Big Cut alone, and as many as seven hundred men have been on the payroll at one time.

Division Engineer C. H. Bee has charge of all the work on the Little Bow Division, and J. E. Lloyd and H. C. Bender on the remaining two divisions, covering the Western, Central and Suffield districts.

COMPARATIVE TEMPERATURE, RAINFALL AND DUTY-OF-WATER DATA

Some interesting compilations have just been completed to determine the economic duty of water required by the farmers in this section during the irrigating season. The irrigation factor and losses by seepage and evaporation become matters of great importance in planning a system for irrigation, and it was to assist in the attainment of this necessary information that the following data were compiled.

A search was made through the statistical records of the meteorological and climatological services of Canada and the United States as far back as 1888. From these records were tabulated the yearly mean temperatures per month during the growing season, in this particular case taken from April to October inclusive. The average of these mean temperatures extending over as many years as were recorded was then obtained. In this way, a fairly

reliable mean temperature for the seven months was found for every recording station in the three Western Provinces, British Columbia, Alberta and Saskatchewan, as well as many places in Montana and Wyoming. The locations of these particular stations with their temperatures were platted on a map on which were also shown the various irrigation projects in the Northwest (see Fig. 7). By means of interpolation, isothermic lines were projected for the various degrees, from which result useful comparisons can be made.

By a similar method, a map has been compiled showing the total amount of precipitation over the same period of seven months. This total for each town is an average of the total rainfalls extending over as many complete years as it was possible to obtain. Isoplethic lines were interpolated in exactly the same manner as was done for the isotherms.

These maps prove very useful in many ways, particularly in showing relative characteristic conditions of this country as compared with those of the northern part of the United States where irrigation projects are extensively developed. The maps also assist in determining the quantity of water required for irrigation. In certain Montana projects, a limit of 3 acre-ft. was agreed upon in the first place which has since been reduced to 2 acre-ft., and it is now conceded in the northern States that 1½ acre-ft. would be an adequate amount for proper irrigation.

A particular advantage in extensive irrigation systems where water passes slowly through many miles of main canal and lateral irrigation ditches, with the water exposed to the bright sun of long summer days, is in the amount of heat absorbed by the water. Aside from the question of applying water to a thirsty soil, its warm temperature materially aids the luxuriant growth of products of the land not otherwise attained.

Track Layouts for Industrial Plants

The design of the track layout and sidewalk connections of industrial and manufacturing plants is a matter which should be entrusted to the engineer more largely than is generally the case, but in many cases the engineer is called in simply to stake out tracks according to a prearranged plan which in many cases might be modified with advantage to the convenient and economical working of the plant.

In a paper on "Economical Design of Factory Buildings," read before the Civil Engineers Society of St. Paul, W. E. King (Secretary of the Toltz Engineering Co.) referred incidentally to the desirability of the proper study of the sidetrack requirements. This paper is published in the June number the *Journal* of the Association of Engineering Societies (St. Louis, Mo.), and is followed by a discussion on the particular point noted above by George H. Herrold (St. Paul). An abstract of this part of the paper and the discussion is given below:

Mr. King—The track should be long enough to hold as many 40-ft. cars as the factory will need to load and unload in any one day. In isolated places, where the cars are not set so often, it must be long enough to allow for all the unloading and loading between each setting by the switch engine. Sidetracks for loading and unloading should be level. The rules of the railway, of the state and interstate railway commissions, and the state labor laws, are determining factors in the amount of room required for sidetracks.

Plans of the proposed sidetrack connection should be submitted to the railway, and assurance obtained that it is willing to put in the desired connection. If the sidetrack must cross the public road it is well to make sure of the necessary permit before putting money into the lot.

Mr. Herrold—One of the problems in connection with factory construction is trackage. It has fallen to my lot in several instances to design a track layout for factory and industrial enterprises, and I have been impressed with the fact in many cases that neither the architect, engineer nor owner had given the matter of trackage any thought, relying on the supposition that after the land had been purchased and the building was up the tracks could be got to it in some way. This is a serious oversight, as an important factor in the success of an industry is the quick and economical handling of the raw material to the factory and the finished product away from it.

In designing such trackage the engineer must not only be familiar with the daily car requirements of the factory, but also with railway switching methods in general and the particular switching services which can be obtained from the company which will handle the cars. It would be exceptional conditions which would permit of more than two switches per day; one in the morning to place the cars and one in the afternoon to remove them. Railway companies do not have switch engines waiting to place a car or remove a load whenever desired.

My experience leads me to believe that designers of factories have little conception of permissible grades or curvature for practical switching. Their plans often result in requiring additional land for right-of-way and a longer track than necessary, and even the building of trestle work or the making of excessive fills in order to bring the track to the factory at the proper level and give the length of track along the factory which should be level to permit shifting of cars during the day by hand.

The common factory switch costs approximately $185 in place; track, 82c. per running foot; low trestles, $9 per running foot, and grading for the roadbed about 20 to 50c. per running foot, per foot of fill. These items of cost and the running maintenance should be taken into consideration. Then there will be monthly bills from the railway for patrol and track repairs, even on the factory's own track, if the railway company is to operate its switch engines over it.

The simplest trackage possible is one switch and a stub-track running along the factory. This may serve the purpose for small outputs, but in general a double-end track is more desirable, as it facilitates the handling of the cars. No switching can be done on a stub track without disturbing all the cars, and this will stop the loading and unloading of the cars at the factory during the switching operations. With a double-end track, cars can be set in from one end and taken away from the other. If the business requires a different class of cars for the finished product than for the raw material, then the empties and loads can be placed at the factory doors in the morning, in the order required, and the loads and empties removed from the other end of the track in the afternoon without disturbing any cars not yet unloaded or being loaded.

Where the business is large enough, two more tracks are preferable. One track should run on each side of the factory; one for raw material loads only and the other for loading and out-going loads only. In general, each track should have a car capacity (between the clearance point of switches) equal to twice the number of cars to set on it. This permits the moving of the entire string of cars past the factory by hand, using a pinch-bar or car-puller between regular switching. A factory of this size should be designed to begin its processes on one side of the factory and deliver the finished product on the other side ready to be loaded into the cars in order to eliminate cross handling.

Track scales and track must be considered. Scales should always be under cover, and where possible on a separate track from the loading and unloading track. If the factory track should be on a curve, the scale track must be so built as to provide a straight track on the scales and for 40 ft. on each side, and if the same track must be used as a thoroughfare track then dead rails must be provided. These two latter provisions are required by the Minnesota Railroad and Warehouse Commission.

The cost of transportation of raw materials to the factory and the cost of distribution are largely affected by trackage facilities, and closer attention to this phase of the problem may save years of grief. A first-class factory poorly located with reference to trackage, resulting in awkward switching facilities, is only half a factory.

Continuous-Rail Crossing for Track Intersections

The severe wear and high maintenance cost of track intersections, especially under modern heavy railway equipment, makes it very desirable to substitute a con-

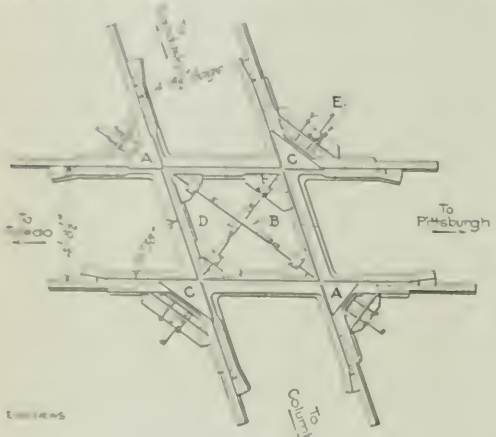

FIG. 1. PLAN OF CONTINUOUS-RAIL CROSSING
J. H. EYMON, MARION, OHIO, INVENTOR

tinuous-rail crossing frog for the ordinary frog, providing a satisfactory device is available. The devices so far designed are of two types, having sliding and revolving blocks at the rail intersections. A continuous-rail crossing which is now being tried in service is of the sliding type, each corner of the crossing having a movable block whose lateral motion (diagonal to the track centers) gives a continuous rail for one or other track. The construction and the operating mechanism are very simple.

In the plan, Fig. 1, the two sliding blocks (A) are moved by the operating rod (B), while the two blocks (C) are moved by the rod (D). The rods are connected for simultaneous movement, and if the crossing is equipped with signal interlocking plant they are connected up with the interlocking mechanism. The two smaller rods (E) at each block are the bolt blocks for locking the blocks in whichever position they are set. Each of the operating rods is cranked horizontally at each end, and this part of the rod passes through a sliding cam in the base of the crossing block. Thus a longitudinal movement of the rod shifts the blocks in a direction laterally to that of the rod and diagonally to the center lines of the tracks. Turnbuckles on the rods permit of adjustment of the throw.

The operation will be understood clearly from Fig. 2. Here the crossing is set to give continuous rails for the track running from left to right. When the other track is to be cleared, the throw of the lever gives a stroke to the flat operating rods and the blocks move in a diagonal direction upward (from the bottom of the view) and outward. This movement clears the flangeways of this second track and closes those of the right and left track. The two round rods behind each sliding block are those of the locking mechanism, and they partly conceal the ends of the operating rods.

The crossing shown in Figs. 1 and 2 is at the intersection of the main track and Sandusky branch of the Toledo Division of the Pennsylvania Lines, at Carrothers, Ohio. It is built to conform to the 85-lb. rails of the Am. Soc. C. E. section, and has a flangeway or throat width of $1\frac{3}{4}$ in. The entire crossing is of manganese steel, and is built in four sections, as shown. There are 28 trains daily on the Toledo branch and 32 trains on the Sandusky branch, and it is safe to assume that the crossing is thrown once for each of these trains. Besides this, Carrothers is a setting-off point, so that nearly every train switching there passes over the crossing at least twice in addition to its regular movement.

This crossing was built by the Indianapolis Switch & Frog Co. (Columbus, Ohio) for the Eymon Continuous Crossing Co., of Marion, Ohio. The inventor is J. H. Eymon, of Marion.

FIG. 2. CONTINUOUS-RAIL CROSSING ON THE PENNSYLVANIA LINES AT CARROTHERS, OHIO
(The crossing is set for the track from left to right.)

Cast-Iron Pipe with Screw-thread Joints has recently been put on the market by Jas. B. Clow & Sons of Chicago. The screw threads are cut on the lengths of pipe by dies similar to those used for threading wrought-iron pipe. Cast-iron couplings are used and the entire pipe line is thus kept homogeneous. This pipe is claimed advantageous, therefore, for locations where ordinary wrought iron or steel pipe suffers seriously from corrosion. It is stated that the cast-iron pipe is already being used for waste drains in [illegible] and [illegible] to steam heating [illegible].

Cantilever Span of the Bloomfield Viaduct, Pittsburgh

The Bloomfield Viaduct, Pittsburgh, will create an important line of communication across Junction Hollow, a ravine through which the Pennsylvania R.R. and the Pittsburgh Junction R.R. (B. & O.) enter from the bank of the Allegheny River at 33rd St. The viaduct is located on the line of Ridgway St., and will connect Grant Boulevard on the south, or city side, with Liberty Ave. at Main St. on the north of Bloomfield side.

The Dravo Contracting Co. built the piers, for about \$85,000, and the Fort Pitt Bridge Works is fabricating and erecting the superstructure, for a price of about \$255,000. The cost of land, \$75,000, and paving, \$15,000, will bring the total cost to near the appropriation of \$500,000.

The viaduct is a deck-cantilever structure with 400-ft. main span. It crosses about 185 ft. above the lower railway tracks (P. J. R.R.), and descends on a steady grade of 3.9% from south to north. The total width is 50 ft., with 34-ft. roadway. A uniform paneling of 20 ft. is used throughout the length of the steelwork, including the 20-ft. tower spans. The total length of superstructure is 1740 ft. 10 in., but retained embankments at the ends bring the total length up to 2099 ft.

The long north approach contains eight 60-ft. plate-girder spans and two 120-ft. truss spans; then follows the cantilever structure with 120-ft. anchor arms, 20-ft. towers, 140-ft. cantilever arms, and 120-ft. suspended span; the south approach has one 120-ft. truss span and two 60-ft. girder spans. The steel erection is being handled by a gantry cantilever traveler on each end. Derricks set on the approach spans raise the material from street level to the deck and feed it forward to the travelers.

The general and detail design of the bridge was made in the city's Bureau of Construction, under N. S. Sprague, in direct charge of T. J. Wilkerson, Engineer of Bridges.

Reconstruction of the Queensboro Bridge

The Queensboro or Blackwells Island Bridge over the East River, connecting East 60th St., Manhattan, with Queens Borough, New York City, is to have its floor system and deck arrangement partly reconstructed. Plans were recently submitted by the city's Department of Bridges to the Board of Estimate. The reconstruction is for the purpose of accommodating the new rapid-transit lines which are to cross the bridge.

The bridge is a cantilever structure having two channel spans of 1180 ft. and 984 ft., respectively, with an intermediate or anchor span of 630 ft. over Blackwells Island. It was completed in 1908, but its two decks were left in a condition different from that contemplated in the design. The arrangement as built is shown by the diagrammatic cross-section, Fig. 1. In the original design, the upper deck was to carry four rapid-transit railway tracks between trusses and footwalks bracketed outside; the lower deck was to carry four trolley tracks and a central roadway as shown in Fig. 1.

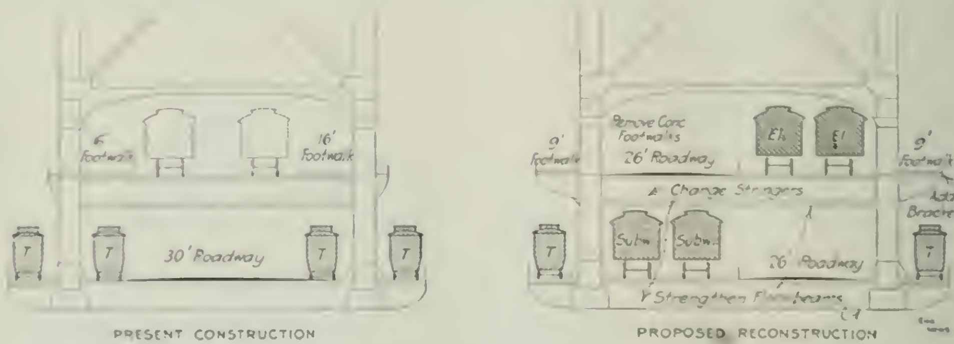

Fig. 1 Fig. 2

CROSS-SECTIONS OF QUEENSBORO (BLACKWELLS ISLAND) BRIDGE, SHOWING PROPOSED REARRANGEMENT

Shortly before the bridge was completed, grave doubts arose over its strength, largely in consequence of the collapse of the Quebec bridge some months before. The weight of the Blackwells Island Bridge greatly over-ran the dead-load assumed in the design, and the members were proportioned for maximum probable traffic rather than maximum possible congestion. Investigations of the strength of the bridge were made for the Department of Bridges by Boller & Hodge and W. H. Burr separately, and the results (reported in ENGINEERING NEWS, Nov. 19, 1908, pp. 556-558) indicated that four rapid-transit lines would overstress the truss members seriously. Partly as a result of these doubts and investigations, the upper deck brackets were omitted, and sidewalks were constructed on the outer set of upper-deck stringers, as shown in Fig. 1 (the construction of these sidewalks was described in ENGINEERING NEWS, Jan. 28, 1909, pp. 94-95).

As the plans of the Public Service Commission call for four rapid-transit tracks across the bridge, it is now necessary to make some rearrangement. However, the adoption of the original deck plan, or of any plan giving only 30 ft. roadway, is strongly opposed by inhabitants of the Borough of Queens who claim that vehicle traffic absolutely demands a full deck width of 52 ft. Further, it is inconvenient to carry to the upper deck the subway trains approaching the bridge from the west in tunnel.

The plan now proposed meets these demands by using half of the lower deck and half of the upper deck for roadway (thus giving two 26-ft. roadways), placing two subway tracks on the other half of the lower deck and two elevated-railway tracks on the upper deck and taking care of the trolley tracks and the footwalks on brackets. All this is represented by the sketch, Fig. 2.

No member of the main trusses of the bridge will require to be altered for this reconstruction. The following changes will have to be made, however: The footwalks removed; brackets attached outside the upper deck and new (narrow) footwalks built, with a board floor instead of a heavy concrete floor; two sets of the upper-deck stringers removed and roadway stringers substituted; the other pair of upper-deck stringers shifted slightly to suit 10-ft. rapid-transit cars; some upper-deck floor-beams strengthened; the lower-deck roadway and the two inner trolley tracks removed and a roadway built on half the width; on the other half width, roadway stringers removed and subway-track stringers substituted; and the lower-deck floor-beams strengthened.

The loadings now used by the Department of Bridges and the loadings used in the design of the Blackwells Island Bridge are: Trolley, 1160 lb. per lin.ft. (formerly 1000); elevated railway, 1810 (formerly 1700); subway, 2000 (formerly elevated-railway loading). Also, for the present purpose a live-load of 40 lb. per sq.ft. of sidewalk is considered justified, because with such a loading and a speed of movement of 3 mi. per hr. about 10,000 persons can cross the bridge in either direction per hour, which is regarded as far beyond any possible traffic over the bridge. The chance of crowding on the sidewalks on special occasions is considered of no importance because it may be prevented by the Police Department, because it is not likely to cover the full width of the sidewalk, and because the sidewalk loading is not critical in the design or safety of the bridge anyway.

With regard to possible concentration of train-loading, the Bridge Department counts on spacing trains

apart as described below by automatic block-signals in such a way that four lines of track will not produce greater stresses (and generally lower stresses) than ordinary double-track arrangement. Using the most unfavorable position of loading which the block-signals will permit, the calculations of the Bridge Department show maximum stresses as follows:

Tension in the top chord, about 500 lb. in excess of the originally specified working-stress of 30,000 lb. per sq.in. for nickel-steel; compression, no stress attaining the value allowed by the formula $20,000 - 50\frac{l}{r}$, which is the specification formula modified by the recommendations of Boller & Hodge and W. H. Burr. The department regards the bridge as absolutely safe under the traffic loads which it will carry when rearranged as per Fig. 2. Austin Lord Bowman, Chief Engineer, reported as follows to F. J. H. Kracke, Commissiner of Bridges: "No strengthening of any member of the main trusses is necessary to allow traffic to be carried across the bridge under this plan."

Signaling the Bridge

The arrangement of block-signals on the four rapid-transit tracks will be unique: On each of the four rapid-transit tracks, block-signals will be set at intervals of about 100 ft. and each will be equipped with an automatic stop, so that trains are spaced positively. On each deck the trains will run right-handed in both directions, so that there is one eastbound track and one westbound track on each side. Calling the two eastbound tracks "parallel tracks" and an eastbound and westbound pair "opposing tracks," the following functions will be performed by the signals: Following trains on the *same track* will be spaced 3400 ft. apart.* Trains on *parallel tracks* will be spaced 600 ft. apart. Trains on *opposing tracks* will be without influence on each other except at a block section 600 ft. long in the middle of each channel span, but here the arrangement will be such that one pair of parallel trains (600 ft. apart) must pass through and out of the block before the opposing pair can enter the block.

The effect of this latter arrangement will be that the middle of each channel span, which is the portion having the greatest influence on stresses in the bridge, cannot be occupied by more than one pair of trains, and this pair at 600-ft. spacing, which is sufficient to reduce the effect to that of a single train at midspan.

The theoretical capacity of this signaling system with a speed of 29 mi. per hr. will be 45 trains per hr. per track. Allowing for a certain amount of delay for each train, a real capacity of 41 trains per hr. per track is counted on.

*At a speed of 29 mi. per hr., this distance of 3400 ft. corresponds to 88 sec. The operation in the present Interborough subway does not secure closer spacing of trains in regular service than 90 to 110 sec.

Terminals and Connections

The trolley tracks on the brackets of the lower deck will swing outward at the west approach and descend into tunnels passing west along 59th and 60th St., respectively, south and north of the two subway tunnels leading from the lower-deck rapid-transit tracks of the bridge. At Third Ave. (about 1200 ft. west of the end of the bridge approach), the trolley tunnels will have descended sufficiently to pass under the subway tunnel and will connect with each other in a transverse loop station under the roadway of Third Ave.

At the east end of the bridge the trolleys will connect directly with the Queens trolley network.

A terminal structure at the east end of the bridge will provide for the elevated- and subway-train traffic interchange. In approaching this terminal the various tracks will change their levels so as to bring the eastbound tracks to one level and the westbound tracks to another level. The lines continue thence easterly into Queens Borough.

At the west end of the bridge the Second Ave. elevated tracks connect directly with the upper deck of the bridge by a viaduct structure.

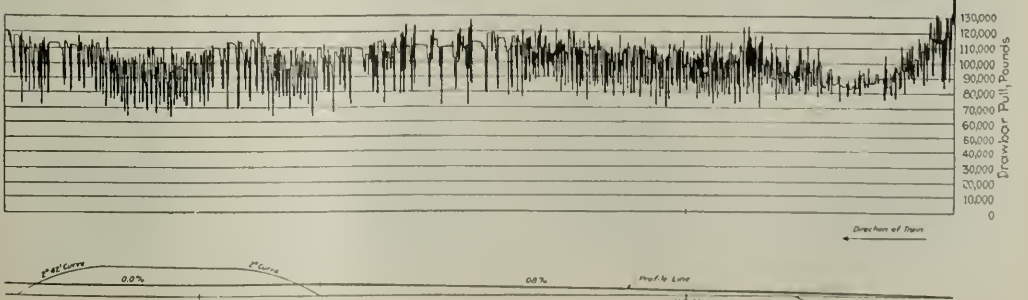
The greatest approach gradients are: Rapid-transit tracks, 5.2%; roadways, 5.8% at Manhattain end and 5.4% at Queens end. Most of the vehicle traffic at present consists of power vehicles, so that steep grades are not seriously objectionable.

The total cost of putting the bridge into shape for operation, according to Fig. 2, is estimated at $3,024,000.

F. J. H. Kracke is Commissioner of Bridges, A. L. Bowman is Chief Engineer, C. M. Ingersoll is Traffic Engineer, and E. A. Byrne is Deputy Chief Engineer.

World's Largest Locomotive Tested for Tractive Effort

The big articulated locomotive of the Erie R.R., described in Engineering News of May 7, p. 1046, was subjected to a hauling-capacity test on the Susquehanna division on July 23. The test was made from Binghamton, N. Y., to Susquehanna, Penn., a distance of about 23 mi. The locomotive was at the head of a train of 250 fifty-ton steel gondolas loaded to full capacity, and a dynamometer car. The train weighed 17,912 tons, exclusive of the locomotive, which weighed about 422 tons, and the



Typical Section of Dynamometer Record of Hauling-Capacity Test

length of the train was 8547 ft. The grade was practically level, the maximum being 0.09%, with 5° curvature.

Pushers were in readiness to assist in getting the train under way and were used in making the start from Binghamton; but at Great Bend, where the locomotive took on water, pushers were not used in starting. They pushed the slack forward until the lead locomotive had all the cars moving, after which they were uncoupled and followed the train for emergencies. Communication was maintained between the head and rear of the train by portable telephones, which made it possible for the pushers to work efficiently with the lead engine at starting. The maximum drawbar pull is shown in the accompanying section of the dynamometer record. The following tabulation gives the main facts:

Number of cars in train	251
Total weight of train excluding locomotive	17,912 tons
Total length of train	1.6 mi.
Maximum speed obtained	14 mi. per hr.
Maximum drawbar pull	13[illegible]0 lb
Minimum drawbar pull	67,000 lb.

These data were furnished by R. S. Mounce, Engineering Department, Erie R.R., New York City.

Editorials

The Effect of Increases and Decreases in Street-Railway Fares

At the last mid-year conference of the American Electric Railway and allied associations early this year, figures were presented to show that one- and two-cent reductions of street-railway fares did not result in the notable increase of traffic which some advocates of lower fares claimed would come. From the studies of the riding habit in several American cities, where reductions were to be observed, it appeared that the general business experience in stimulation of trade (directly proportional to unit-price reduction) was not followed, and the tenable statement was made that this law had a limitation when very small unit prices were concerned—as these required a much larger percentage reduction to have appreciable effect. Admitting for the moment that these figures truly reflected the habits of American riders, the converse cannot be said to be true—that increases in fare do not work a material reduction in travel. A striking illustration of this point is seen elsewhere in the discussion of the experience of the Hudson & Manhattan railroad, which operates rapid-transit tunnel lines between New York City and New Jersey. This company raised the fare from five to seven cents on one line. There was ample excuse for doing this in the continuing deficits which the company bore as the result of operations. However, the results show that it undoubtedly was an unwise move. In the first year under the increased fare there was a drop of 17.6% and in the second year a further drop of 5.8%. In the two years which have elapsed, the gross income has been increased by this raise a total of some $970,000 over what they were, but against this increase has to be set off the very probable loss of $1,300,000 gross gain which the company would have made had the traffic continued to grow at about half the rate it was growing when the new fare was put into effect. Incidentally, the traffic on this line has to compete with good ferry and surface-car service and possibly will remain some 40% below what it might be under a five-cent fare. The company has a heavy investment in tunnel construction and needs to cultivate in every way the growth of traffic.

Causes of Railway Derailments

Accident Bulletin No. 50 just issued by the Interstate Commerce Commission gives statistics of accidents occurring on United States railways during the last quarter of 1913, and shows some interesting facts regarding the causes of derailments. The total number of derailments on steam railways during the three months was 2307, but only 576 of these were due to defective roadway, while 1091 were due to defective equipment. Broken rails were responsible for 128 derailments, while 245 derailments were due to broken wheels; 102 to breaks or defects in axles or journals; 162 to breaks or defects in brake rigging, and 116 to breaks or defects in draft gear. Broken arch bars caused 73 derailments and rigid trucks 65. It is worth noting also that this quarter included the month of December, one of the winter months, when most rail breakages occur.

We have no wish to minimize the importance of measures to secure sound railway rails, free from the danger of breakage, but it is at least worth careful consideration that only one-fifth of the derailments due to defective track were caused by broken rails and that there were nearly twice as many derailments due to defects of rolling stock as to all the defects in the track. Considering the character of the labor necessarily employed in track work and the large territory that has to be covered, with the general tendency of railway financial authorities to economize as much as possible in expenditure on track repairs, the above showing is most creditable to the engineers and the men under their direction who are responsible for railway-track maintenance in the United States.

The statistics of derailments from rail breakage in the above report prove, what every railway engineer pretty well knows, that the great bulk of the steel rails in service on American railways are sound and tough and equal to the tasks imposed upon them. If this were not the case, rail breakages under the extraordinarily heavy wheel loads and high speeds common in American railway practice would be many times as numerous as they are.

This same Accident Bulletin also shows, however, that there are a few very bad rails in service. Two examples of rails of this sort are given in this report. One is a rail which broke under a freight train on the Southern Ry. in North Carolina Mar. 31, 1913, and was found after the accident to be separated into nine pieces, the shortest about 7 in. long. This was an 80-lb. rail rolled in November, 1904, and the cause of the breakage was traced to transverse fissures in the rail head.

A much more remarkable case of rail breakage, however, occurred on a coal-trestle siding in Washington, D. C., on Oct. 31 last. A Pennsylvania R.R. switching locomotive pushed some loaded coal cars on the siding and started to haul away four empty cars. It had moved barely two feet when one of the rails under it broke and the locomotive tipped over and fell to the ground 14 ft. below. The siding was laid with 85-lb. rails laid on ties two feet apart on centers. The ties appear to have been badly decayed, but this was no excuse for the rail breaking instead of bending under the static weight of the locomotive. Manifestly, such brittle rails anywhere in railway track are a dangerous menace. The chief object of those who draft specifications for steel rails and those who carry them into execution should be to prevent any such brittle and dangerous material being placed in the track.

Steam Distribution from Central Stations

The report published in our issue of July 30, on the condition of the mains of the New York Steam Co., is the first valuable technical information that has appeared for a long time concerning the distribution of steam through city streets.

In many cities of the country there are steam mains through which steam is distributed from central stations at low pressure, for heating purposes only. Usually the business is carried on by electric lighting companies, who thereby utilize the exhaust steam from their engines much more profitably than they could do by discharging it through a condenser. In New York City, however, the New York Steam Co. distributes steam at nearly 100 lb. pressure under a considerable mileage of streets in the crowded downtown business district.

At the time this plant was originally built, the distribution of power from a central station was comparatively a new development in engineering, and several systems were in competition. In some of the English cities, extensive systems of mains were laid down for the distribution of power by water under high pressure. In the United States at that time also many water companies looked with favor on the use of water taken from the city mains under pressure for operating hydraulic elevators, small motors, etc. In France the Popp system of compressed-air distribution attracted world-wide attention and was copied on a smaller scale in several other cities. Besides these systems there was the mechanical distribution of power by belts and ropes, of which the cable railway so extensively developed in the '80's was the most remarkable development.

The system of the New York Steam Co., when originally put down, was designed to compete with these other systems of power distribution. Its promoters claimed that the ready use of the high-pressure steam in existing steam-engine plants, with its availability for heating as well as power, made the steam distribution the most advantageous system; and their dream was that similar plants would be constructed in many other cities.

In the early years of operation of the New York system, very serious troubles were experienced with the street mains. The heat losses from the system were very heavy, the great amount of condensation and resulting troubles with expansion and contraction compelled the frequent digging up of the streets; and the general impression among engineers was that steam mains underneath city streets were an unmitigated nuisance.

For the past fifteen or twenty years, however, little has been heard concerning the New York Steam Co.'s operations. It has continued to carry on its business but without very greatly extending its field, and the improvements it made to its system of mains, following the troubles of twenty years ago, have seemed to obviate much of the difficulties then complained of. The report, which we printed two weeks ago, however, makes it evident that its steam mains are only less objectionable now than they were in the early days and that the difficulties experienced with them are such that were the mains not already in the streets, certainly no city government run on business principles would grant a franchise for putting them there.

It must be remembered that the earth underneath New York City's streets is already filled so full of underground pipes that it is difficult to find room for any more, especially in the narrow downtown streets where the high-pressure mains of the steam company are chiefly laid. To a certain extent, however, the above statement applies to steam mains anywhere and especially to those using high pressure. It is true that by using a much higher class of work in the laying of steam mains with ample provision for heat insulation and free expansion, it is possible to put in a system that will be much less troublesome; but such improved mains add materially to the cost of the system and experience indicates that the cost of distributing steam through city streets, at least under the conditions prevailing in New York, is so heavy that there is little profit in the business.

Of course, under present-day conditions electric power distribution has put all other systems out of the running and no engineer at the present day would seriously consider building a plant to distribute steam for power generation. Even in the distribution of steam for heating purposes, the indications are that the limitations of distance are important, and that the most successful plants are those operating in comparatively limited territory.

Finding Money to Pay for Street Paving

A good many cities are wrestling with the problem of radical improvements in their street pavements. The general use of automobiles has developed a public opinion far more sensitive to the disadvantages of poor street pavements than existed a dozen or twenty years ago. The rough stone block paving which was accepted without question in former years is now severely criticised. The public demand is for wood block, asphalt, brick, close-jointed stone block, or some other type of pavement with a smooth surface. But to substitute such pavements for the old and badly worn pavements of which every city possesses a large mileage, and to pave the miles of streets not paved at all, means the expenditure of a very large amount of money. The abutting property owners object to bearing the burden of this work and rightly so, since the large amount of traffic which an improved pavement draws to a street is an injury rather than a benefit to residence property. On the other hand, to raise money by a general tax levy for wholesale repaving would raise the current tax rates to a point which the public would not stand for. Hence a bond issue seems, in most places the only method available of raising money. On the other hand, most cities are already carrying a burden of debt which is partly made up of bonds issued to pay for pavements which have already been worn out; hence this dangerous plan of financing is properly condemned by engineers and others.

In Cleveland, Ohio, the question of what to do about the city's pavements has recently been thoroughly investigated by a citizens committee of 15, organized by a general committee made up of representatives of civic organizations. The president of the committee of 15 was Dr. Chas. S. Howe, the president of the Case School of Applied Science. Among other members of the committee were Messrs. Chas. A. Otis, James R. Garfield and Frank C. Osborn. The committee's report, which was presented on July 20, shows that of the 826 miles of

streets in Cleveland abou. 500 miles are paved. Fully one-half the paved streets need some repairs and at least 50 miles need repaving at once. The city has not been spending enough money on pavement maintenance to keep the streets in order and the pavements are growing worse every year. In addition to this, the Cleveland Street Railways Co. has neglected its obligation to keep well paved the space between its tracks and one foot on each side. These repairs were postponed while the company was engaged in its long fight over its franchise rights; and since then, the company has expended as little as possible on paving work.

The taxpayers of the city pay 85% of the road tax raised in Cuyahoga County and they pay also $407,000 each year in state road taxes. Thus the tax payers of the city pay annually over $800,000 for the building of roads outside of Cleveland.

The committee proposes to deal with this situation as follows: It recommended that the city should provide about $150,000 a year for new paving; and where streets are repaved, one-half should be paid by the property owners and one-half by the city, the total amount to be raised by the city for this purpose being about $670,000 per annum. This money should be raised by general taxation and not by an issue of bonds. The committee further recommended that efforts should be made to have the laws amended so that a part of the taxes paid by city property owners for state and county road purposes should be expended on streets within the city.

It was further recommended that a part of the funds required for repair and maintenance of city streets should be raised by the assessment of a wheel tax on all vehicles.

Still another important recommendation of the committee was that the entire work of paving, repaving and paving maintenance should be under direction of a Commissioner of Streets. Such an officer is provided for in Cleveland's new charter, but has never been appointed. The committee recommended that the Commissioner of Streets should be a thoroughly trained civil engineer who has specialized in road and pavement work and should receive a salary of at least $4500 per annum.

This is the first case on record, as far as we recall, where an organized protest has been made against the taxation of cities for the construction and maintenance of country roads. For some years past, through the development of state and county road work, the tendency has been to place upon the large taxpayers of the cities a large part of the burden of building and maintaining better country roads. That protest against this burden would be heard sooner or later was to be expected.

Through Routes Versus Terminals

The City Club, of Chicago, has just published a notable monograph, entitled "Through Routes for Chicago's Steam Railroads," which is well worth the study and careful thought of any engineer interested in the problem of city transportation. The author of the pamphlet is Mr. Geo. Ellsworth Hooker, Secretary of the City Club of Chicago. Mr. Hooker was also secretary of the Special Street Railway Committee of the Chicago City Council in 1897-8. Mr. Hooker's monograph is a quarto of some 90 pages, profusely illustrated with maps and diagrams, and to the engineer interested in city transportation is of much broader interest than the discussion of the local problems at Chicago.

The scheme which Mr. Hooker sets forth has the backing of so eminent an engineer as Mr. Bion J. Arnold. In March last, Mr. Arnold presented before the City Council Committee on Railway Terminals a preliminary study to show the possibility of applying the through-routing principle to the Chicago steam railways engaged in local passenger service.

The local passenger traffic in Chicago is now moved by surface street railways carrying 600,000,000 passengers per annum at an average speed of 9 miles per hour, elevated railways carrying 164,000,000 passengers at an average speed of 14 miles per hour, and suburban steam railway lines carrying 42,000,000 passengers at an average speed of 24 miles per hour. Mr. Hooker argues that a much larger proportion of the local railway traffic should be carried by the steam railway lines, which, by the way, he assumes are shortly to be altered to electric traction.

It is, however, impossible in Chicago's densely crowded central district to find the room for the large amount of rolling stock which would be required if the suburban steam railways run into the present crowded terminals in and close to the business distrct. Mr. Hooker urges, therefore, that there should be through routing of this local passenger traffic. For example, a steam railway train leaving the northern suburb of Evanston should not be stopped and turned to retrace its journey when it reaches the station in the central district, but should continue on southward to Hyde Park or some other farther point in the southern suburban zone, where it can be stopped and turned to retrace its through journey. Mr. Hooker discusses the principle of through routes in connection with other cities as well as Chicago, such as New York, Boston, Paris, London and Berlin, and considers its application also to street railway traffic. It is this latter feature we believe which most deserves the attention of engineers.

The electric street railway system in most American cities, unfortunately, has been developed without very much system or plan. The question on what streets it should be located has depended much more upon the prejudices and inclinations of the property holders in that street than upon the need of good service for the whole city. There has, however, grown up in most cities a system under which all or nearly all the street railway lines radiate from the various suburbs to some point in the business center, and in numerous cities the congestion in the business center as a result now presents a serious problem.

Boston, with its narrow and crooked streets, was the first American city to feel that problem in an acute form and the construction of the first Boston subway was the result. New York City has had for more than a score of years an aggravated case of crowded terminals in the center of the city at the Manhattan end of the old Brooklyn Bridge. A similar congestion once existed at the Brooklyn end of the same structure and millions of city money was used to obtain additional room for the Brooklyn terminal of this bridge. When through routing of cars across the bridge was established, the Brooklyn terminal crush disappeared as if by magic.

As we have remarked above, there are numerous cities

in which the problem of the congestion of street cars in the center of the city has become a very serious matter. We have in mind one city of a half a million population where the crowding of passengers on the cars all day long and not in the rush hours merely is nothing short of scandalous. Such conditions would not be permitted for a single day on a street railway in any city of Germany or England. The management of the company, which has long been notorious for its inefficiency and absolute disregard of public necessity and convenience, has long made the stock excuse that the crowded condition at the business center prevented the running of any more cars. It has at last awakened to the fact that the congestion on its lines is seriously limiting its traffic growth and so delaying the movements of its cars as to materially cut down its earnings, and it is therefore proceeding to invest a very large sum of money in the construction of a great terminal passenger station and car depot near the center of the city. The value of a reservoir of cars at this point is debatable, but it seems likely that the congestion above referred to might have been remedied at a small part of the cost by intelligent through routing of cars.

It will not escape notice that this principle is of even broader application. One reason for the vast reduction of transportation costs that has taken place in the last fifty years has been the steady development of through routes for both passengers and freight. The consolidation of railways into great systems thousands of miles in extent has put an end to the changing of cars and the shifting of loads every hundred miles, or less, which was common in the days when a multitude of little railway companies owned short lines in New England and the Middle States. In fact, in all manufacturing and transporting fields the effort is to make the process continuous.

Letters to the Editor

Window Protection More Important than Structure in Fireproof Buildings

Sir—Your article, "A Real Fireproof Building," in the July 16 number does not sufficiently emphasize the fact that what saved the reinforced-concrete storehouse was its small windows with their double-protection wire-glass in metal frames plus inside automatic shutters. The reinforced concrete had nothing to do with its salvation. The concrete walls are cracked in many places and the reinforcement is exposed in a few places but some of the cracks were apparently present before the fire.

Given this double window protection, a brick building, even with wood-posted construction, would have resisted the fire just as well—a fact proved by the unscathed condition of the boxes just below the windows inside, and the sprinkler heads 3 ft. away from the windows which did not go off. It should be noted also that the very small windows and the inside shutters hinged at the top to swing down would be impracticable for buildings like factories, office buildings and stores.

The power house of the Salem Electric Light Co., near the Naumkeag Mills, a brick building with large windows of wire-glass in metal frames, was a much better example of the kind of windows required in ordinary mercantile buildings. It came through the fire with only a small amount of blistered paint on the inside. The old [illegible] used as a storehouse by the Naumkeag Co. was a brick building with double metal doors, no windows, and a [illegible] roofing on wooden boards. The fire did not penetrate it.

The buildings which were saved clearly emphasize again the necessity for the protection to be taken against outside exposure, such as brick or concrete outside walls, noncombustible roofs and thoroughly protected openings.

"A Dry Land Mattress on the Mississippi;" the Sequel

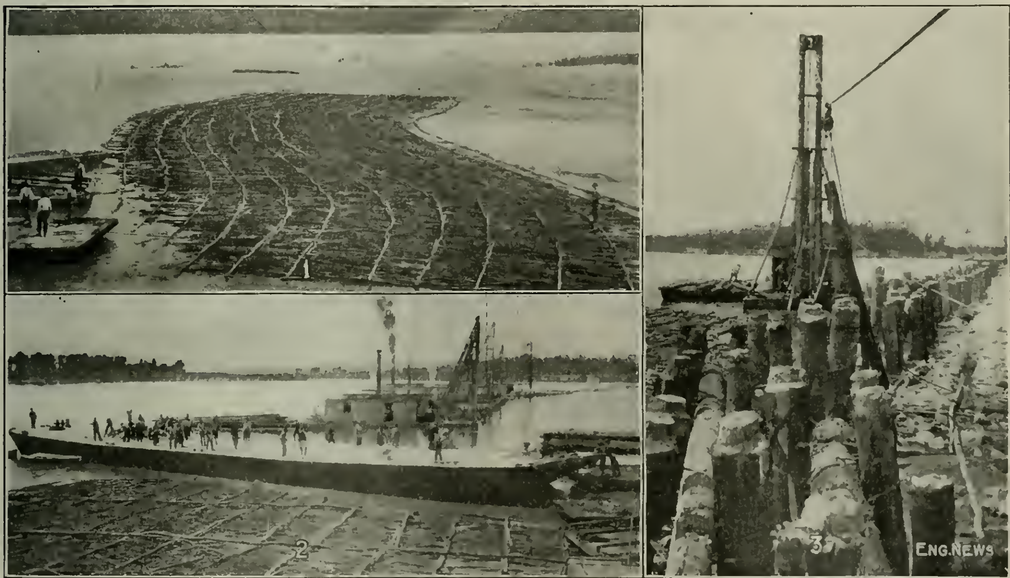
Sir—The quoted title heads a description, in ENGINEERING NEWS, June 4, 1914, p. 1243, of a mattress on the Mississippi, near Chester, Ill., constructed on the ground in order that the piledriving and mattress construction could be prosecuted simultaneously, when conditions were favorable.

The hoped for "rise," sufficient to float the plant over the bar, was forecasted by the Missouri River gage reports about the middle of June, and preparations were then made to begin the work at the earliest possible moment. Unfortunately the river did not reach a working stage until the latter part of the month, and valuable time was lost on account of Sundays and holidays; mattress construction and piledriving were begun on June 19, when soundings showed 2 ft. of water over the mattress end.

From the highest point of the mattress to end—[illegible] ft.—the slope was 1½%, consequently difficulty was experienced the first day in maneuvering the two piledrivers placed on the work. Additional drivers were placed as the river rose, until at the crest (June 22, "Belle of Memphis 'Forecast'" = 30.5 ft. St. Louis gage), six were in commission. Knowing that the rise would be of short duration and probably barely sufficient to float the drivers over the high point of the mattress, mooring piles were driven upstream and the building drivers dragged, to the extent of their engine capacity toward the bar top. Fig. 2 shows the far drivers back upward, working in 11½ ft. of water.

Great haste was necessary with the mattress construction on account of a second ridge or prong of the [illegible] that had to be crossed farther inward, Fig. 1. While it was not thought that the second ridge could be reached before the water began to fall, yet it would have been both economical and advantageous to build to the ridge, since scour usually takes place at the exposed end of a

hurdle mattress. In this endeavor aid was rendered, for a few days, by the river. The swift current in combination with the shoal water formed an undertow or suction under the plant, which caused a continuous scour of one to two feet in front of the unsunk mattress. However, as the water fell the scour decreased and failed to overcome the river fall and the rise of the bottom; the brush barge grounded, necessitating the launching and sinking of the mattress (Fig. 2). The direction of the weaving plant was reversed; the bows of the light-draft flats were shoved on the bar ridge and mattress building proceeded in the opposite direction until an overlap was made with the mattress previously sunk. By reversing the plant and direction of mattress construction, 300 ft. of mattress was added to the length. Fig. 2 shows the mattress thus constructed with preparations for weighting; the overlap and the hurdle end are in the foreground, the second ridge of the bar and river channel in the background.



FIGS. 1-3. LAYING A MATTRESS ON THE MISSISSIPPI IN VERY LOW WATER

Across the bar, piles were driven tip down. A greater cross-section of pile was thus obtained where the greatest breaking strength was needed.

At the top of the first ridge too shoal water for the piledrivers caused a small gap to be left in the hurdle, which was closed by cutting holes in the mattress and jetting in the piles. Fig. 3 shows a driver jetting piles 75 ft. distant.

During this "rise" 1000 ft. of hurdle and 1300 ft. of mattress was built, of which 300 ft. of mattress, in advance of the hurdle, is ready for piling on the next rise above the 20-ft. stage, St. Louis gage. That this "rise" will occur before the spring of 1915 is extremely doubtful.

F. Y. PARKER,
U. S. Assistant Engineer.

July 24, 1914, St. Louis, Mo.

On the Necessity of Heavier Pavement Foundations

Sir—I hope the article by Daniel B. Goodsell, on "Pavement Foundations for Heavy Traffic," in ENGINEERING NEWS of July 23, will call forth thorough discussion of the subject by municipal engineers in this country. It has long been my opinion that in laying pavement foundations, which to all intents and purposes should be useful for from 30 to 50 years, municipal engineers are extremely shortsighted in continuing to recommend 6 in. as the maximum thickness. This thickness is barely sufficient under favorable conditions for present traffic; and no account is taken of future growth in size of loads.

Everyone knows the pressure that is brought to bear on city officials to lower the first cost on all public improvements, and this must be credited as one of the extenuating circumstances which may have influenced the engineer against his better judgment. Four- and five-inch foundations, however, are altogether too common in the United States, and are entirely inadequate for even present needs.

All will agree that wheel loads have been increased enormously within the past five years with no apparent limit in sight for the future. A rich 6-in. portland cement concrete foundation may be strong enough to carry the heaviest load over ordinary sized depressions in the subgrade, without actually breaking down, but this is not all that is required of a pavement foundation.

The foundation must be rigid enough to maintain the wearing surface without appreciable deflection or vibration. For these purposes, mass as well as strength is essential just as in a reciprocating-engine foundation the mass necessary to absorb the vibrations determines the size, rather than the amount of load carried.

The increase in the speed of heavy loads due to motor trucks, has been as severe on old pavement foundations as the increase in the weight of the load itself. Every one has undoubtedly felt the violent jarring and shaking of the entire surface of a pavement during the passage of a loaded motor truck going 10 or 12 mi. per hr., especially if the pavement was slightly uneven. Recent experiments at the U. S. Bureau of Standards have shown that the effect of a slowly moving load of three tons on a block pavement laid on a 6-in. foundation could be detected as much as 110 ft. away. Any wearing surface is more or less injured by these constant deflections and vibrations.

Kansas City, a year ago, increased the thickness of foundation on business streets and trafficways from 6 to 8 in. of 1 : 3 : 6 portland cement concrete, and on residence streets from 5 to 6 in. No foundation is laid less than 6 in. thick, and several streets have been repaved with a new foundation 8 in. thick. Eight inches on residence streets and 10 or 12 on business streets should be required and will probably be specified as soon as the public will allow it.

In Kansas City, the entire cost of all paving, repairing or repaving is assessed directly against the abutting property, the owners of which consequently think they ought to have a deciding voice in what they have to pay for. There are a great many streets with a 6-in. natural-cement-concrete foundation, which the Engineering Department is recommending be replaced in nearly all cases of repaving. Why a foundation, which has stayed right where it is for 15 yr. should have to be replaced is often a mystery to the taxpayer.

It is my observation that a weak or insufficient foundation (and this does not necessarily mean a sunken or fractured base) is more of a detriment to asphalt and creosoted wood-block than it is to cement-grouted brick or stone-block. The last two named pavements are in a way partially self-supporting and apparently distribute loads over greater areas of base and subgrade.

Engineers should give the question of pavement foundations more careful and serious consideration; in which case, they will undoubtedly specify leaner mixtures and much thicker bases, which is in conformity with foreign practice mentioned in Mr. Goodell's article.

CLARK R. MANDIGO,
Assistant City Engineer.

Kansas City, Mo., July 27, 1914.

[illegible] of New Orleans, and built by the [illegible] Centrifugal Pump & Machine Co., Philadelphia. The engine was built by the Harrisburg Foundry & Machine Co., Harrisburg, Penn.

The City-Manager Plan of Municipal Government

By Paul E. Kressly*

The city manager is the latest innovation in the government of American municipalities, and strange to say, he is a direct indirect result of the Galveston hurricane. When fourteen years ago wind and wave conspired to wreck the Texas island city, the conditions created by the catastrophe demanded so much progressive and constructive work of the City Government that the old system of a board of aldermen and the usual string of independent elective officers broke down. A group of business men petitioned the state government to suspend the local government and replace it temporarily with a commission of five men. This was done, and the whole city was put under the control of these men, on a strictly business administration. The commission in a few days accomplished what a city council would have required months to do.

Des Moines, the Iowa capital, took up the idea, and improved upon it, and from that beginning the commission form of government has spread with surprising rapidity through the United States, and a peaceful revolution in four hundred cities has swept away the boards of aldermen, mayors and a host of minor officials and has set up new municipal governments on a plan so simple that the services of the "political boss" are not required to direct them.

The whole nation looks on with amazed enthusiasm, while the people in these towns not only get control over their government but keep it, election after election.

How and Why the Commission Plan Fails

The commission form of government has placed in the hands of the people an effective instrument of control; a governing organization which is continuously exposed to the full glare of public opinion, which really came from the voters, and which was sincerely anxious to obey them. While this form of government is a vast improvement over the form in general use up to seven or eight years ago, there is unquestionably room for still more improvement. In some of the cities it has proved very successful, while in others it has been a complete failure. This must not be regarded as a defect in the form of the government, but rather as due to the inefficiency of the members composing the commission. Take, for example, Wichita, Kan., where, as everywhere else, the commission plan was hailed five years ago as a "business plan" of city government which would settle all the difficulties under which the town had been laboring. Recently, the commission in this city has authorized the issue of $88,000 in five-year bonds to cover current deficiencies. After four years of the new rule, that does not look like good business. A little searching into the local situation reveals certain things which are directly or indirectly responsible for this condition.

One of the members of the Wichita commission is an ex-street laborer. Street work as a laborer is an honest calling, but does it give a man quite the preparation for managing one of the departments of a city as important as Wichita? There was doubtless excellent reason for electing him, for the labor people had an unquestionable right to select one of their men to represent them in a city's governing body. The man in question had a reputation for integrity and honesty, but even commission government has not made him a good business manager.

Here, then, is one trouble with the commission plan which the Wichita incident brought out in a graphic way: It is only by accident that you can secure five men who will be at the same time representatives of recognized divisions of the people and properly equipped for administrative service.

What, then, is the substantial and permanent contribution of commission government to the city problem? The one great thing it has done is to demonstrate beyond a shadow of a doubt the wisdom of giving over to a single elective governing body all the municipal powers. It has given the people a workable instrument, so far as general regulation is concerned, but it has failed to give the governing body the means with which to translate the general will of the people into detailed acts of government in the most effective way. A five-headed government carries with it the possibilities of friction, leads to inefficiency, which, in turn, leads to waste and even corruption. Furthermore, *municipal experts cannot be secured by popular election.*

The City Manager as Single Executive Officer

The city-manager plan does away with this five-headedness of municipal administration and substitutes a single head, not with advisory powers merely, but, subject to certain safeguards, with the powers of administrative "life and death," through actual control of appointments and removals.

The chief executive or city manager is not an elective officer, but is appointed by the council. He therefore does not divide responsibility with the council, but is subordinate to it. He need not be, at the time of his appointment, a resident of the city, but may be chosen from anywhere in the country. He is not chosen for a definite term, but holds office so long as he gives satisfaction to his superiors.

The controlled-executive plan filters everything through a group. It reduces the personal equation. Without loss of administrative unity, it abolishes one-man power. A single man may have his ups and downs, his freaks and fancies, his militant points and his passive ones, his natural bents and moods, his pet departments and projects. A board, or commission, or council, or parliament, has none of these things—to a group such excesses are relatively impossible. Even if all the members were cranks, their combined judgment would be reliable—they would neutralize each other.

This plan corresponds to the general manager under the board of directors in a business corporation. It gives the stability of the combined judgment of many men on matters of policy, but leaves execution to a single-headed controlled executive establishment.

For the highest efficiency we must put the chief administrative official, as well as subordinate officials of the same sort, on a professional basis. This means simply that we must leave his selection and his indefinite retention to some person or body that is in a position to examine his work closely and therefore judge of it intelligently, and that we must also take the matter out of politics, not by incessantly harping on the desirability of doing so, but by relieving him of all except purely administrative duties. That is not saying, you will notice,

*City Manager and City Engineer, Inglewood, Calif.

to mean anything, that "the people cannot be trusted to choose" the chief administrator. It is implying merely that they are not in a position to do so to advantage, and that if the official in question is given the veto and other policy-determining functions, neither the people nor anybody else can be expected, no matter how well they realize the advantage of experience in administrative work, to do anything but oust him as often as his opinions are not in conformity with those of the majority.

We are confronted with the question: From what profession or calling shall this important position of city manager be filled? My answer is, that the city manager should be a civil engineer, with municipal-engineering experience; who should also possess the additional qualifications of an economist, a financier, and have executive ability.

What other profession has men who are better qualified as municipal experts than the engineering profession? Are not the members of the engineering profession, in the course of their education, field work and research work, peculiarly qualified for executive duty developed by their training and experience? Engineering is perhaps as much a matter of common sense as of education, and the engineer, to succeed, must have both. Therefore, a capacity to get at the facts in any case, supplemented by good judgment, are predominating traits, characterizing this profession more prominently as essentials than is the case with any other profession or calling.

The City Manager of Inglewood, Calif.

The board of trustees of the city of Inglewood followed the very rational plan of appointing their city engineer, the writer, as city manager, he having served the city in the capacity of city engineer for two years. In the ordinance passed by the board creating this new position, practically all of the executive and administrative powers of the trustees are delegated to the city manager, and they have given him their personal assurance of their loyalty in anything he might undertake to perfect the organization and place the affairs of the city on a business basis.

The ordinance was passed on Mar. 2, and legally did not take effect until 30 days thereafter, but the board deemed it necessary that I be appointed and assume the duties of city manager at once. This procedure naturally caught me unprepared. However, I made the best of the situation, and began immediately to formulate plans.

My ideals as a basis upon which to erect the superstructure of my organization were efficiency and economy. In order that my administration should be successful, I was compelled to strictly adhere to my ideals and, in consequence thereof, I was obliged to make quite a few changes in the organization of several departments. On account of having been city engineer, I was familiar in a general way with the weaknesses of the various departments, and in order that they be corrected, I determined that the requisites of all employees should be efficiency, economy, loyalty and honesty, and that employees who possessed these qualifications should be retained, regardless of their political faith.

With the requisites thus set forth, a few dismissals were necessary, as this city, like many others, was not without political officeholders who held positions regardless of their qualifications or fitness.

I will not attempt to describe the reasons for the dismissals, but I wish to state that if any of my fellow-engineers ever receive the appointment of a city-managership, and they are obliged to dismiss employees, they need not be discouraged by threats and wild epithets being hurled at them by "political bosses," and their followers, since this is a natural procedure in the course of uncovering the "efficient" and "economical" work of their "pets." There is an erroneous impression grounded in the minds of so many municipal employees that they are not required to do as much work as for a private corporation; that they need not take any particular interest in the work; that working hours need not be observed; that they can take a leave of absence of a few hours every now and then, without consulting the head of the department, and at the same time be entitled to full wages; that they need not be courteous and accommodating to the public; that they can waste materials or supplies because the city pays for them. They labor under the pretext of the old political saying "to the victor belongs the spoils," and are therefore justly entitled to be given employment, and to do whatever they please, irrespective of the quality or quantity of the work performed, or of their value and worth to their employers, or interest taken in the business affairs of the city.

Specific Achievements at Inglewood

The following is a brief summary of some of the important movements undertaken and changes made in the various departments of Inglewood:

1. The removal of inefficient and incompetent men from the city service.
2. Requiring all employees to obtain an order, signed by the city manager, for the purchase of machinery, tools, supplies, materials, etc.
3. Accounting system installed and providing balance sheets of all accounts.
4. Limiting all city departments to a limited expenditure, and providing for an emergency fund, all within the actual revenues of the city.
5. Monthly detailed reports from each department.
6. Installation of unit-cost system, where practical in all departments.
7. Enlarging and defining the duties and powers of the Park Commission to exercise control and supervision of all parks and street tree planting, and of beautifying the street and avenue parkways by the formation of assessment districts to pay the costs and expenses thereof.
8. Arranged with electric light and telephone companies to have poles removed from streets and avenues into alleys.
9. An Ordinance prohibiting the trimming of street trees by property owners, and delegating these duties to the park commission and prohibiting the destruction of shade or ornamental trees, shrubs and flowers, and prescribing penalties therefor.
10. A Resolution providing for the removal of weeds from street parkways at the expense of the property owners.
11. Commission Appointed to Revise Building Ordinance.
12. Commission, composed of five members, one each from Grammar School Trustees, School Teachers, Parent-Teachers Association, Women's Club and City Manager, to arrange for the improvement and beautifying of school grounds.
13. Providing more convenient and enlarged quarters for the Public Library.
14. Establishing more stringent rules and regulations governing the care of buildings and equipment in the Fire Department.
15. Increased the efficiency of the Building, Plumbing and Electrical Inspection Department, and placed it on a revenue-producing basis.
16. Motorcycle officer ordered to strictly enforce ordinances pertaining to speeding on boulevards, and prohibiting heavy hauling on certain avenues.

17. Arrangement made with Fire Engineer to coöperate with City Marshal' department to receive calls for his department, thereby greatly increasing the efficiency of the Police Department.
18. Consolidating the City Engineer's and Street Superintendent's office, which heretofore were entirely separated; the City Engineer having had charge of all new improvements, while the Street Superintendent had charge of the maintenance and repairs.

FIG. 1. MOVING LARGE STEEL GRAIN TANKS AT CHICAGO

(Each tank is cut in two. The upper part is raised by the gallows frame while the lower part is moved out on rollers. Then the upper part is lowered and moved out in the same way.)

19. The removal of incompetent, inexperienced men from the service of the street department, and placing competent, experienced and able-bodied young men in their places, reducing the force to half the number.
20. Systematizing the work of the Street Repair and Maintenance Department, and establishing a unit-cost system for the various classes of street work.
21. Provision for a material supply yard adjacent to Railroad, and the housing of roller, graders and other implements.
22. Movement under way to require all public-utility corporations to take out permits for all street excavations, and requiring a deposit with street superintendent, an amount sufficient to cover the expense of replacing street surfaces to the original condition. Said work to be performed by the street superintendent.
23. The collection of rubbish and garbage.
24. Placing of receptacles for paper, rubbish, etc., along the principal streets of the city.
25. Effected the coöperation of the Police Department with the Health Department in enforcing quarantine ordinances and the strict enforcement of all ordinances pertaining to the health of the citizens and cleanliness of premises.
26. Compelling all employees to observe the following working hours; 8 a.m. to 12 m. and from 1 to 5 p.m.
27. Permission must be obtained from the heads of department before any employee is permitted to leave his regular duties.
28. Requiring an inventory of all office furniture, fixtures, supplies, machinery, tools, material, etc., to be submitted to the city manager.

The ordinance creating the city managership in Inglewood, defines his duties and powers, and gives him authority to exercise control over all departments, but expressly excepts the legal department from the operation of the ordinance. In my opinion, based upon past experiences, this is a serious defect. The city attorney should be under the control of the manager, because there is not a single department in any city which causes more delays in public-improvement proceedings than the legal department. These delays are a handicap to the engineering department, oftentimes proving to be an additional expense, which could have been avoided if the city manager exercised control of that department.

Moving Large Steel Grain Tanks

The moving of large steel storage tanks a distance of about five miles is interesting work in connection with the removal of the Albert Dickinson Co., seed merchants, of Chicago, to a new plant at Washtenaw Ave. and 35th St. near the Drainage Canal. The old plant was at Taylor St. and the Chicago River, but the site is being cleared for the new terminal work of the Pennsylvania Lines. The equipment included 22 steel storage tanks 60 and 40 ft. high and 30 and 40 ft. in diameter, weighing 40 to 50 tons each. As these were in good condition it was desired to move them to the new plant. The tanks are covered with conical tops supported on light radial trusses.

The method adopted was as follows: A timber gallows frame was built, large enough to straddle a 60-ft. tank, and having two sets of hoisting tackle on the crossbeam. This was set up over a tank, and the hoisting hooks attached to two sling plates bolted to the top of the tank, as shown in Fig. 1. The rivets of the middle circular seam were then cut out by hand, and the upper half of the tank was lifted by the tackle. Then the lower half was raised by jacks sufficiently to allow of placing under it four heavy timbers, with blocking and wedges to support it at various points. Under this supporting frame were

FIG. 2. THREE SECTIONS OF TANKS ON A SCOW, READY FOR UNLOADING AT THE NEW SITE

two lines of timbers with planking, forming roller runways for the wooden rollers used in moving buildings.

The lower section of the tank was then hauled out by a hoisting engine, the block of the hauling rope being hooked to a bridle attached to the two side timbers of the supporting frame. A similar frame was then built and the upper section of the tank lowered upon it. These frames remained under the tanks throughout their removal. Each section of tank was held in shape by an interior frame of four timbers, with blocking between these

and the tank shell, there were also interior ties of wire cable attached to threaded rods which passed through rivet holes and were secured by nuts.

A double-track roller runway was built through the yard to the river bank, and the tank sections hauled on this and onto a large deck scow, the scow holding three sections, as shown in Fig. 2. The scow was then towed down the river and the Drainage Canal to a point near the new plant. A roller runway, supported on piers of blocking, was extended from the deck to the bank, and the tanks were hauled off by a horse winch. The final disposition has not been decided. They may be erected on a site adjacent to the canal, or they may be moved to the site occupied by the rest of the plant. In the latter case, they will have to be raised and transferred across two railway embankments and a small canal.

This work was undertaken by the John Eichleay, Jr., Co., of Pittsburgh, Penn., which makes a specialty of moving houses and other structures. They state that the tanks could have been moved without cutting them apart but for the large number of electric wires and cables strung along the drainage canal. The river trip was somewhat slow, as there were 17 bridges to pass (including a four-track bascule bridge with each section operated independently). The Western Ave. swing bridge over the canal has no operating machinery, and had to be operated by the tugs, which cast loose the scow and hitched their tow lines to chains hanging from the ends of the adjoining bridge.

A Hydraulic Sand-Mining Plant

By R. A. Boehringer*

Between Lewistown, Penn., on the east and Huntingdon on the west, the Juniata River cuts through sandstone ridges, which run approximately north and south. These ridges, between the Blue Mountains on the east and the Allegheny Mountains on the west, consist mainly of silicon dioxide, which finds extensive application in the manufacture of glass of all kinds, fine plaster, crucible steel, fire brick, by railways for use on slippery rails, and in the purification and filtration of chemicals and water.

The ridges occur in the form of sand rock, which is both quarried and mined by a number of different companies for the manufacture of sand. The total output of commercial sand from the companies in this locality is about 1500 tons daily. The largest of these companies is the Pennsylvania Glass Sand Co., and this concern has installed a hydraulic sand plant near Vineyard, Penn., which is unique in this part of the country.

The buildings of the new works are located at the foot of a steep hill, with the quarry about 100 ft. vertically above. Across a small ravine above the quarry a masonry and concrete dam has been built, forming a reservoir of 500,000 gal. capacity, which distributes water to the

*Division Engineer, Water Supply Commission of Pennsylvania, Harrisburg, Penn.

General View of Hydraulic Sand-Mining Plant, Vineyard, Penn.

[illegible] the Juniata River [illegible]

monitor, the quarry, the sand-washing machines and the boilers.

In the operation of the quarry, the general method of procedure at first was to use the hydraulic process when there was sufficient soft material encountered, and to blast the rock when the stream from the monitor was unable to supply sand to the washing machines. In this way, it was found that about 50% of the average daily output of 125 tons of sand could be produced hydraulically. Later experience has shown that except where it is necessary to loosen ledges of the harder rock with dynamite, blasting is no longer required, and it has been superseded by the hydraulic method.

A 6-in. pipe is laid to the middle of the quarry floor, to which a 6 to 7/8-in. monitor is attached. The monitor is detachable, so that it will not be injured when blasting. The monitor plays upon the face and floor of the quarry, loosening and bringing large blocks of rock to the floor, and washing the loose sand and small stones into the opening of a trough at the lower end of the quarry, toward which the floor slopes.

On account of the trouble in fastening and unfastening the monitor, a 2½-in. fire hose with a ¾-in. nozzle is now used most of the time, and is fastened on taps on the pipe line which encircles the quarry. With one man at the hose and one to keep the troughs clear, they can deliver to the reduction house from 25 to 40 tons of sand per hour. An exploration drift shows that the material becomes better and is more easily mined hydraulically as the hillside is washed back farther.

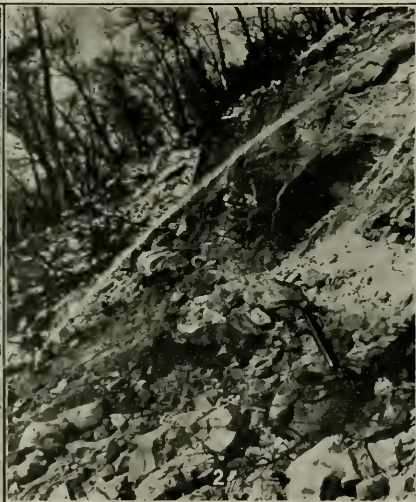
The sand and water are carried in a 10x12-in. flume 50 ft. to the reduction house, where it enters a revolving screen. This is a double screen, with a ½-in. mesh on the inside and a 12-in. mesh of No. 20 wire on the outside. The function of the inside screen is to receive the raw material, screen out the sticks and twigs which come from the thick forest cover of the quarry, and to take out the small stones, which are wasted. This waste, however, amounts to very little.

From the revolving screen the sand is shot through a short trough direct to the washing machines. These machines consist of an inclined box with four alternating screws and troughs. The sand comes from the revolving screen into one end of the washing machine. A screw, working in the machine, carries the wet sand to the top of the inclined box, where a jet of water plays on the sand, washing it down a trough, beside and parallel to the screw, to the bottom of the box. Here a second screw carries the wet sand to the top of the box, where a second jet washes the sand down a second trough to the bottom of the box. This operation is repeated in the third screw and trough, after which a fourth screw carries the clean sand to the top of the inclined washer, where the sand is dropped off on a belt conveyor and carried to huge piles, where the water is allowed to drain off before shipping the sand.

The large blocks of rock in the quarry are blasted and broken up, loaded into dump cars on narrow-gage tracks, and pushed by the quarrymen to a rock crusher in the reduction house. Leaving the rock crusher, the stone is further ground up in a revolving mill, from which it passes into a revolving screen. From the screen, stones which escaped crushing are returned to the grinding mill, while the sand drops into washers similar to those which clean that brought to the reduction house by the hydraulic process.

After the crusher sand leaves the washers, it is carried by a belt conveyor, working on V-shaped rollers, to the drain and dry building, where it is dumped into great piles, where the water is permitted to drain off. When the sand is dropped from the conveyors, it contains from 25 to 28% of water; after standing 48 hours, it still contains about 12%.

The drain and dry house has a storage capacity of 3600 to 3800 tons of sand. The storage space occupies the middle and one side of the building, while the other side is occupied by the dryers. The latter consist of a brick prism filled with steam pipes. The top is open to



Figs. 1 and 2. Typical Parts of Quarry Face

Fig. 3. Flume to Plant

[illegible] the wet sand, while the bottom is V shaped, with a [illegible] traversing the length of the dryer at the bottom of the open V.

Between the storage space and the dryer is a concrete wall on which a traveling bucket-conveyor is mounted to take the sand from the drain piles to the dryers. The buckets are loaded by hand, and with the exception of the work done in the quarry and in placing the finished sand in box cars, this is the only place where the sand is handled. In the drain and dry building, however, provision has been made for the future installation of a traveling crane operating a grab bucket, which will be used in moving the wet sand from the piles into the dryers.

From the dryers the sand will be carried by a belt and a bucket conveyor to a 20-mesh screen near the top of a 57-ft. tower, where the pebbles are separated from the fine sand. From this screen the finished product will be carried by a short bucket conveyor to large bins in the top of the tower, from which it can be shot straight down into cars on a side track below.

NEWS NOTES

A Covered Wooden Bridge Burned on the Schuylkill & Lehigh Division of the Philadelphia & Reading Ry., near Kempton, on July 30.

Two Houses Collapsed. Undermining from an adjoining cellar excavation caused a house, in Toronto, Ont., to collapse, on July 23.

A house in Evansville, Ind., collapsed, on July 28, while being wrecked.

A Derrick Car Turned Over on the western viaduct approach of the Hell Gate Bridge of the New York Connecting Railway, at E. 142d St., the Bronx, on Aug. 1, killing one man. The derrick was used for erecting steelwork. Its capacity was [illegible] tons.

The Supports of an Old Timber Bridge Failed at Branford, Conn., on July [illegible] under the weight of a cartload of [illegible]. Although the bridge settled, the flooring was firm enough to permit the cart to proceed safely to the road beyond. A number of boys sitting on the rail, fishing, were [illegible].

A Timber Bridge Collapsed under the weight of a wagon-load of [illegible], at [illegible], on July 21, injuring the driver. The length of the bridge was about 17 ft.

On July [illegible], near [illegible], Kan., a county bridge over the [illegible] River fell under the weight of a milk wagon. The bridge was about [illegible] ft. long.

A Disastrous Wreck Occurred at Tipton Ford, Mo., on [illegible], when a Kansas City Southern Ry. passenger train and a [illegible] motor car met in a butting collision, [illegible] [illegible]. Press dispatches state that the car had orders to wait at a point [illegible] of Tipton Ford, but the orders were [illegible]. [illegible]

Another Timber Pier Fire [illegible]

[illegible] ons were injured. Included in the fire damage is the damage to stored freight, which was in the warehouse. The Pacific Alaska Navigation Company's steamship "Admiral Farragut" was lying alongside the Grand Trunk pier waiting to sail for San Francisco when the fire started. The liner, which had all her cargo and most of her baggage aboard, cast loose and escaped damage. The fire started near the river end of the pier and spread toward the shore. As is common in pier fires it was most difficult to fight.

From Gen. H. M. Chittenden, Port Commissioner of Seattle, we have had the following word:

"The present slips are altogether too narrow and business has been seriously handicapped on that account. Although it is rumored that the Grand Trunk Pacific is to rebuild its pier in concrete, what should be done is that the port district should take over the Grand Trunk and the Coleman piers and rebuild as one pier, thus doing away with the narrow intermediate slip. It is quite possible, however, that the city will hesitate on account of the heavy cost. The new port district wharves are of timber, sprinkler protected, with the warehouses and other structures of concrete. With proper fire measures and reasonable precautions such structures need not be so dangerous as is commonly supposed. Whether in a particular case the fire risk justifies the heavy extra cost of concrete work must be decided by the circumstances. Certainly no hard and fast rule is possible, and there is no justification of unnecessary financial sacrifice simply to meet more effectually one feature of construction and use."

The Pathfinder Reservoir of the North Platte Project (Nebraska-Wyoming) of the United States Reclamation Service was filled for the first time in June, 1914. On June 27 the storage amounted to about 1,085,000 acre-feet and water to a depth of 0.9 ft. was running over the spillway.

Water Deferrization and Demanganation at Lowell, Mass., in accordance with the scheme outlined in our issue of July 9, 1914 (p. 107), has been authorized by the city council. An appropriation of $190,000 for the work has been made. Robert J. Thomas is Superintendent of Water-Works at Lowell.

The "Adamson Bill" amending the "General Dam Act" of Congress (as approved June 21, 1906, and amended June 23, 1910) passed the House, Aug. 1. It was read twice in the Senate, Aug. 5, and referred to the Committee on Commerce. This is the administration measure to facilitate and regulate the development of water power on navigable streams.

The Snoqualmie Tunnel of the Chicago, Milwaukee & St. Paul Ry. through the Cascade Mountains was holed through on Aug. 1. The tunnel ranks among the very long railway tunnels in the United States, having a total length of about 12,000 ft. It reduces the summit level of the line crossing the range 413 ft., saving also 4 miles in distance, while the line which will be abandoned was subject to heavy snowslides.

Freight Transportation on an Inland Waterway Route is being developed by the Chicago, St. Louis & Gulf Transportation Co. on the Illinois & Michigan Canal [illegible] freight from Chicago and vicinity to points on the Illinois and Mississippi Rivers. In order to bring freight to the waterway its promoters have made surveys for a terminal railway from La Salle, Ill., to Oglesby, connecting a number of large cement plants and manufacturing establishments. An interurban railway from La Salle to [illegible], Ill., is also proposed.

Commercial Opening of Panama Canal. The Secretary of War has announced that the Panama Canal will be opened to traffic on Saturday, Aug. 15, to vessels drawing not to exceed 30 ft. of water. This stipulation is made because of the conditions at Cucaracha slide, which, although greatly improved, would not admit of the passage of vessels with absolute safety drawing a greater depth of water. This restriction, however, probably does not affect any vessel now using the Panama route regularly, either in the Atlantic or Pacific.—"The Canal Record."

Use of Streets for Construction Purposes. The blocking of a street adjacent to a building under construction by the storage of construction materials, etc., was prohibited by ordinance at Houston, Tex., on July [illegible]. It is now required that the contractor secure from the city engineer a permit for the use of a portion of the street. [illegible] the walk can be used on only one adjoining street, to be designated by the city engineer. As soon as the building material can be placed inside the new structure, the city engineer has the power to revoke the permit. The penalty for violation is a fine of not less than [illegible] per day, [illegible] [illegible] will forfeit the right to obtain permits thereafter.

A Railway Tunnel five miles in length under the Jura Mountain range in Northern Switzerland was holed through on July 10. The work of construction is described in "The Engineer," London, of July 24. The tunnel is located about two miles south of Basel, on the German frontier of Switzerland. The old line from Basel south to Olten, which also has a tunnel about 1½ mi. long, has long grades of 2.6% and a much higher summit level than the new line built to pass through the new 5-mi. tunnel. The new tunnel is built for double track and is lined throughout, concrete having been used in most places. Work upon the tunnel was begun Feb. 1, 1912, and the contract date for completion was Jan. 13, 1915. The contract price was £792,709, with a bonus of $60 a day for each day's advance in the completion of the work.

Applications for the City Managership of Bristol, Va., are wanted. The facts in the case are thus stated in a letter to this journal, written by John H. Gose, City Clerk.

The city of Bristol, Va., is considering the employment of a competent man, with experience in engineering, to act under the supervision of the City Council as Executive Manager for the city, to perform the duties of street and water commissioner, have charge of all construction and repair work, the employment of all labor in these departments, and to purchase all supplies and material under the supervision of the Purchasing Committee of the Council. Salary per month will likely be fixed at $125 or upward. Applicants will please state age, ability to handle labor and an outline of the various positions held and the length of time in each, as far as practicable, and furnish such recommendations as they may desire. Also state salary expected.

Applications for the position should be addressed to John H. Gose, City Clerk, Bristol, Va.

Statistics of the World's Merchant Marine, made public by the Department of Commerce on Aug. 8, are of special interest in view of the probability that the European war will compel the United States to embark largely in ocean shipping. The merchant ships of the world aggregate 47,000,000 gross tons, of which 40% belong to Great Britain, 11% to the United States, 11% to Germany, 5% each to Norway and France, 3% each to Holland, Italy and Japan. While the United States is second only to Great Britain in volume of shipping, the great bulk of its ships are engaged in the lake and coasting trade, the total so engaged being 9,800,000 tons, while our total shipping in foreign trade is only 1,027,000 tons. It is of interest to note further that while the total capacity of the world's merchant shipping has doubled in the past twenty years, the number of vessels employed is about the same as twenty years ago, indicating that the average tonnage of merchant vessels has doubled in that time.

A New Steel Bridge with Concrete Floor Was Moved late position recently, on the Lehigh Valley R. R. at Wende, N. Y. (Erie County), replacing a lighter structure. The work was quickly performed. F. E. Schall, Bridge Engineer of the railroad, provides the following data:

The bridge is a double-track deck plate-girder bridge 98 ft. long, consisting of four girders, reinforced-concrete floor, waterproofing, brick waterproofing protection, stone ballast and track. The reinforced-concrete floor is supported upon I-beam cross girders resting on top of the plate girders, each track separate.

The new bridge was erected to the north of the old bridge, all complete, including the steelwork, concrete floor, ballast and track. After the proper seasoning of the concrete, the girders between the two tracks were blocked to form a unit laterally, for movement.

The tracks were cut and the old bridge rolled southward on timber bents; then the new bridge was rolled into position, both tracks simultaneously.

The weight of the steelwork including reinforcement steel is 521,000 lb., the weight of the concrete, waterproofing and protection, stone ballast and track is about 850,000 lb., a total of 1,371,000 lb. or 685½ net tons.

The Largest Diesel Oil Engine yet built in America is said to be one just shipped by the Lyons Atlas Co. of Indianapolis. It is rated at 600 b.hp. with an overload capacity of 15% with an 890-b.hp. maximum. It is a vertical four-stroke cycle engine with cylinders 21x30 in. and has been shipped to the Hawaiian Commercial & Sugar Co. to supersede a steam plant for pumping water for irrigation. The engine is direct-connected to a two-stage turbine pump capable of delivering 15,000,000 gal. of water per day under 200-ft. head. The builders have furnished the following statement as to the conditions under which the engine was built and the tests to which it was subjected:

"The purchaser required that the engine should operate continuously 710 hours out of each 720 hours per month at rated load, using the ordinary 14% to 18% asphaltum-base California fuel oil, similar to that used in the purchaser's steam plant, and which is the only grade available on the Islands.

"The test was conducted by the chief engineer of the Hawaiian Commercial & Sugar Co., and the engine was given a preliminary, continuous run of 48 hours with eastern paraffin-base fuel after which all parts connected with the combustion chambers were inspected in order to determine a basis for comparison between the effect of the two fuels. It was then subjected to a 144-hour continuous run at full load with fuel shipped by the purchaser from California to the manufacturer's works. At the completion of this run the combustion chambers were again examined, and as there was no evidence of deposit on the heads, valves or pistons, the engine was accepted and is now en route to the Islands, to be erected by their own engineers without any assistance from the manufacturer."

A Report to the Dayton Flood Prevention Committee, of Dayton, Ohio, has been published. The report was made by a Special Board of Consulting Engineers of eight members, and approves the plans for the proposed Miami Conservancy District made by the Morgan Engineering Co., of Memphis, Tenn., and Dayton, Ohio. The original intention was to submit the report to the Conservancy Court created to pass on the petition for the establishment of the proposed district, but litigation having postponed the hearing indefinitely, it was decided to publish the report without further delay.

The eight members of the Special Board of Consulting Engineers were: Gen. O. H. Ernst, Washington, D. C.; J. A. Ockerson, St. Louis, Mo.; Gen. H. M. Chittenden, Seattle, Wash.; T. W. Jaycox, Denver, Colo.; J. H. Fuertes, New York City; W. A. O'Brien, Cape Girardeau, Mo.; Charles H. Miller, Little Rock, Ark.; and Morris Knowles, Pittsburgh, Penn. The report is 20 printed pages in length. It reviews briefly flood conditions in the Great Miami Valley in general and the 1913 flood in particular, and considers possible remedial measures. The Board concluded that protection by channel improvement for the entire river would cost about $100,000,000 against $18,000,000-$20,000,000 for detention basins and limited channel improvements, and that the maintenance cost would be correspondingly heavy and light, respectively. The final opinion of the board was as follows:

(1) That floods as great as that of 1913, and even greater, are liable to occur at any time, and preventive measures should be carried out which will control floods about 20% greater than that of 1913.

(2) That permanent flood protection for the Miami Valley by means of channel enlargement alone is impracticable.

(3) That detention basins, supplemented by limited channel improvement, do offer a satisfactory solution of the problem.

(4) That the success of such plan for flood control requires that the flooded area of the Miami Valley above the Whitewater River be considered as a unit.

(5) That the works of the type suggested, properly designed, located, and constructed, will not only provide satisfactory and economical protection from floods, but they will be so massive and substantial as to fully justify confidence in their integrity, and satisfy every reasonable question of stability.

It may be added that the plans here passed upon were made under the immediate direction of Arthur E. Morgan, of the Morgan Engineering Co., with the advice of the following consulting board: John W. Alvord, of Chicago; Prof. Daniel W. Mead, of Madison, Wis., and Chicago, and Prof. S. M. Woodward, of Iowa City, Iowa.

PERSONALS

Mr. R. A. Baldwin has been appointed Engineer of Maintenance-of-way of the Ontario grand division of the Canadian Northern Ry., Eastern lines, with headquarters at Toronto, Ont.

Mr. Jesse K. Giesey, Assoc. M. Am. Soc. C. E., Assistant Engineer of Hering & Gregory, Consulting Engineers, New York City, has resigned to take charge of sewer work in York, Penn.

Mr. E. C. Deal has been appointed Vice-President and Chief Engineer of the Carolina & Yadkin River Ry., with headquarters at Greensboro, N. C., succeeding Mr. J. P. Clark, resigned.

Mr. William A. Hansell, Jr., M. Am. Soc. C. E., formerly with the city engineering department of Atlanta, Ga., has been elected Superintendent of Public Works of Fulton County, Ga.

Mr. J. D. Evans, formerly Chief Engineer of the Central Ontario Ry., at Trenton, Ont., has been appointed Division Engineer of the Ottawa division of the Canadian Northern Ry., with headquarters at Ottawa, Ont.

Mr. G. F. Stickney, M. Am. Soc. C. E., Supervising Engineer

of the New York State Barge Canal, Albany, N. Y., has been granted three months' leave of absence to go to Pittsburgh, Penn., to make the preliminary estimates and plans for the Ohio & Lake Erie Canal. The work will take about three months.

Mr Arthur F Ballou has resigned as Superintendent of the Providence, R. I., Water-Works Department, to become connected with the National Board of Fire Underwriters. He is succeeded as Superintendent by Mr Carleton Scott, Assistant Engineer, City Engineer's Office of Providence.

Mr William J Hazeltine has been appointed City Engineer of Mansfield, Ohio, succeeding Mr Emmet Merkel, resigned. Mr Hazeltine is an engineering graduate of the Ohio Northern University, class of 1911, and has had some street and road experience in New York and New Jersey.

Mr W C Schade has been appointed General Manager of the Phoenix Iron Works Co., Meadville, Penn., effective Aug 15. Mr Schade resigned as President of the Cherry Tree Iron Co., Cherry Tree, Penn., last February, but his resignation was not accepted owing to the inability of the company to find a suitable successor.

Mr Charles O Tappen has resigned as Chief Engineer of the Northern Power Co and the Hannawa Falls Water Power Co., Potsdam, N. Y., and has opened an office as Consulting and Constructing Engineer, 2 Rector St., New York City, specializing in hydro-electric power, transmission, public utilities engineering, valuation and appraisal work.

General Joseph Joffre, Commander-in-Chief of the French Army in the present European War, is a notable civil engineer. He is a graduate of the École Polytechnique, Paris, France. He saw much of his early service with the engineer corps and has had charge of railway construction in West Africa and harbor work in Madagascar.

Mr Othmar Hermann Ammann, M Am Soc C E, Assistant Chief Engineer of the New York Connecting R.R., which is building the Hell Gate steel arch bridge, is among the foreign army reserve officers who have been called back to their native countries. Mr Ammann is a reserve officer in the Swiss Army and has returned to Switzerland to offer his services.

Lord Horatio Herbert Kitchener, the new head of the English War Office, is an engineer by education and experience as well as a soldier. Lord Kitchener is a graduate of the Royal Military Academy at Woolwich, and entered the Royal Engineers in 1871. Between 1874 to 1882 he had charge of extensive survey work in Palestine and the island of Cyprus. For several years he was head of the Royal Engineers.

Mr A J Hills, former Superintendent of the Canadian Northern Ry., at Toronto, Ont., has been promoted to be General Superintendent of the Ontario grand division of the Canadian Northern Ry., Eastern lines, in charge of operation, maintenance-of-way and motive power, with headquarters at Toronto, Ont. Mr Hills is an engineering graduate of the University of Toronto, and for several years following his graduation in [illegible] he was with the construction department of the Canadian Northern Ry. at Winnipeg, Man.

Mr Frederic A Delano, M Am Soc C E, former President of the Wabash R.R., now President of the Chicago, Indianapolis & Louisville Ry., has been appointed a member of the Federal Reserve Board. Mr Delano is also a member of the Government Commission on Industrial Relations, to which he was appointed by President Taft. He takes the place on the Federal Reserve Board made vacant by the withdrawal of Mr Thomas D Jones. Mr Delano is a well known writer on railway and transportation problems, and is a civil and mechanical engineer of many years' experience. He was born in Hong Kong, China, in 1863, but spent most of his boyhood years at Newburgh, N. Y., where he prepared for Harvard College. Mr Delano graduated at Harvard in 1885 and the following summer joined a survey party of the Chicago, Burlington & Quincy R.R. in Colorado. In the fall of that year he became a machinist apprentice at the shops of the railway at Aurora, Ill. Two years later he was placed in charge of the bureau of steel rail inspection tests and records. After a year as Assistant to the Second Vice-President, he was appointed Superintendent of Freight Terminals at Chicago, Ill., where he remained for nine years. Later he was Superintendent of Motive Power and, from 1901 to 1905, was General Manager. For a few weeks in 1905 he was Consulting Engineer to the United States War Department and the Philippine Commission, after which he returned to the railway service as Vice-President of the Wabash R.R. He was elected President in 1911; later he was Receiver. He was elected President of the Chicago, Indianapolis & Louisville Ry. in the latter part of 1913.

Regarding his recent nomination to the Federal Reserve Board, Mr Delano is quoted by a New York "Times" correspondent as follows:

If President Wilson should nominate me, and my nomination were confirmed by the Senate without quibbling, I should feel it my duty to accept. I neither want the place nor have I sought it, and I certainly could not take it if my record were not such as to warrant my confirmation without a personal examination. But if I am appointed without any solicitation on my part, I shall accept it, as I believe it would be my duty to do so.

OBITUARY

William Barstow Strong, former President of the Atchison, Topeka & Santa Fé Ry., died Aug. 3. He was born in Vermont in 1837.

ENGINEERING SOCIETIES

COMING MEETINGS

AMERICAN ASSOCIATION OF RAILROAD SUPERINTENDENTS.
Aug. 20-21. Annual meeting in New York City. Secy., E. H. Harman, Room 101, Union Station, St. Louis, Mo.

AMERICAN PEAT SOCIETY.
Aug. 20-22. Annual meeting at Duluth, Minn. Secy., Julius Bordollo, 17 Battery Place, New York City.

AMERICAN BOILER MANUFACTURERS' ASSOCIATION.
Sept. 1-4. Annual convention in New York City. Secy., J. D. Farasey, E. 37th St. and Erie Ry., Cleveland, Ohio.

AMERICAN MINE SAFETY ASSOCIATION.
Sept. 7-10. Annual meeting in New York City. Secy., H. M. Wilson, Bureau of Mines, Pittsburgh, Penn.

AMERICAN FOUNDRYMEN'S ASSOCIATION.
Sept. 7-11. Annual meeting at Chicago, Ill. Secy., A. O. Backert, Cleveland, Ohio.

NATIONAL PAVING BRICK MANUFACTURERS' ASSOCIATION.
Sept. 9-11. Annual convention at Buffalo, N. Y. Secy., Will P. Blair, 832 B. of L. E. Building, Cleveland, Ohio.

NATIONAL ASSOCIATION OF PORT AUTHORITIES.
Sept. 8-10. Annual convention in Baltimore, Md. Secy., Wm. Joshua Barney, 29 Broadway, New York City.

ROADMASTERS AND MAINTENANCE OF WAY ASSOCIATION OF AMERICA.
Sept. 8-11. Annual meeting at Chicago, Ill. Secy., L. C. Ryan, Sterling, Ill.

MASTER CAR AND LOCOMOTIVE PAINTERS' ASSOCIATION.
Sept. 8-11. Annual convention in Nashville, Tenn. Secy., A. P. Dane, Reading, Mass.

NEW ENGLAND WATER-WORKS ASSOCIATION.
Sept. 9-11. Annual convention in Boston, Mass. Secy., Willard Kent, Narragansett Pier, R. I.

INTERNATIONAL ASSOCIATION OF MUNICIPAL ELECTRICIANS.
Sept. 15-18. Convention in Atlantic City, N. J. Secy., Clayton W. Pike, Electrical Bureau, Philadelphia, Penn.

ILLUMINATING ENGINEERING SOCIETY.
Sept. 21-24. Annual convention in Cleveland, Ohio. Secy., Joseph D. Israel, 29 W. 39th St., New York City.

RAILWAY SIGNAL ASSOCIATION.
Sept. 22-24. Annual convention in Bluff Point, N. Y. Secy., C. C. Rosenberg, Times Building, Bethlehem, Penn.

American Society of Agricultural Engineers—The annual meeting of the Society will be held in Madison, Wis., Dec. 28-30. The preliminary program has just been issued. The Secretary is F. M. White, Madison, Wis.

American Road Congress—The Fourth American Road Congress will be held at Atlanta during the week of Nov. 9. State Highway Engineer Fletcher, of California, has been elected president and will preside at the opening session. One of the subjects for discussion is "Systematic Road Management," including the organization of working forces and the methods of reporting and recording work. This subject will be presented by Hon. Chas. J. Bennett, State Highway Commissioner of Connecticut. State Highway Engineer Keller, of Alabama, will deal with the subject of "Engineering Supervision." Among the various phases of construction and maintenance of all types of roads, the construction known as the sand-oil method, involving the use of a mixture of asphaltic oil and sand, will be thoroughly discussed. This type of road is in use in the Cape Cod region of Massachusetts and in the vicinity of Palm Beach, Fla. Fairfax Harrison, president of the Southern Ry., is scheduled to speak on the relation between the railroads and the wagon roads. The present headquarters of the Congress is in the offices of the American Highway Association, Colorado Building, Washington, D. C.

Engineering News

VOLUME 72 AUGUST 20, 1914 NUMBER 8

Great Northern Ry. Improvements at Seattle, Wash.

By E. E. Adams*

SYNOPSIS—The Great Northern Ry. line through the northern part of Seattle has been relocated and elevated and all street grade crossings eliminated. A new double-track steel bridge crosses Salmon Bay, and has a 200-ft. bascule span for the channel. The girder spans crossing streets have a concrete-slab deck with ballasted tracks. One of the channel piers was built in a timber crib sunk in place, and having the lower part of the concrete deposited by a tremie.

In connection with the improvement of the Great Northern Ry. between Everett and Seattle, Wash., the line within the city is being improved.† This work consists in replacing the old single-track line by a new double-track location at higher elevation, and building a new bridge over the Salmon Bay Waterway, which forms the west entrance to the U. S. Government canal connecting Puget Sound with Lake Washington. It was provided that : (1) all street crossings should be under or over the new grade; (2) the compensated grade should not exceed 0.1%, with curvature as light as possible; (3) the roadbed should be wide enough for four tracks. The location is shown in Fig. 2.

The city council granted the franchise in June, 1912, and a permit for the crossing of the waterway was secured from the U. S. Government. Construction was undertaken at once, and the work comprised three parts: (1) the new line from Metum (the station at the north city limits) to Interbay, at the head of the company's freight yards; (2) filling the trestles extending two miles from Interbay along the water front; (3) the bridge over Salmon Bay Waterway. The work was under the direction of the engineering department of the Great Northern Ry.: R. Budd, Chief Engineer (now Assistant to the President); Alex. Stewart, Assistant Chief Engineer; O. S. Bowen, Resident Engineer (now principal Assistant Engineer). The writer was Assistant Engineer during construction.

Fig. 1. New Bridge with 200-Ft. Double-Track Bascule Span over the Salmon Bay Waterway at Seattle, Wash.; Great Northern Ry.

(The girder spans at the ends of the bridge have a reinforced-concrete slab deck for ballasted track. The four girder spans nearest the channel have open-floor construction.)

Building the New Line

The work on the north section, from Metum to Salmon Bay, involved rebuilding 2½ miles of track on a new grade of 0.1%. The old track followed a sinuous alignment along the bottom of the high bluffs, and the relocation crossed and recrossed above it at heights up to 23 ft. As the old track was under continuous train movement, it was decided to divert traffic to a temporary track on a pile trestle, one mile long, along the shore; this was parallel to the new track location and along the line of the toe of slope of the new four-track embankment, Fig. 2.

The trestle served to carry traffic during the construction period, and served also as a temporary bulkhead to

†The railway terminals of Seattle were described and illustrated in "Engineering News," Aug. 8, 1912.—Ed.

*Assistant Engineer, Great Northern Ry., Seattle, Wash.

protect the earth embankment from being washed away. The temporary planking of this bulkhead trestle was later reinforced by about 40,000 cu.yd. of riprap rock. The location and grade of the trestle will be maintained and in future the tracks will serve docks and warehouses along this section of the waterfront. About 310,000 cu. yd. of hardpan and blue clay were moved by a steam shovel, 4-yd. side-dump cars, and small locomotives.

The south section of the line, from Salmon Bay to Interbay, was located through a sparsely settled section of the city, and followed the general contour of a broad flat side hill, the tracks being from 25 to 90 ft. below the surface. All of the streets which were not vacated and those which provide the best channels for street traffic will be carried over the tracks on bridges. In order to eliminate overhead bridges at street crossings not vacated, the railway purchased an additional strip of property and deeded to the city a street or boulevard 100 ft. wide and a mile long, near the top of the slope of the cut and parallel to the tracks. This is shown in Fig. 2 (Gilman Ave. extension), and will form part of a highway to the northwestern part of the city. For this new street, over 50,000 cu.yd. of earth were excavated and deposited on tide flats as filling for new freight yards and terminals.

part of the material excavated from the cut on the south section of the line revision was used in filling these trestles, where at high tide the water reaches a maximum depth of 27 ft. A bulkhead was constructed of piles, plank, brush and rock to retain the fill. About 100,000 lin.ft. of piling and 515,000 ft. b.m. of timber were used in the construction of the bulkhead, behind which 560,000 cu.yd. of earth fill was placed. The bulkhead was reinforced with 12,000 cords of brush and 90,000 cu.yd. of loose rock, delivered on scows from across the Sound. By filling the trestles, the railway company eliminated a heavy annual maintenance expense and reclaimed 16 acres of land.

Bridge over Salmon Bay

The double-track steel bridge crosses the Salmon Bay Waterway approximately 1000 ft. west of the entrance to the lock of the U. S. Government canal. The channel width is 150 ft., but as the bridge is on a skew (67° 37'), the bascule channel span is 200 ft. long c. to c. of bearings. The base of rail is 65.25 ft. above low water. The bridge, Fig. 1, is 1140 ft. long, with 725 ft. of double-track plate-girder spans; 235 ft. is open-deck construction and 490 ft. (over city streets) is the standard ballasted track section on reinforced-concrete deck slabs with

Fig. 2. Plan of Relocation of Great Northern Ry. at North End of Seattle, Wash.

As electric street-car tracks crossed the new line, the railway agreed to relocate these tracks on the new boulevard, which gave them a better grade and a more direct route, and avoided interference with the construction work. The street-car company has since secured a franchise for continuous operation at the new location.

Temporary bridges were constructed to accommodate street traffic over the cut. These were removed after the cut was completed to grade, and other bridges constructed at the streets which were not vacated. Over 1,250,000 cu.yd. of earth were excavated on the south section, of which 750,000 cu.yd. were taken from the cut for the new tracks. On account of the extreme depth of the cut, the steam shovels worked in tandem, one above the other. This eliminated the danger of slides and facilitated handling the cars. Standard railway equipment was used throughout this section of the work, and conveyed the excavated material from two to six miles through the terminal yards.

Filling the Tide Land Trestles

From Interbay the line follows the Seattle water front for over two miles on creosoted-pile trestles. The greater

curb walls (Fig. 1). The channel is crossed by a 200-ft. Strauss trunnion bascule span, with a 54-ft. girder span at the trunnion end (north), and a riveted-truss through span of 165 ft. at the south end. The steel girder approaches and the 165-ft. truss span were erected in advance of the bascule span, which was assembled and riveted in the open position (82°). This span is operated by two 100-hp. electric motors; it has also a 25-hp. gasoline engine for the gear auxiliary power, and emergency hand gear.

Bridge Substructure

The substructure comprises 17 piers and two abutments. Piers Nos. 1 to 6 were built first, and then Nos. 11 to 17. The piers in the waterway, Nos. 7 to 10, completed the third section. Borings indicated blue clay, with pockets of sand and gravel and traces of water; hence concrete piling was specified for the foundations of all land piers and timber piling for the waterway piers. Actual excavation, however, indicated that piling was not required, and all pier footings were redesigned for a total loading of 3 to 4 tons per sq.ft., actual soil tests being carried out for all piers.

The concrete was proportioned 1:3:6 for the footings, and 1:2½:5 for the batter and reinforced portions of the piers. Separate concrete plants were erected for construction of piers 1 to 7 on the south side, and piers 8 to 19 on the north side. In each case the sand and gravel were unloaded from scows and cars by a clam-shell bucket hoist, which delivered it to receiving bins, whence it ran by gravity to the mixers. The concrete was elevated in towers, and distributed by gravity through wood chutes to the different piers, except that for the piers at the extreme ends it was delivered by carts on elevated platforms.

The original specifications provided that the waterway piers should be constructed in open coffer-dams, but the bids on this feature showed that for Pier No. 7 (the pier carrying the truss span and the movable end of the bascule) a great saving could be made by using some other method. The method adopted consisted of preparing and sinking a timber crib for the base of the pier and depositing the concrete through a tremie up to an elevation of 4 ft. below low water. The crib was constructed in the water, floating at the site of its permanent location, where a dipper dredge had previously located the pocket for the pier base to a depth of 50 ft. below high water (7 ft. below the ultimate bottom of the canal).

The crib was 25x70 ft., and 53 ft. high. Extreme care was exercised in fastening the timbers so as to form one unit. It was divided into four sections with cross timbers spaced 4 to 6 ft. apart. The horizontal timbers were bolted to the vertical timbers which anchored the whole crib and provided against separation due to flotation. On account of a tidal range of 18 ft., it was difficult to keep the crib properly balanced and anchored; twice it tipped on its side and had to be righted.

The completed crib was sunk into place during low tide by loading it with steel rails placed in pockets or racks on the outside. On account of the slightly uneven bottom, the crib did not rest in a perpendicular position after being sunk, and as the cutting edge had no effect on the hard subsoil this was removed by a sea diver who succeeded in bringing the crib to within 6 in. of being truly perpendicular on the longitudinal axis.

The tremie was of heavy 10-in. wrought-iron flange-connected pipe, and was made in sections so that it could be shortened as the concrete mass increased in depth within the crib. The concrete was delivered to the tremie by a gravity chute, which greatly facilitated the work. A total of about 1100 cu.yd. of concrete was delivered to the crib in a continuous mix. The charge in the tremie was lost only when the tremie was lifted from one section of the crib to another. The concrete was made rich with cement (1:1.75:3.17), and the gravel aggregate was a fine grade. No coarse gravel was allowed and this seemed to result in a good steady flow through the tremie.

In order to dry the upper portion of the crib, clean the top concrete and prepare for the upper form work, the old method of inclosing the crib with canvas was used with success, after several other methods of calking the seams, etc., had been tried. After the canvas was placed around the crib, two centrifugal pumps (8 in. and 6 in.) kept the interior of the crib dry and the balance of the concrete was placed in the open. This pier is shown in Fig. 3.

The two smaller piers on the north side of the waterway (carrying the tower at the trunnion end of the bascule) were so located that a coffer-dam could be constructed around them and the work carried on in the open. Round piling constituted the outside and inside stiffeners. Wakefield sheet piling was then driven within this and tied with steel rods and the whole interior filled with earth. Within the dam, 4x8 in. sheet piling was driven to prevent the earth from sliding into the pier pits. The bracing was of 10x10-in. timbers, placed in tiers about 4 ft. apart as the excavation progressed.

At high tide, the water reached a maximum depth of about 27 ft., thus subjecting the dam to alternate stresses, which would not allow the core of the dam to become set or hardened. A very disastrous blowout occurred at one of these periods and the whole work within the dam was submerged. After the dam was repaired the excavation was retarded by the great amount of silt which had entered at the time of the blow-out. A unique method of

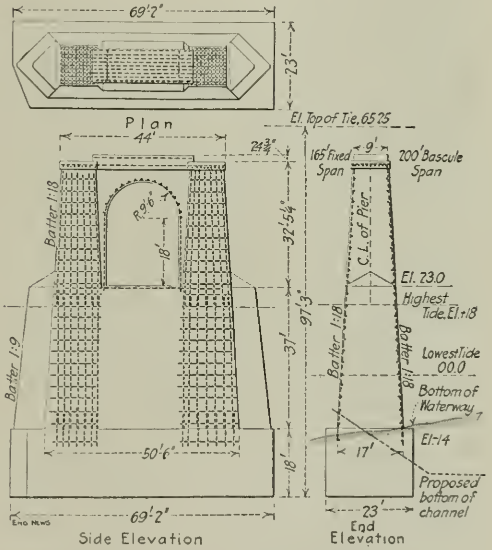


FIG. 3. REINFORCED-CONCRETE REST PIER OF THE BRIDGE OVER THE SALMON BAY WATERWAY; GREAT NORTHERN RY.

draining the water from the silt and mud consisted in sinking two wells on each side of the inside area. The water was then drawn from the wells by the centrifugal pumps and the excavation continued in the dry. At a depth of 50 ft. below high tide, the excavation was stopped, and the concrete was delivered through long wooden chutes to the forms built within the dam.

A total of 10,861 cu.yd. of concrete was placed in the substructure of the bridge, the railway company furnishing all the cement. A total of 17,888 cu.yd. of earth was excavated for the piers and abutments; 6065 yd. of this was included in the lump sum bid of preparing the three waterway piers for concrete, the balance being paid for as dry and wet excavation. The substructure was completed in 13 months by the Butler Construction Co., of Seattle.

Undergraduate Instruction in Highway Engineering

By T. R. Agg*

In attempting to outline collegiate work in highway engineering it is well to consider what kinds of things a graduate ought to know about highway work in order to become a useful member of the profession; and as many of these subjects deemed important should be taught as time and equipment will permit.

The conditions under which a college graduate will work when he first secures a position are exceedingly diverse in the various parts of the United States and the kind of specialized training in highway engineering that might fit a student admirably to take up the work in one state might not be so advantageous to him elsewhere. It would seem then that a training in highway work should first include those things which are of the nature of basic principles and generalities rather than those things which are matters of detail.

ETHICAL STANDARDS—The graduate should first of all realize that throughout his career he will deal with the public and with public officials. In his relation to the public he may become a leader or exemplar of the ideals of public service, which are economy and efficiency. He may drift along without giving offense to anybody and without accomplishing anything progressive; or he may ally himself with some political faction and conduct all work assigned to him in accordance with the well known principles of partisan politics rather than those of highway engineering.

No subject can be introduced into the technical training of the student that will have any particular bearing on the ethical standards which he sets up for himself. But the members of faculties have an unsurpassed opportunity to instill by personal contact the broad principles of professional integrity and a realization of the dignity and honor that may accrue from public service.

HIGHWAY ECONOMICS—The financing of highway and pavement construction involving as it does important economic principles, deserves a place in highway engineering instruction. Because of the ever increasing taxes which are levied for public improvements the time will come when engineers will be compelled to justify proposed expenditures by arguments which are economically sound. The choice of type of construction, the methods of financing and the extent of plan construction and maintenance are continually [illegible], and the bearing of each on any problem can be rightly determined only when the principles of economics and efficiency are applied. The basic principles of highway economics are comparatively few and may readily be given as supplementary to the work in general economics, which is included in many engineering courses.

ORGANIZATION AND ADMINISTRATION—The trend of highway administration is toward centralized authority such as is vested in County, State and National Commissions or Departments, and there is reason to believe that that tendency will be extended to include paving of cities and the performance of other public works. Such a development seems inevitable if the administration of highway work continues to increase in efficiency and to substitute sound engineering and economic principles for political chicanery in the building of highway structures. Highway engineering should, therefore, include a study of the methods of highway administration in effect in the United States and abroad and a comparison of the quality and cost of the roads produced by them, and of the safeguards thrown about the expenditures of public money in the various systems.

ROADS, PAVEMENTS AND HIGHWAY BRIDGES—The highway engineer should have a thorough knowledge of all of the types of the structures which he may be called upon to build, that is, of roads, pavements and highway bridges. The student should learn the history and the characteristics of each type, and the conditions of service for which each is adapted. He should know the underlying principles involved in the selection of a particular type for use under a known set of conditions. Many colleges now offer a course in roads and pavements that meets this requirement, or that could readily be modified to meet the needs of men who are preparing for highway work.

SURVEYS AND PLANS—The implements with which the highway engineer works are plans and specifications and the making of surveys is of course a prerequisite to the preparation of plans. The surveys for road and pavement plans do not involve any principle beyond those taught in courses in surveying in all colleges of good standing. Differences in the details of the methods of making the surveys are numerous, but these are usually easily and quickly mastered, and can readily be adapted to the requirements of different state and county authorities. It is a waste of time to attempt to teach the many special methods of making highway surveys to students in highway engineering.

The average plan prepared for highway or pavement construction, however, leaves much to be desired in the interest of completeness and clearness. The preparation of the plans involves the application of correct principles of highway design. It is believed that a course prepared in such a way as to emphasize the principles of correct design and the importance of complete and easily interpreted plans could properly be given to students in highway engineering.

CONTRACTS AND SPECIFICATIONS—A contract to build a highway structure or a pavement is a bargain between an individual or corporation and the public, the terms of which are set forth in the specifications. It follows then that these conditions should be set forth in clear and unequivocal English, that they should be concise and complete and be free from ambiguity, yet be drawn with a full understanding of the difficulty of anticipating all conditions, and therefore, providing for an equitable adjustment of all unforeseen contingencies. A course in highway specifications is an excellent adjunct to a course in roads and pavements because of the emphasis the writing of specifications puts upon each step in the construction.

Specifications for pavements are often drawn by attorneys rather than by engineers, or, they are copied from other specifications which have been in use. There is no valid reason why this should be true except that engineers have not given sufficient time or attention to the study of contracts and specifications. A course in the preparation of contracts and specifications for road and pavement work is, therefore, advisable as a part of the training for

*Professor in charge of highway engineering, Iowa State College, Ames, Iowa.

highway engineering. In many cases this work could be substituted for the general course in contracts that is usually given in engineering schools and thus avoid duplication.

NONBITUMINOUS ROAD MATERIAL TESTING—That the highway engineer should have a thorough knowledge of the materials used in construction and of the methods of testing and the significance of the results of tests is evident. Although much work remains to be done before all of the various tests for road materials will be standardized, there is now sufficient knowledge on the subject to warrant the introduction of a course in nonbituminous materials testing in a course in highway engineering.

BITUMINOUS MATERIALS TESTING—The very rapid development of bituminous road and pavement construction and the probability of a continued increase in the amount of this type of pavements makes it imperative to give some practice in bituminous materials testing. As with nonbituminous materials, much work remains to be done before all tests for bituminous materials can be standardized, yet sufficient knowledge and experience has been gained to enable the engineer to determine by suitable tests, with a fair degree of certainty, the value of any material submitted to him. In this work experience is of the utmost value, but if the routine tests are taught to the student, and he goes into the field of bituminous construction, he will rapidly learn to correlate the results of tests with the behavior of the materials in service.

DEVELOPMENT OF COURSES IN HIGHWAY WORK

There are two general methods that may be followed in the development of highway engineering, one being to give a 4-year course in highway engineering, the other being to permit students in civil engineering to take special work in highway engineering during the junior and senior years.

If a 4-year course is built around the instruction in highway engineering it will certainly be desirable to give during the first two years some of the usual general subjects if the student is to achieve the mental development necessary for a broad career. The last two years way engineering to the exclusion of such subjects as might be devoted very largely to subjects related to highway engineering to the exclusion of such subjects as water-supply, sewers, sanitation and general structures. Sufficient time would thus be available to cover practically the entire field of knowledge relative to highway construction.

If the option method were followed it would only be possible to teach the student where the facts in regard to highway construction may be obtained, how they may be used, and the general principles and the experience which are behind these facts. He could be taught to analyze a specific problem or situation in accordance with the recorded knowledge of highway engineering, and to find the solution, and to know when he had the correct one. A course of this kind necessitates spending much time in the study of mathematics, chemistry, physics, mechanics and allied subjects which are essential to the development of clear thinking and reasoning ability, and to the analysis and solution of problems.

If a course in highway engineering is developed along this line it simply involves substituting in the junior and senior years in the ordinary civil-engineering course a few subjects directly related to highway engineering. These subjects, in general, would displace other subjects of no greater value as general training. This procedure has the invaluable advantage of detracting but little from the possibility of a student's getting into other lines of engineering, if the field of highway engineering does not suit him, or if he fails to find his place therein.

The average undergraduate student has no clearly defined ideas as to what kind of work he wants to do after graduation, and many things may develop during his college years to change his ideas as to his future career. The college ought, therefore, to do everything possible to make well developed, clear thinking men, at the same time giving some practical preparation that can be used upon graduation to insure bread and butter while the man is finding himself.

The factors which make for success in the field of highway engineering are not primarily high scholastic attainments and great technical ability, although the more of these the man has the better, so long as some other things are included in his make-up. Ability to meet men of all classes, to deal harmoniously with other public officials and to address public meetings, coupled with a keen appreciation of the responsibilities and opportunities of public service are qualifications which weigh heavily in favor of the man who enters the field of highway engineering. If to these qualities is added a thorough training in the fundamental principles and practices of the profession of highway engineering, the graduate should be able to find an opportunity for a broad career in highway work.

It is suggested that the following subjects might be inserted in the junior and senior years of the ordinary civil-engineering course and thus give about all the desirable undergraduate instruction in highway engineering, and at the same time displace few studies of any more general value as mental training:

(1) HIGHWAY ECONOMICS—Second semester junior year, two credit hours. A study of the relation of highway improvement to the economic welfare; the principles of taxation for public improvements; and of financing road and pavement construction.

(2) ROAD AND PAVEMENT SPECIFICATIONS—First semester senior year, two credit hours. A study of the basic principles of specifications, and of the details of form and wording. This might be supplementary to the course in contracts and specifications often given in engineering courses.

(3) ROADS AND PAVEMENTS—First semester senior year, two or three credit hours. A study of the types of roads and pavements, methods of constructing them, and their relative values under varying conditions of service. This could be an adaptation of the usual course in roads and pavements, or, in many cases, the course in roads and pavements already being given would suffice.

(4) NONBITUMINOUS MATERIALS LABORATORY—First semester senior year, one credit hour. A study of the methods of testing nonbituminous road materials and of the significance of the results of tests.

(5) HIGHWAY ADMINISTRATION—Second semester senior year, two credit hours. A study of the methods of organization and administration for highway construction, including systems of maintenance.

(6) ROAD AND PAVEMENT DESIGN—Second semester senior year, three credit hours. A study of the principles of design of roads and pavements, exercises in the preparation of plans and estimates for road and pavement construction.

(7) BITUMINOUS ROAD MATERIALS LABORATORY—Second semester senior year, one credit hour. A study of the usual tests for bituminous road materials and of the application and significance of these tests.

(8) DESIGN OF HIGHWAY BRIDGES—Second semester senior year, two credit hours. A study of the design of the various types of highway bridges and culverts. This might well be given in connection with the course in structural engineering.

A Rating Chart for Centrifugal Pumps

By L. J. Beauford*

When an order for a centrifugal pump is given, usually the conditions under which the pump is to operate are stated and the selection of the pump to meet these conditions is left to the makers. The manufacturer's engineer makes his selection by reference to a rating chart which shows the performances of various stock pumps correctly.

The purpose of this article is to show how to lay out and use a graphical rating table which greatly facilitates the selection of a pump when the required speed, head and capacity are given. The chart is in reality a collection of speed-capacity characteristics of all the pumps of a given line, each operating at unit head, and over a certain range of efficiencies. It is usually laid out for one stage, but can easily be constructed for any number of stages. In this article only the chart for single-stages will be dealt with.

Before taking up the method of laying out the chart, it is necessary to call attention to the peculiar characteristic curve upon which it is based. Fig. 1 shows this. Unlike the ordinary performance curves, it is not drawn with head and capacity for coordinates, but with coefficients of peripheral velocity of the impeller and of radial exit velocity of the water. These coefficients are derived as follows:

$$K_u = \text{coeff. peripheral vel.} = \frac{U_2}{\sqrt{2gh}} \qquad (1)$$

$$K_{cr} = \text{coeff. radial exit vel.} = \frac{V_{cr}}{\sqrt{2gh}} \qquad (2)$$

U_2 = peripheral velocity of outside of vanes in feet per second;

V_{cr} = radial velocity in feet per second of water leaving impeller;

h = head per stage developed by pump;

g = acceleration due to gravity = 32.2 ft. per sec. per sec.

The coefficient K_u is the ratio of the actual speed of the impeller to the theoretical velocity of the water necessary to produce the head h. It may be either greater or less than unity, and depends largely upon the angle which the vanes make with the tangent to the outside of the impeller. In general, a forward curving vane will give a value of K_u less than unity, a radial vane unity, and a backward curving vane greater than unity. The coefficient K_{cr} also depends to a certain extent on this angle.

*[illegible]

When a new line of pumps is to be designed, a pump having the desired shape of characteristic is tested, and the $K_u - K_{cr}$ characteristic is plotted as shown in Fig. 1. Next, the values of the coefficient of discharge velocity for the various sizes of pumps to be made are assumed. The values of these discharge coefficients,

$$K_d = \frac{V_d}{\sqrt{2gh}} \qquad (3)$$

where V_d = velocity of water in the discharge pipe in feet per second, are such as former experience has shown to give good results. Fig. 2 shows graphically how the values of the discharge coefficient may vary with the size of the pump. Having assumed the discharge coefficient, the capacity of a pump for a unit head can be computed. The following notation will be used:

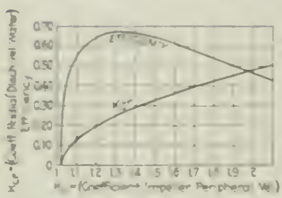

Fig. 1

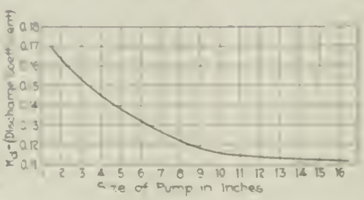

Fig. 2

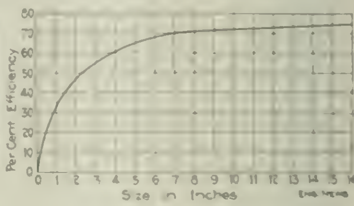

Fig. 4

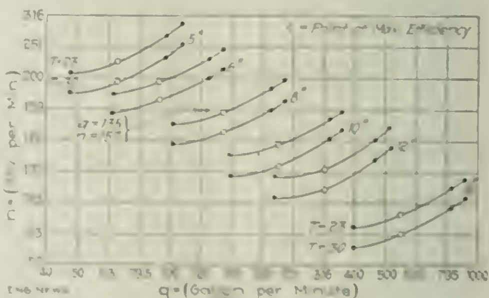

Fig. 3

Q = pump capacity, cubic feet per second;

N = r.p.m.;

K_d = discharge coefficient = $\frac{V_d}{\sqrt{2gh}}$ (3)

d = diameter of discharge, inches;

h = head per stage;

A = area of discharge, square feet, = $\frac{0.7854\,d^2}{144}$;

q = capacity of pump at unit head = $\frac{\text{gal. per min}}{\sqrt{h}}$

n = speed of pump at unit head = $\frac{\text{r.p.m.}}{\sqrt{h}}$;

D_2 = outside diameter of vanes, inches;

W_2 = width of impeller passage at exit;

T = type of impeller = $\frac{D_2}{W_2}$ (4)

Now

$$Q = \frac{q\sqrt{h} \times 231}{1728 \times 60} \qquad (5)$$

also $V_d = \frac{Q}{A}$, and by substitution,

$$V_d = \frac{q\sqrt{h} \times 231 \times 144}{1728 \times 60 \times 0.7854\, d^2} \qquad (6)$$

now by dividing both sides of this equation by $\sqrt{2gh}$, simplifying and remembering that $K_d = \frac{V_d}{\sqrt{2gh}}$ we get

$$K_d = \frac{q}{19.6\, d^2} \text{ or } q = 19.6\, K_d \, . \, d^2 \qquad (I)$$

From this equation the value of the discharge at unit head, or, as it is more frequently called, the "unit capacity," may be computed as soon as values are assigned to K_d and d. The speed in feet per second at unit head, or "unit speed," is found as follows:

$$K_u = \frac{\pi D_2 N}{60 \times 12 \times \sqrt{2gh}} \therefore N = \frac{K_u \times 12 \times \sqrt{2gh} \times 60}{3.14 \times D_2}$$

Dividing by $\sqrt{h}$ and reducing,

$$n = \frac{K_u \times 1840}{D_2} \qquad (7)$$

Were the values of K_u and D_2 known, the chart could now be laid out. But D_2 is usually unknown unless the chart is being drawn for an existing line of pumps. Of course D_2 could be assumed, but it is usually preferable to assume the type T of the impeller.

Assuming that 85% of the total area of the periphery of the impeller is available for the passage of water, we have

$$W_2 = \frac{gal.\ per\ min. \times 231}{V_{ra} \times 12 \times 60 \times \pi D_2 \times 0.85}$$

Dividing the numerator and denominator on the right by $\sqrt{h}$

$$W_2 = \frac{0.015\, q}{K_{cr} \, . \, D_2} \qquad (8)$$

Substituting $\frac{D_2}{T}$ for W_2,

$$D_2 = \sqrt{\frac{0.015\, q\, T}{K_{cr}}}$$

Placing this value for D_2 in equation (7) there results,

$$n = \frac{15{,}025\, K_u \sqrt{K_{cr}}}{\sqrt{q\, T}} \qquad (II)$$

Values for q and n may be obtained for any size of pump using any type of impeller, the values of K_u and K_{cr} being taken from the test on which the line is based. Four values of q and n are usually computed for each impeller represented. The points usually taken are the point of maximum efficiency, 90% of maximum efficiency—at a capacity lower than that at which maximum efficiency is reached, and 95% and 90% of maximum efficiency—at greater capacities than for maximum efficiency.

Application

The use of these formulas can best be made clear by sample computations. Take for example the case of a 6-in. pump.

d = 6 in.;
K_d = 0.132 (based on tests of existing pumps which give good efficiency. See Fig. 2);
T = 23 (assumed);
K_u = 1.25 (from test, see Fig. 1 and Eq. 1);
K_{cr} = 0.22 (from test, see Fig. 1 and Eq. 2);
Maximum efficiency = 67% (from test, see Fig. 1).

Calculation of q and n for 100% of Maximum Efficiency

$$q = 19.6 \times 0.132 \times 6 \times 6 = 93 \qquad \text{(from Eq. I)}$$

$$n = \frac{15{,}020 \times 1.25 \times 0.47}{46.2} = 192 \qquad \text{(from Eq. II)}$$

Calculation of Other Than the Point of Maximum Efficiency

Since K_u and K_{cr} are respectively directly proportional to the peripheral velocity of the impeller and the radial velocity of the water, it follows that n and q are, for a given pump, directly proportional to K_u and K_{cr}, respectively. If, therefore, it is desired to find the values of q and n with the pump operating at other than maximum efficiency, it is necessary only to write the following equations and solve.

$$n_x = \frac{n_{100} \times K_{ux}}{K_{u_{100}}} \qquad (III)$$

$$q_x = \frac{q_{100} \times K_{crx}}{K_{cr_{100}}} \qquad (IV)$$

If it is desired to find the values of q and n when the pump is operating at 90% of its maximum efficiency, and delivering less water than it would at maximum efficiency,

$$efficiency = 0.90 \times 0.67 = 0.603$$

By reference to the impeller-velocity characteristic (Fig. 1), it is seen that the values of K_u and K_{cr} corresponding to an efficiency of 60.3% and a minimum discharge are $K_u = 1.15$ and $K_{cr} = 0.155$. Substituting in equations III and IV,

$$n_{90} = \frac{192 \times 1.15}{1.25} = 177 \quad q_{90} = \frac{93 \times 0.155}{0.22} = 65.5$$

The points on the front of the curve, that is when the pump is discharging more than its normal amount of water, are found in a similar manner. Fig. 3 shows such a chart plotted on logarithmic paper for a complete line of pumps, sizes varying from 5 to 16 in., and for two types of impeller for each size.

Use of Chart—When an order for a pump is received the values of q and n are immediately calculated from the conditions of operation, by means of the equations $q = \frac{gal.\ per\ min.}{\sqrt{h}}$ and $n = \frac{r.p.m.}{\sqrt{h}}$, and the point plotted. The impeller having the next value of n below that found is taken, and if the difference is large the tips of the vanes are cut back. (This is done to bring the speed up to that required. It is readily seen that cutting back the vanes increases the speed when it is remembered that for any given impeller the outside diameter of the vanes must attain a certain peripheral velocity in order to produce a certain head.)

Suppose, for example, that an order came in for a pump to deliver 1500 gal. per min. against a head of 250 ft. when running at a speed of 1760 r.p.m. The pump will obviously consist of two stages, for while a head of 250 ft. per stage is possible, it can usually be attained only at the sacrifice of efficiency. The head per stage is then 125 ft.

$$q = \frac{1509}{\sqrt{125}} = 135 \qquad n = \frac{1760}{\sqrt{125}} = 157$$

The pump determined by these values of q and n is thus plotted as shown on Fig. 3. The impeller chosen will be the one having the next highest values of q and n. In this case an 8-in. pump having a type 23 impeller would be chosen and the same cut back a little. The pump would operate at about 98% of its maximum efficiency. From Fig. 4, it is seen that the maximum efficiency of an 8-in. pump operating at 125 ft. per stage is 71%. The efficiency of the pump selected would therefore be about 71% × 0.98 = 69.5%.

Moving Sand by Pumping*

A pump without pistons or plungers, especially designed for pumping sand or fine coal, was recently placed on the market. The operation is simple. The steam is admitted into one cylinder at a time, forcing out its contents. The vacuum in one cylinder and the pressure in the other drive over the steam-control valve. The steam by this operation is introduced into the chamber just filled with the pumped mixture. The pump operates without any mechanical parts and the only moving element is the steam valve, which has a movement of about $\frac{3}{8}$ in. The valves are either of the ball or flat type. Balls are used for the discharge valve and in some cases for the suction. The balls are usually of rubber; the flat valves are also of rubber.

The pump is claimed to have a very high vacuum and hence a strong suction, which, of course, is very necessary in sand pumping. The pump was patented in 1900 and placed on the market at that time, but it was not adapted for handling sand until recently. It is claimed that a mixture of at least 35 to 45% sand can be easily carried. Wherever the sand comes in contact with turns or elbows, the pump is heavily reinforced; parts of the casting are 2 in. thick. This pump can also be used for handling fine coal or crushed rock. The pump is built by the Nye Steam Pump & Machinery Co., 701 Northwestern Ave., Chicago, Ill.

AN INSTALLATION

The accompanying views show the pump in action at Fern, Ind., at the sand mine of the Root Glass Co. Until the pumps are installed, the mine was operated by numerous belt conveyors, and by sand-washing screws. By this familiar method, a certain amount of the sand washed was carried off by the water and lost. Traveling belts were costly to replace and wore rapidly.

At the mine, rock is reduced by blasting to about 70% sand. This sand is washed to a sump pit, located in the center of the mine, by means of water jets and is then

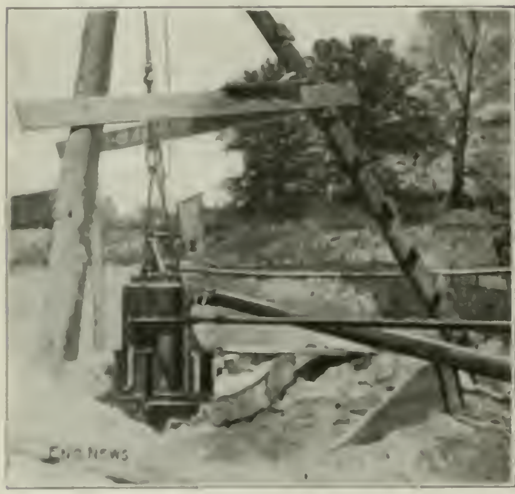

FIG. 1. PUMP IN OLD SAND-SETTLING BASIN

(Basin was to be emptied, so pump was installed temporarily to remove the storage sand.)

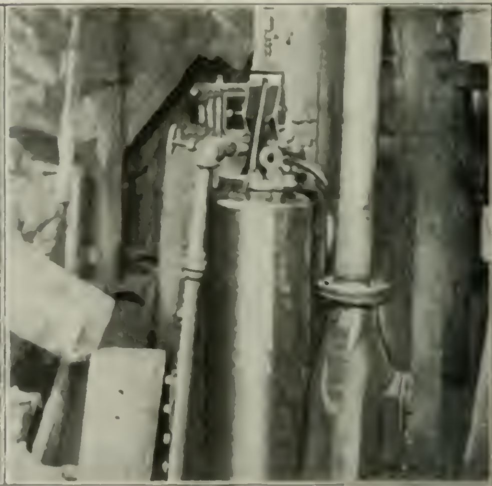

FIG. 2. NO. 5 PUMP, FERN, IND.

(All sand shipped from this mine passes through the pump shown.)

picked up by a 4-in. pump (5-in. suction and a 4-in. discharge) and discharged upon separating screens. Sand is then washed down to a sump in the building, located under a 5-in. pump (6-in. suction and a 5-in. discharge).

The rock at the mine, not broken up by the blast, is placed in a crusher, from which it falls into a sump, located under another 4-in. pump. The discharge of this pump with that of the first-mentioned pump is carried into the sump under the 5-in. pump. In this way, the latter pump handles all the sand to be shipped, elevating it vertically 35 ft. and horizontally 60 ft. to the cars. There it empties into a sand-and-water separator, which automatically opens and closes as the sand deposits in its bottom. The water in the separator rises to the top, runs over and is carried off by piping.

Not only is the sand conveyed through the action of the pump, but it is thoroughly scrubbed by its passage through it.

It is claimed that the installation of the pump caused

*Abstracted from information furnished by the Nye Steam Pump & Machinery Co.

the average production of this mine from 120 tons per day to 480 tons, and that whereas the cost of production by the old method was $2 per ton, the pumping method cost but 57c. per ton.

New Locomotive Terminal of the Central R.R. of New Jersey

The large new locomotive terminal of the Central R.R. of New Jersey, at Communipaw, N. J., is one of the principal features of the reconstruction of the passenger terminal at Jersey City, N. J., described in Engineering News, of July 30, 1914, p. 238. The locomotive terminal is located on the south side of the main-line tracks, about one mile west of the passenger terminal, and is in close proximity to the freight yards on the opposite side. It consists of two roundhouses governed by two connecting 100-ft. turntables. The number of locomotives handled per day in summer averages about 300, which includes all the usual performances of a terminal character, e.g., cleaning fires, dumping ashes, coaling, supplying sand and water, washing boilers, and inspecting, together with any light running repairs which may be necessary. The trackage of the locomotive terminal amounts to about 11 miles.

The soil is principally of cinder fill varying in depth from 2 to 10 ft. on blue clay, sand and bog. In consequence, all the buildings rest on piles, except the west half of one of the roundhouses, where the ground conditions are favorable for masonry footings. The foundations consist of timber piles and concrete piers where the concentrated loads are imposed, with reinforced-concrete wall girders supporting the building walls. The power house, which is in this group of buildings, rests on a concrete slab 4 ft. thick, extending under the entire building, which in turn is supported on piles equally spaced. All the buildings are constructed of reinforced concrete, steel and brick, with steel sash and concrete floors. The roofs are covered with 3-ply built-up asbestos-felt and asphalt roofing.

Power House—The power house, which furnishes power for lamps and motors throughout the terminal, is 125x92 ft. in plan. Six 250-hp. water-tube boilers arranged in three batteries of two each are installed; while space is provided for an additional battery. Automatic stokers are used. Draft is obtained with a 100-ft. steel stack and two turbine-driven blowers. Looped feed-water and steam lines are used. An open feed-water heater takes the exhaust of auxiliaries and raises the boiler supply to 200° F. The coal-and-ash-handling arrangements are such that the railroad cars used to bring in coal are loaded with ashes on the same track.

Three 600-kw. 2250-volt turbine-driven alternators are installed, with space for a fourth. Two 2500-cu.ft., compound, steam, two-stage air compressors furnish air for the engine terminal and for the interlocking system. The main control board is located on the engine-room floor, with the high-tension switches in the basement, with the transformers. High-tension current is led to a service substation near the passenger terminal and stepped down to 550, 220 and 110 volts. The lower voltages for use near the power station are secured from transformers in the basement.

Roundhouses—The two roundhouses—one 34-stall, 100-ft. and one 32-stall, 90-ft.—are constructed with reinforced-concrete piers, columns and roof girders, with

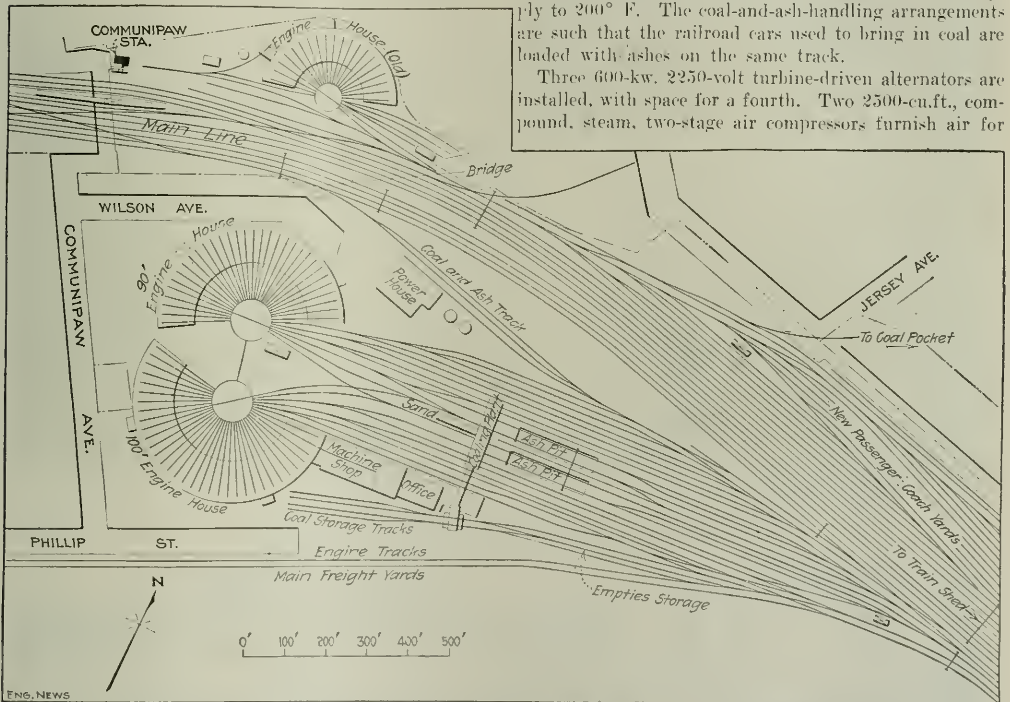

Fig. 1. General Layout of Locomotive Terminal of Central R.R. of New Jersey

hollow tile and concrete walls. The rear wall consists of concrete piers approximately 3 ft. wide with steel sash between. This arrangement permits of a maximum window space, both for lighting and ventilation. A row of hinged sash is provided over each stall. There are other ventilators as well, which provide an outlet for any gases collecting under the ceiling. Both houses are heated by the indirect system. The fans and heaters are located in fan houses, of which there are two in each building.

FIG. 2. INTERIOR OF ONE OF THE TWO ROUNDHOUSES

(Showing transite pits and asbestos-board smokejacks.)

The hot air is delivered through underground ducts and discharged through outlets located in the pits and around the rear wall. The floor wearing surfaces are concrete throughout and reinforced along the sides of the pits to provide bearing for jacking.

The entrance doors to the stalls are hinged on plate frames which are entirely separate from the building construction proper, and so fastened to the building columns that the accidental wrecking of a door will not damage the building structure.

TURNTABLES—Each roundhouse is served with a 100-ft. turntable of heavy construction, operated by electric tractors. Owing to the extreme depth of these turntable pits and the shallow grade of the sewer in the vicinity it was necessary to provide against the sewage backing up into these pits by constructing a deep sump pit, into which both pits drain. Automatic ejectors discharge this drainage into the nearest sewer at a higher level.

COALING STATION—The main building of the coaling station spans eight tracks and serves an additional track at each end. It is 168x54 ft. in plan by 55 ft. high, and of reinforced concrete throughout. The bunkers rest on I-beam girders incased in concrete; the hopper bottoms are built of reinforced concrete and hollow tile.

There are three longitudinal bunkers, with a capacity respectively of 430 tons of bituminous, 813 tons of broken (anthracite) and 430 tons of buckwheat coal. These bunkers are divided into four compartments by transverse concrete partitions. Each track is served by three coal chutes, so that a locomotive on any one of the ten tracks may be coaled with either bituminous, broken or buckwheat coal.

The conveying machinery is divided into two separate and distinct units, each with a capacity of 100 tons per hour. The entire machinery is electric driven. Guards are placed over all exposed gears as protection to the attendants; and there are eleven emergency stations from which the entire machinery can be shut down by pressing a button.

West of the coaling station are the coal-storage tracks, with a capacity of forty cars. Provision is here made for thawing out frozen coal in the cars on these tracks, by means of live steam.

SAND HOUSE AND CINDER PITS—Sand is dried and stored in a building west of the coaling plant. It is of reinforced concrete, 100x16 ft. and 40 ft. high. After the sand is dried, it is screened and elevated by means of compressed air to two storage tanks of 15-cu.yd. capacity

FIG. 3. COALING STATION OF 1700 TONS CAPACITY

(Separate three longitudinal bunkers [illegible] each track is served by three chutes, one from each bunker. [illegible] shown at top of building.)

each, located on top of the coaling station. These tanks deliver sand to the locomotives through cast-iron delivery pipes; and 10 wrought-iron telescope spouts serve the ten tracks.

The cinder pits, which are of the submerged type, are located about 60 ft. east of the coaling plant; each is 200x30 ft. by 12 ft. deep, and of reinforced concrete. Each pit serves two tracks which are 26 ft. c. to c. The cinders are removed from the pits by electric traveling cranes, operating a 1⅝-cu.yd. clam-shell bucket. Aside from the economy and speed of handling engines over these pits, this arrangement permits of the coaling of engines from cars by means of the clam-shell bucket, should occasion arise.

A tunnel is provided from the power house to the roundhouse for carrying all steam, air and water piping, and also all wires and cables for lighting parts of the building. This tunnel is of heavy reinforced-concrete construction, waterproofed, 6 ft. wide, 10 ft. high, and 367 ft. long, with a branch running to the 90-ft. roundhouse. The tunnel is well lighted. The power cables to the station terminal are carried in a tile and concrete underground duct line located in a paved driveway just north of the new coach yards and station.

The locomotive terminal was built by Westinghouse, Church, Kerr & Co., and designed by them in coöperation with the Central Railroad engineers.

Interlocking System

While not a part of the locomotive terminal, the interlocking system which governs all movements into the new trainshed described in last week's issue, and all movements in and out the locomotive terminal proper will be described here. The first interlocking plant related to this whole reconstruction work to be placed in service, was the one at the Van Nostrand place, about 3 mi. west of the North River. Next, on Mar. 12, 1911, the interlocking plant at Communipaw was put in service. The latter plant, located just west of the Communipaw station, governs the movement of trains across the New York-Newark Branch into the freight yards south of the station, and on down to the water front; also the movement of freight and coal from the south side of the main-line track to the west end of the main freight yard, across the main line to the main Jersey City freight station on Jersey Ave., and to large coal pockets located north of the passenger-terminal yard. This plant also governs movements in and out of the new locomotive terminal.

The movement of trains into the trainshed is governed by two plants; No. 1, the larger, controlling the shed tracks, while No. 2 governs engines into the locomotive terminal. One 179-lever tower, located south of the main track, about 800 ft. west of the new trainshed, is being built, which will replace both of the older towers. Each track in the new trainshed will be provided with at least two means for entry or exit, reducing the chance of blockades as the towerman will have the choice of several routes.

The interlocking plants were installed by the Union Switch & Signal Co., Swissvale, Penn.

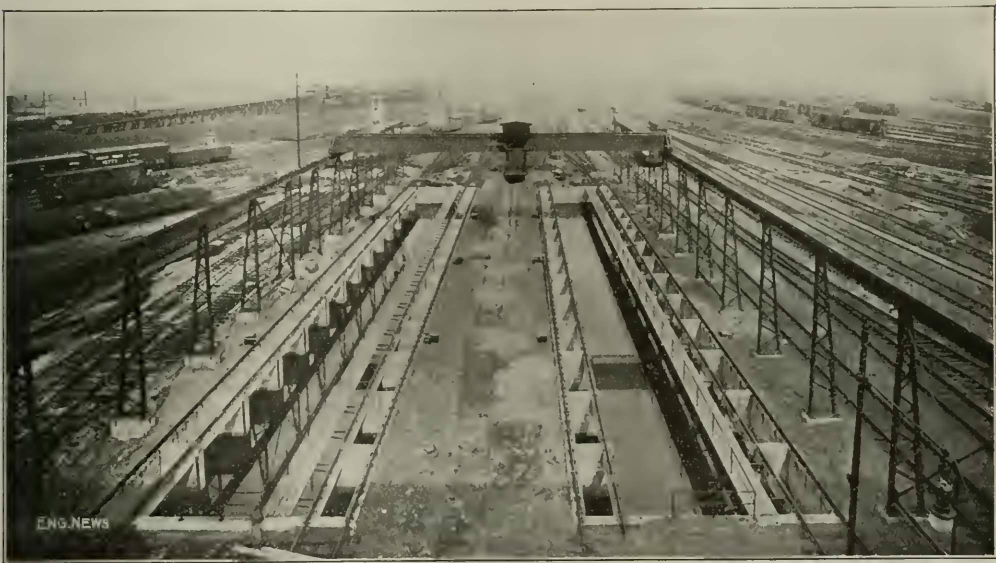

Fig. 4. The Cinder Pits

(Ashes are removed from the pit by a 1⅝-cu.yd. clam-shell bucket on the crane shown. This same crane and bucket can be used for coaling purposes should occasion arise.)

Passenger-Coach Yard

The new passenger-coach yard will cover the ground once occupied by the old coach yard, engine terminal, coaling plant, and repair shop, which are now situated west of the trainshed and at the new Communipaw engine terminal.

The new coach yard and interlocking system controlling the new trainshed tracks will contain about 35 mi. of trackage, of which 25 mi. is new construction, and

1 yd. 332 track relocated. All trackwork was installed by the railroad by its maintenance-of-way department.

Central Railroad Co. Organization

The construction work was accomplished under the supervision of the Engineering Department of the Central R.R. of New Jersey: J. O. Osgood, Chief Engineer; A. E. Owen, Principal Assistant Engineer; J. J. Yates, Bridge Engineer; A. M. Zabriskie and H. E. van Ness, Assistant Engineers of Design; and C. M. Titsworth, Assistant Engineer in Charge of Construction.

Difficulties in Initial Operation of a 110,000-Volt Transmission Line

By Frank G. [illegible]*

The freedom from operating difficulties which may be secured, even in the initial period of operation of a very high voltage electric transmission line, where proper attention has been paid to every detail of design and construction is illustrated by the experience of the Georgia Ry. & Power Co., with its Tallulah Falls line.

This system was first put into operation Sept. 20, 1913, and regular service began Oct. 17. As already noted (Engineering News, Jan. 29 and Apr. 16, 1914) the Tallulah system comprises the power house, transmission line, five substations and a terminal station in Atlanta. Power is generated at 6600 volts, stepped up to 110,000 volts and distributed over steel tower lines of about 275 miles in length. The ultimate capacity of the development will be 80,000 kw., the present installed capacity being 70,000.

Voltage was first impressed on the section between Tallulah Falls and Atlanta with all apparatus connected thereto, and regular operation continued to Dec. 22 without the slightest interruption from defective apparatus. At this time an insulator failed on an air-break switch at Buford, on a section of tower line between the power plant and the Atlanta terminal station. This caused an interruption to the service of 15 minutes' duration. The same trouble was experienced with the same insulator again on Feb. 10. On Mar. 14, the first insulator on the 110,000-volt tower line gave way on the branch section between Atlanta and Newnan. This was the first line trouble encountered after the operation was begun and in fact has been the only trouble to date. There was no loss of insulators or equipment when voltage was first put on the lines, and the interruptions mentioned above are the only ones which have been encountered due to defective equipment. This is very remarkable, considering the large number of substations and switching stations which are connected to the lines where insulation trouble is so liable to occur. There has been no loss of transformers, or any electrical equipment of any character except a few small instruments such as current transformers and high-tension bushings; these did not cause any interruptions but simply showed weakness and had to be removed.

There has also been unusual success in the operation of both high-tension and low-tension electrolytic lightning arresters. These arresters have been charged repeatedly since operation was begun without the slightest noticeable disturbance to lines or apparatus, nor have the disturbances been reflected to any indicating instrument.

The engineering design shows many points of individuality and no money was spared to secure permanent safety of mechanical details. Aside from points discussed in earlier articles, the following are of interest.

The generators were among the first water-power machines to have spiders of rolled-steel plate to avoid possible unseen defects in steel castings—an important factor in protection against mechanical failure of a high-speed rotating element. This is especially important when it is considered that all waterwheels are liable to attain runaway speed, and in some instances actually have with disastrous results. Furthermore, the rotors in the machines are designed to hold a runaway speed of 1.7 times normal for one hour (maximum kinetic energy about 1,250,000 ft.-lb.).

Again, in anticipation of unavoidable serious variations in electrical operation, the generators are designed for an excitation of not more than 250 volts, normal ex-

Exterior and Interior of Telephone Station; Transmission Tower, Showing Main Line Cables (Above) and Telephone Wires (Below)

*[illegible], Consulting Engineer, [illegible] Broadway, New York City.

citer voltage, at 10,000-kw. load, 80% power factor and generator voltage of 7260 (normal voltage being 6600). This design for adverse conditions makes possible an absolute control of generator voltage, even under the worst possible line conditions, giving sufficient leeway to vary the voltage through a wide range of power factor without ever exciting the generator fields. This has been found of further value since the generators operate at normal rating with almost no temperature rise, making it feasible to increase the normal rating of the machines if such should be necessary under average operating conditions.

The high-tension wiring of the switch house is of copper tubing with bends made to fit designed forms and supported so as to give symmetry and the appearance (as well as the fact) of mechanical permanency to the entire layout. Where the high-tension wiring leaves the switch house, instead of the usual wall bushings (with a weather housing apparently intended to apologize for their inefficiency) oil-filled 150,000-volt wall bushings of special design are used, requiring no outside covering; when designed these were an advanced and original construction but one now coming into broader use.

The steel towers bore two ground wires and were considerably heavier than any heretofore installed in the South—the idea being that the cost of some extra metal is much cheaper than one failure and the consequent effect on the service. In the design of these towers particular attention was given to the condition of the heavy sleet which they would be called upon to withstand in this territory (a historical fact).

The substation in Atlanta in addition to being the largest outdoor type in the world, embodies features equally original. Special attention has been given as far as possible to eliminating high-frequency disturbances at the station, and this has been effected by unique but simple arrangements. The lightning arresters are tapped off at the end of the incoming lines as usual—but the horn gaps and arrester tanks are placed so as to furnish a straight path from the line to the tanks, enabling the latter to receive the dynamic blow of any oscillatory discharges while the power lines are turned through two right angles and a choke coil before entering the substation.

It might be interesting also to note that many of the high-voltage lines previously put into operation have been operated at a voltage considerably lower than that for which the lines were designed; for instance, lines designed for 110,000 volts have usually been operated at but 88,000 and for 140,000 volts have been operated at 120,000. This system herein referred to was designed for 110,000 volts and is actually operated at from 111,000 to 118,000.

The chief difficulty which has so far been experienced in the operation of this system has been one which has occasioned difficulty on all systems of high-tension lines. That is with the telephone line. This is of No. 4 copper-clad steel wire, strung on the steel towers some distance beneath the power wires. The telephone booths consist of portable sectional station houses—painted dark green and stationed within the square steel towers.

The telephone wire was originally supported on pin-type insulators—but it was found it could not thus be kept insulated from ground as the insulators punctured almost as rapidly as they could be replaced—and the service was extremely unsatisfactory. After several schemes failed, the entire line was restrung on high-voltage insulators. This was done between Tallulah Falls and Atlanta (about 90 miles), using suspension-type insulators with a special "S" hook. Now the talking is excellent and uninterrupted. Exhaustive tests and numerous oscilligraph records have shown the actual induced effects on the telephone line due to the power lines above. These data could not be secured with the line as first constructed because of the poor insulation, and have probably never before been secured with a similar transmission system; they should greatly influence the future design of such systems. The potential to ground induced on the telephone lines is between five and six thousand volts, and checks very closely with the theoretical. This potential, however, can be lowered somewhat by the use of a special drainage coil of heavy current capacity; there is also other protective equipment, like horn arresters, disconnecting switches, insulated platforms, etc.

In many cases it has been necessary to do switching with both low- and high-tension oil switches, but no damage has resulted to any equipment, and no surges of any consequence have been set up on the line as a result.

One incident of interest occurred at the power house. Lightning struck one of the feeders running to the Southern Power Co.'s system near the power-house building. The surge entered the building through the high-tension wall bushing, followed the high-tension wiring through the oil switch and was reflected by the transformers back to a post-type insulator which flashed through the brickwork to the steel column inclosed therein, a distance of some four feet and then went to ground. The only serious result was the loss of the copper tubing connecting the terminals of the transformer. This disturbance occurred, however, before the installation of the electrolytic arresters on this feeder, and the feeder was not protected by any other similar apparatus.

A similar incident occurred on June 4, when the entire district was visited by a severe lightning storm. The Tallulah system remained in operation, while several of the adjoining systems were repeatedly knocked out, the only effect felt on the Tallulah lines being a momentary drop in voltage of approximately 40%. This caused a few railway rotary converters in Atlanta to drop out of service for a few minutes, and occurred twice.

Charles O. Lenz, 71 Broadway, New York, was the chief engineer for the entire development from preliminary report to completion. C. E. Bennett has been the Assistant Electrical Enginer in charge of construction.

✱

The Increasing Weight of Railway Rolling Stock—In 1829 a locomotive with two axles coupled, running on rails weighing 34.2 lb. per yd. weighed 5 tons, which was equal to 300 times the weight of rails per meter.

In 1846 an engine with three axles coupled, weighing 22 tons, ran on rails weighing 84.6 lb. per yd. This came to 630 times the weight of rails per meter.

In 1880 an engine with four axles coupled, weighing 56 tons, ran on rails weighing 81.6 lb. yer yd. This came to 1330 times the weight of rails per meter.

In 1911 a six-axle-coupled Golsdorf engine, weight 96 tons, on rails weighing 96.77 lb. per yd., gave a ratio of 2000. In 1911 also, in the United States, a "Mallet" engine with ten axles coupled, weighing 245 tons (adhesive weight), represented a ratio of 4600 times the weight of rails of 111 lb. per yd.; but this ratio, which is very high, is due to some extent to an exceptional weight per axle.

If adhesive force be taken as one-sixth of the weight, it will be found that the ratio of the tractive force at wheel tread to the weight of rails per meter has varied according to the values: 50—105—225—333—750.—Anatole Mallet before the Paris meeting of the Institution of Mechanical Engineers.

Recent Railway Construction in Chile

By Charles P. King*

SYNOPSIS—The Chilean Longitudinal Ry. is a part of the projected Pan-American Intercontinental Ry. Only a short section of about 93 miles of the Longitudinal Ry. remains to be built. This article describes in detail the general features of the line from Tacna to Port Montt, 2200 miles long, mentioning and describing connecting railways to the coast, and all the other principal railways in Chile, projected, under construction and completed. The effect of recent railway construction on the development of the mining industry is outlined. Much information is given about the needs and expected expansion of various industries for the benefit of engineering, contracting and equipment companies.

With the joining of the rails of the northern and southern sections of the so-called Chilean Longitudinal Ry. at Yerbas Buenas, about 70 miles north of the port of Coquimbo, on Nov. 22, 1913, Chile has almost completed its part of the proposed Pan-American Intercontinental Ry. Only a short section of about 93 miles, which will connect Arica in the north with the Nitrate Ry. at Jaz Pampa, now remains to be built in order to give to Chile a great trunk line over 2200 miles long, running due north and south from Tacna in the extreme north to Port Montt at the end of the habitable part of Chile in the south.

By far the greater part of this system has been built by the Chilean Government and is under Government control; and about 1000 miles of this has been built within the past three years. Unfortunately, a uniform gage does not exist, due to the fact that some of the connecting links of the system were built some years ago; but by far the greater part of the system between Arica and Santiago, the capital, is meter gage. Between Santiago and Port Montt it is all 5-ft. 6-in. gage. Between Tacna and Arica, in the extreme north, an English company has been operating about 37 miles of 5-ft. 6-in. gage railway for many years past. This road forms the first link of the Chilean portion of the Pan-American Ry.

Proposed Arica to Jaz Pampa Section—Between Arica and Jaz Pampa, a distance of 93 miles, the government will soon build a meter-gage railway. From Jaz Pampa, about 30 miles inland from the seacoast [illegible] Pisagua, the Pan American Ry. is continued a distance of about 155 miles to Pintados, over the lines of the Nitrate Railway Co., Ltd., another English company operating a [illegible] line [illegible] between the ports of Pisagua and Iquique, serving the many nitrate works back of the coast in this section.

Pintados and Pueblo Hundido Section—The next link south, the first or northern section of the recently completed Longitudinal Ry., between Pintados and Pueblo Hundido, [illegible] a distance of about 436 miles of meter-gage road, was formally turned over to the government by the contractors, MacDonald, Gibbs & MacDougall. The concession for the construction and operation of this road was first signed by the government on Apr. 23, 1910, with the Chilean Longitudinal Railway Construction Co., Ltd., and the Chilean Railway Finance Co., Ltd., which later transferred their rights to the Chilean Northern Railway Co., Ltd.

This latter company entered into a contract for the construction of the line with the Chilean Construction Co., Ltd., which in turn sublet the contract for the carrying out of the work to MacDonald, Gibbs & MacDougall. All of these companies are English, but an American, Judge Coyne, of Tennessee, was largely instrumental in securing the concession and in forming the company that will operate the road for a period of 25 years. The contract price for the construction of the road was $15,275,000. Most of the locomotives required for construction work and afterward turned over to the operating company were purchased in Germany. The reason for the purchase of most of this equipment from the Germans, as given to the writer by one of the contracting company, was that quick delivery could not be obtained from American builders and the lowest price obtainable from English builders was $1425 per locomotive (for Moguls) higher than the German price.

It was further stated, however, that these German engines have not proved first-class, and that the most of them will have to be scrapped soon. It might, therefore, be well for builders of motive-power equipment and rolling stock to keep in touch with the Chilean Northern Ry. Co., Ltd., the operators of the road, addressing them either at their London offices at 7 Princes St., E. C., or in Santiago, Chile, Calle Agustinas 718.

The railway from Pintados to Pueblo Hundido for the most part was of easy construction, traversing desert country and crossing the enormous nitrate deposits back of the ports of Taltal, Aguas Blancas, Antofagasta and Tocopilla, a route which allowed the permanent works to be of a comparatively simple nature. There are no tunnels and only one bridge in its entire length and the maximum gradient is 4%. The sharpest curve has a 100-m. radius. The rails are 50 lb. per yd. and the sleepers are native wood.

From this northern section the railway is continued over a section of meter-gage railway built by the Public Works Department of the government, a distance of about 160 miles to Copiapo.

[illegible] Section—From Coquimbo south to [illegible], a station on the [illegible] branch of the State Railways, about 140 miles from Santiago, the road was built (the rails were joined on Nov. 23 last, as mentioned above) by a French company, the Régie Générale de Chemins de Fer au Chili, having offices both in Paris and Santiago. The contract for the construction and operation of this road for a period of [illegible] years was signed by the government with the Howard Syndicate, Ltd. (another English concern), which in turn made a contract with [illegible] & Co. for the construction work. In March, 1911, due to financial difficulties, both the Howard Syn-

Fig. 4. Tunnel through the Andes Mountains on the Trans-Andean Ry. from Valparaiso to Buenos Aires

[illegible] and Griffin & Co. gave over control of the road to the French company.

This section is about 310 miles in length, meter gage, and the contract price for its construction was $20,130,000. The road was a most difficult one to build, presenting many engineering problems. There are many tunnels, the longest being the Espino tunnel, 1730 ft., bored through solid rock and at an elevation of 4800 ft. above sea level. There are also three other good sized tunnels just north of Cabildo, one of 4150 ft., one of 3380 ft., and one of 2500 ft., besides a number of smaller ones,

COPYRIGHT, [illegible]

Fig. 5. Bridge on the Cabildo R.R. Branch of State Rys.

making construction expensive, for which the contractors [illegible] to have lost considerable money.

At the station of Limahuida, about 75 miles north of Cabildo, a section about 14 miles in length built by the Public Works Department to connect the interior [illegible] of Illapel with the port of Los Vilos is used to connect Limahuida with Illapel. Between San Marcos and [illegible] [illegible] the port of Coquimbo another section of 180 miles built by the Public Works Department is utilized. [illegible] about 72 miles of this [illegible] is 5 ft. 6-in. gage, a third rail has been laid to meter gage. Just north of Cabildo at the station of Palquico, the road is built as [illegible] for a distance of 10 miles, although the grades [illegible] from 3% to 6%. Just north of Illapel, the track [illegible] for a distance of about 16 miles [illegible] a section of [illegible] The grade [illegible] the Espino tunnel mentioned above. It is stated that this rack section cost $[illegible] per mile to build.

Most of the rolling stock and motive-power equipment used in the construction of this section was also purchased in Germany and Belgium, although some [illegible] locomotives, built by the [illegible] Locomotive Corporation of [illegible], were used in the construction of the rack sections.

The Regie General des Chemin du Fer au Chile, the builders, although now having difficulties with the government over the question of settlement, caused by their construction losses, will, it is fully believed, carry out their contract to operate the road for 30 years; and if so, they will be obliged to purchase considerable motive-power equipment and rolling stock.

From Cabildo, the end of the southern section of the Longitudinal to the Capital, Santiago, the Pan American route follows the recently built branch of the State Rys. to Calera, a distance of 72 miles, where it joins the main line of the State Rys. between Valparaiso and Santiago, all of which is 5-ft. 6-in. gage.

Effect of Railway Development on Mining and Industries

Already the opening up of the southern section of the Longitudinal has stimulated the mining industry in the district between Cabildo and Copiapo, and as both north and south sections traverse an extensive mineral zone containing copper, iron, silver, nitrate, borax, etc., it is fully believed that the road will be the means of largely developing these industries in a section that has been heretofore but little worked.

Nitrate Works—The Longitudinal Ry. is crossed at several points by private railways, mostly English, which serve the many nitrate works, carrying nitrate to the ports of Pisagua, Caleta Buena, Junin, Tocopilla, Mejillones, Antofagasta, Caleta Coloso, Taltal, and Chanaral. This nitrate industry is Chile's most important one. The export duty on the $2\frac{1}{2}$ to 3 million tons of nitrate exported annually, mostly from the above ports, is about 60% of the revenue of the entire country, and the nitrate is about 70% of all the exports.

The present price of nitrate alongside vessel in the above ports is $1.90 per quintal (100 lb.), and the export duty on the same is $12.50 per [illegible] ton. It is said there is sufficient nitrate in Chile to last another 75

COPYRIGHT, [illegible]

Fig. 6. View of Nitrate Works on Longitudinal Ry.

years, and as the Longitudinal Ry. now taps numerous nitrate fields, it is expected that these lands, which are owned by the government, will soon be disposed of by public sale, as provided by law, to be worked by private parties. With the aid of the connections with English nitrate lines, mentioned above, the Longitudinal Ry. and

the various intersecting government-owned railways will also be of great aid in the development of the important and growing copper and iron mining industry of the country.

Copper Mines—The American promoters, the Guggenheims, have for many years past been large buyers and shippers of copper ore from Chile to the States and for the past few years have worked a large mining property, including a smelter and 46 miles of railroad, in the south under the name of the Braden Copper Co.* The Braden Ry. is a heavy-grade road of but 2-ft. 6-in. gage connecting Rancagua on the main line of the Chilian State Rys. with the mines at Teniente and is operated by eight 42-ton Shay-geared locomotives.

Just recently the Guggenheims, under the name of the Chile Exploration Co., have purchased a very large copper property back of the small port of Mejillones, 12 miles north of Antofagasta and it is said they will invest an enormous sum of money in its development, among other things building a 40-mile meter-gage railway from Mejillones, and 11 miles of standard-gage railway about the plant.

A syndicate headed by William Braden, formerly President of the Braden Copper Co., before it was sold to the Guggenheims, has recently acquired large copper properties back of Chanaral, to which property they will, it is said, soon build a railroad and erect a smelter, etc.

There are also fair sized smelters at Gatico (near Antofagasta) and Guayacan (near Coquimbo), both operated by Chilian companies, and it is expected, due to the fact that shippers will now be able to get their ore to the coast at a much lower rate than formerly by making use of the Longitudinal Ry., that there will be a couple or more new smelters erected near Antofagasta.

*Described in "Engineering News," May 22, 1913.

Arica-La Paz Ry.—Large quantities of copper ore are now shipped regularly from the port of Arica, in the extreme north, but this ore is mostly from the Corocoro mines in Bolivia and comes into Arica over the recently finished Arica-La Paz Ry.*, which was opened to traffic in July last, having been built by the English contractors, Sir John Jackson & Son, after a Chilian company, the Sindicato de Obras Publicas, had failed. The locomotives in use are German—Esslingen, Borsig and Henschel—and the cars are all steel, both passenger and freight, from the Middletown Car Co., Middletown, Penn. At present there is but one through train a week over the road in either direction, and while the traffic is bound to increase it will be many years before it will be an important freight road or one that will pay. In fact, it was built mainly for political reasons.

Courtesy Bulletin of Pan-American Republics
Fig. 7. Railway Bridge over the River Lute, on the Antofogasta & Bolivia Ry.

Antofogasta & Bolivia Ry.—The Antofogasta & Bolivia Ry., a 2-ft. 6-in. gage railway running from Antofagasta to Oruro, Bolivia, a distance of 574 miles, crosses the Longitudinal or Pan American route at Baquedano, and is an important factor in the development of several small copper mines near Calama and the very important group at Collahuasi, on a short branch road at an elevation of 15,814 ft. above sea level. At San Pedro station (193 miles from Antofagasta and 10,700 ft. above sea level) are situated the collecting reservoirs, blasted out of solid rock, built by the railway company at an expense of about $5,000,000 to supply the town of Antofagasta, the nitrate works and its own service with water, for no other fresh water can be obtained except by condensing the sea water.

The main railway has to reach an altitude of 13,000 ft.

*Described in "Engineering News," Nov. 27, 1913.

is 920 miles. At 12,000 ft., mile 240, it runs alongside a wonderful lake of borax, 24 miles long, owned and worked by the Borax Consolidated Co., and said to be the largest single deposit of borax in the world, and the main source of the world's supply.

At about 295 miles from Antofagasta, the road crosses the river Loa on what is said to be the highest viaduct in the world and certainly one of the most interesting engineering structures in the world. The level of the rails on the viaduct is nearly 10,000 ft. above the sea and at a height of 336 ft. above the surface of the waters of the river below. The viaduct consists of six lattice-girder spans, of 80 ft. each in the clear, supported on steel trestle towers. At Huari, mile 497, there is the mysterious fresh water lake Poopo, which receives 212,000 cu. ft. of water per minute, and only 2000 cu. ft. flows out of it. There are also many other wonders of nature along this line, among them the snow-capped volcanoes of San Pedro and San Pablo, from the former of which there is a steady column of smoke constantly ascending, and the giant Ollague, over 20,000 ft. high.

There are many branch lines (some recently built) tapping the main road serving the nitrate works and copper mines adjacent; the principal ones are those to the Aguada nitrate fields, a distance of 70 miles, to the port of Mejillones, and to the Collahuasi copper mines, a distance of 60 miles. There is also a private railway from Uyuni, mile 373, to the famous Huanchaca silver mines, now being worked by an American company.

The principal branches of the Antofagasta & Bolivia Ry., however, are the recently completed ones from Rio Mulato (mile 443) to the old Bolivian city of Potosí and from Uyuni (mile 379) to Tupiza, near the Argentine border of Bolivia, a distance of 113 miles. The former railway, while but 108 miles in length, was by far the most difficult and expensive to build as it traverses broken, wind-swept and often snow-covered country almost its entire length, winding around mountain after mountain and through deep cuttings through solid rock, and, at mile 51 from Rio Mulato the rails reach an elevation of 15,814 ft. above the sea, making this the highest railroad in the world. Both of these roads were built by American contractors.

The Antofagasta & Bolivia Ry. has also recently built a meter gage railway from Oruro, the end of their main line in Bolivia, to Cochabamba, a distance of 124 miles.

About four years ago, this company acquired the control of the road built by an American company from Oruro to La Paz, a distance of 127 miles, which, with the branches mentioned above, gives a big and growing traffic, with the result that it has been decided to widen the gage to meter and substitute 70-lb. rails for the old 60-lb. rails now in use.

Courtesy Bulletin of Pan-American Republics

FIG. 8. PORT AND RAILWAY TERMINAL AT TALCAHUANO

For the increasing traffic and the change in gage, the company will soon be in the market for rolling-stock equipment, cars, rails, etc. While the company is English, with head office in London, offers by American manufacturers desirous of doing business with it will undoubtedly receive every consideration. It was reported some little time ago that the control of this road had been obtained by the Brazil Ry. interests (offices at 71 Broad St., New York), but the facts are that while the Farquhar interests did obtain about $10 million worth of stock of this road, they were forced to hypothecate it with English banks almost immediately, and the control of the company is still strictly English.

IRON MINES.—The Bethlehem Steel Co. is also now building a short railroad from its recently acquired iron-ore deposits at Tofo, near Coquimbo, to a small port just north. It is stated that these deposits, acquired

from a French company, contain over 100 million tons of about 67% ore, mostly on the surface.

Railways South of Calera and Santiago

From Calera south, the Pan American route is continued over the main line of the Chilian State Rys. (5-ft. 6-in. gage) to Osorno, a distance of 665 miles. From Osorno to Port Montt, the end of the habitable part of Chile, a distance of 79 miles, the road was only recently finished and turned over to the government. It also is 5-ft. 6-in. gage.

From the port of Lebu, about 300 miles south of Valparaiso, a road of 101 miles in length, 5-ft. 6-in. gage, to Los Sauces, on the main line of the State Rys. is being built under government guarantee by an English company, the Chilian Eastern Central Ry. Co., Ltd.; but this company is now temporarily financially embarrassed and active construction work has been stopped. This road, when finished, will open up a rich mineral and farming section for development, and give a better outlet for the large quantities of good coal mined at and near Lebu.

On the island of Chiloe, just south of Port Montt, the Chilian Government has just finished the construction of a 62-mile, 75-cm. gage railway from Ancud to Castro.

Smaller Railways

Several shorter railways have also been built for the government during the past two years, such as the 17-mile meter-gage railway connecting the port of Papudo, north of Valparaiso, with Ligua on the Longitudinal Ry. A considerable mileage has been built by private companies, especially in the nitrate section, but enough has been written here to show conclusively that Chile has progressed rapidly with railroad building during the past few years, and while this rate of progress will not be kept up there are still quite a number of roads which the government have ordered surveyed and will very likely order to be built soon. Among the projects now pending is the proposed railway from Santiago to Valparaiso via Casablanca to avoid the heavy grades on the present line. They are also studying the question of electrification of the present road between these two cities, and there is some talk of this work being carried out instead of building the road via Casablanca, but due to the heavy initial cost of electrification and the present bad economic condition of Chile, this latter plan will probably fall through.

Trans-Andean Railways

While there is at present one trans-Andean railway connecting Valparaiso and Buenos Aires,* the Chilian and Argentine Governments contemplate the building of two other roads to connect these countries, one in the north from Caldera to Buenos Aires putting the arid nitrate section of Chile in touch with the rich agricultural section of the Argentine, and another line in the south from Valdivia to connect with the Argentine Great Southern Ry. at San Martin de los Andes, on the Chilian border.†

Either of these lines would reduce the climb over the present trans-Andean road about one-half, which would make them practical freight routes, while the present railway can only be used profitably for passenger and light freight and express service. The northern line will require a tunnel of only 1640 ft. to pierce the Andes at the point selected; while to build the present trans-Andean line a tunnel over a mile long at an elevation of almost 12,000 ft. was necessary.

The Chilian State Rys., not including the roads recently built and mentioned in this article, have about 600 locomotives and over 7000 cars in use and the government will buy in the near future 100 more locomotives and over 1000 cars.

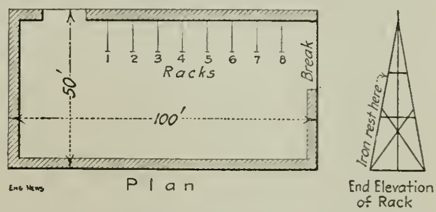
†Surveys for this railway described in "Engineering News," Feb. 12, 1914.

A Brick Wall Wrecked by an Interior Blow—A three-story brick wall of a large warehouse owned by the Huey & Philps Hardware Co., Dallas, Tex., was wrecked in a remarkable manner when a wood rack for holding iron bars, rods, slats, etc., failed under load. Tracks of the Texas & Pacific Ry. pass the building on the side which failed, and it is suggested that vibration caused by a heavy freight



(The racks were built of timber in the manner shown. The collapse of rack 1 with its load caused the other racks to fall successively, from impact.)

Fig. 1. Plan of 3rd Story, and End Elevation of Supporting Frame for Steel Rack, Etc.

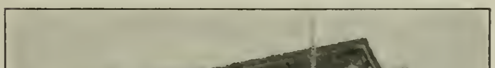


Fig. 2. Showing Break in Wall

train probably unbalanced the load on rack No. 1, which was the first to fall, so that it collapsed against No. 2, and so on successively, finally breaking down the wall. The manner of this accident is shown in Fig. 1, and the result in Fig. 2. The accident occurred during the night, July 10, and no one was injured.

Changes and Enlargements of the Water-Purification Plant, Youngstown, Ohio

Extensive changes of an interesting character are now being made in the water-purification plant of Youngstown, Ohio. The present settling reservoirs are to be replaced by much larger ones, and the old reservoirs are to be used for new mechanical filters above and for clear-water storage below. The existing mechanical filters are to be raised to a level suggested by the flood of 1913, and during the process their piping and gutter systems will be rearranged. The flow of the Mahoning River is to be regulated by the construction of a large dam, and a new pumping station is being built adjoining the filters.

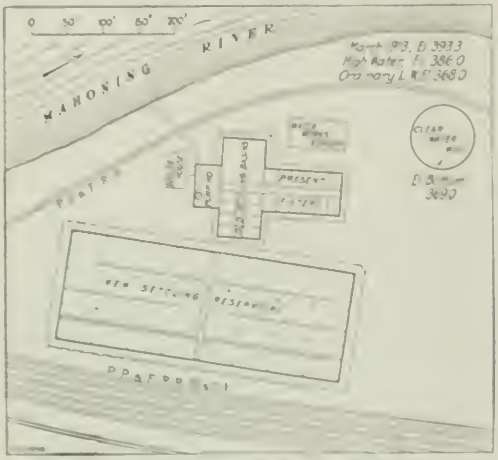

Fig. 1. General Layout of Water Purification Plant, Youngstown, Ohio

Increase of capacity is demanded by the growth of the city. The daily consumption is increasing each year by nearly a million gallons. The existing plant (Fig. 1), comprising twelve 1,000,000-gal. units, is overtaxed by the present requirements of the city. To meet future needs a set of 16 additional units of the same size is being built.

The principal element of trouble in the raw water is high iron content and general turbidity. The old basin, 55x135 ft., was far too small to give an adequate sedimentation period, and the filters, overloaded by their normal duty, were further taxed by having to handle a water insufficiently cleared in the settling basin. Two new settling basins were laid out, close alongside the filter plant, of aggregate dimensions 150x400 ft., with about eight times the area and three times the length of flow available in the old basin. The new basins (Fig. 2) are wholly of reinforced-concrete construction, with buttressed outer walls and continuous slab floor. The basins are 19 ft. deep.

When the new basins were projected, the elevations of the old basin and filters were adopted for the new work. The flood of March, 1913, however, 8 ft. above any prior record, rose some $2\frac{1}{2}$ ft. over the filter-house floor, and it was then decided to raise the new work $3\frac{1}{2}$ ft. for safety against future great floods. Part of the excavation for the first of the new settling basins had already been carried down to the footing-level first intended, and this was refilled to the new elevation. This basin is completed and in operation, and concrete work on the walls and floor of the second basin is in active progress.

The old basin, $20\frac{1}{2}$ ft. deep, gives a depth of 24 ft. up to the new level of top, for filter and clear-water-basin construction. A reinforced-concrete slab and beam floor, on columns 16 ft. on centers longitudinally, is to be built $9\frac{1}{2}$ ft. below the new top of the side walls (Fig. 3). Below this a clear height of $11\frac{1}{2}$ ft. will be available for clear-water storage. The floor will carry the 16 new filters, 11 ft. 8 in. by 22 ft. 3 in. inside, $8\frac{1}{2}$ ft. deep, separated by a central longitudinal distribution gallery 10 ft. wide in the clear.

Removal of the baffle walls in the old basin is now going on, to be followed by construction of the new bottom slab and lining, intermediate floor and filters. When these

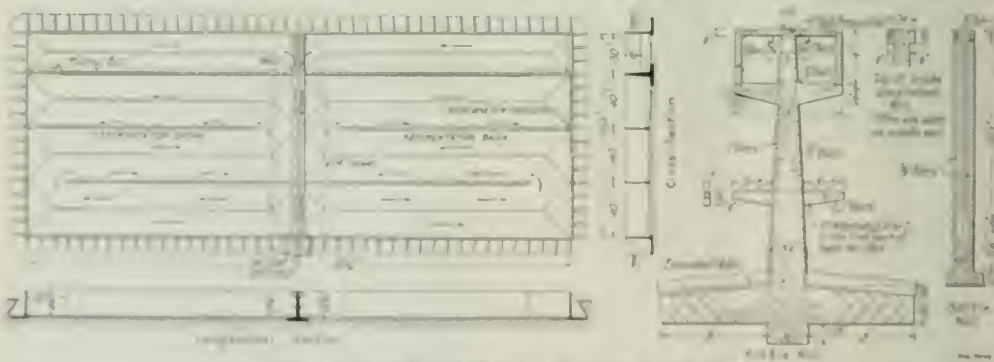

Fig. 2. New Water Settling Reservoir, Youngstown, Ohio

Fig. 3. Converting Settling Basins into Mechanical Filters and Clear-Water Basin, Youngstown, Ohio

... completed, the old filters are to be put out of service and rebuilt to a level 3½ ft. higher, and with new water feed and collecting systems, all as shown by Fig. 4.

Removal of the pumping station from the east bank to a location alongside the filter plant is being prepared for

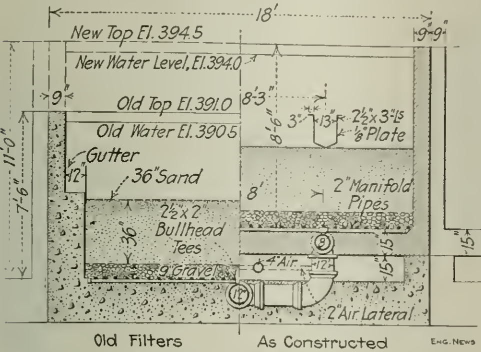

Fig. 4. Reconstructing a Mechanical Filter at Youngstown, Ohio

by foundation work at the new site. A contract was let recently for the chimney of the new station, a reinforced concrete stack 10x200 ft. (238 ft. high above foundation). Soft clay and a thin stratum of quicksand underlaid by hard gravel form the subsoil of the site. The foundations will be carried down to the gravel, some 20 ft. below original ground surface.

The contract for the filter-plant construction is being carried out by W. H. Henderson, of Youngstown. Heller Bros. are contractors for the pumping station. The Weber Chimney Construction Co. will build the new stack. Contracts for the pumping machinery have not yet been let.

The present filter equipment is said to be producing a highly satisfactory effluent. Treatment with hypochlorite has not been used at Youngstown, and is not contemplated. In April, the tests of the filtered water are reported as showing only two 10-c.c. samples with B. Coli, no coli found in 1-c.c. samples. The interval between washings averages 24 hr. with the new settling basin in operation, whereas before that period the worst conditions called for washing every 4 hr.

F. M. Lillie is City Engineer of Youngstown, and J. S. Lewis is Superintendent of Water.

A Large Open-Air Swimming and Wading Pool

An open-air public swimming and wading pool has been built in the Fair-Ground Park at St. Louis, Mo., which is said to be the largest ever built. The pool is approximately circular, but is divided into two unequal parts by a wide promenade, as shown in Fig. 1. The pools, sand beach and dressing rooms occupy about five acres.

The larger portion is the swimming pool, 440x270 ft., with a maximum depth of 10 ft. at the driving platform; its area is 99,724 sq.ft. and it holds 751,000 gal. of water. It has a 4-in. and a 6-in. supply main under 30-lb. pressure, and a 15-in. and 16-in. drain; it can be filled in 44 hr. and emptied in 20 hr. The smaller portion is the wading pool, 315x120 ft., with a maximum depth of 42 in. It has an area of 31,520 ft. and contains 361,500 gal. of water. It is supplied by a 6-in. main under 30-lb. pressure, and has a 12-in. drain, so that it can be filled in 5½ hr. and drained in 2 hr. The bottom is of reinforced-concrete slabs 2½ in. thick, laid on a bed of well-rammed cinders, and having expansion joints spaced 8x20 ft. These joints are constructed as shown in Fig. 2. The diving platform also is of reinforced concrete.

The dressing-room building contains 236 dressing rooms, besides children's rooms, locker rooms, toilets, shower baths, etc. It is so arranged that bathers going to the pool walk through a shower bath, while those coming from the pool walk through a shallow concrete foot

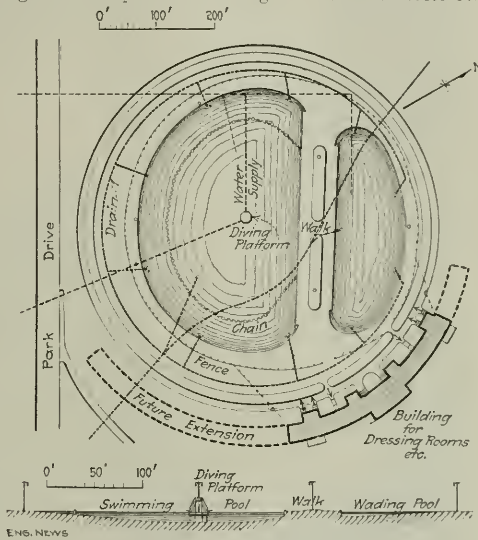

Fig. 1. Plan of Swimming and Wading Pool in the Fair-Ground Park, St. Louis, Mo.

bath, to prevent tracking sand and dirt into the rooms. On the opening day the pools were used by 10,000 persons.

The pools and building were designed by Geo. E. Kessler & Co., landscape architects, St. Louis, and were built under the direction of Nelson Cunliff, Superintendent of Construction of the Park Department. All work on the pools was done by the park employees, and the contract
